THE APPLICATION OF THE MOLECULAR ROTATION TO THE DETERMINATION OF THE VALUE OF CINCHONA BARKS.

BY DR. E. J. DE VRIJ.

The strong deviation of the plane of polarization in different direction or different intensity by all the known cinchona alkaloids, induced me to try to apply this action to test the value of the cinchona barks; and, although I readily confess that my experiments in this direction are far from being complete, yet the results already obtained seem to me interesting enough to fix attention on this new method of investigation, so that their publication may, perhaps, afford some interest.

Before proceeding to the description of my method, it may, perhaps, not be superfluous to state the principles upon which it is based.

The molecular rotations of the cinchona alkaloids which are known with certainty are the following:—

Quinine:
 in alcoholic solution [α]j=184°·35 ↺ } De Vrij and
 in acid solution . . [α]j=287°·16 „ } Alluard.
Quinidine:
 in alcoholic solution [α]j=250°·75 ↻ Pasteur.
 in acid solution . . [α]j, not yet determined.
Cinchonine:
 in alcoholic solution [α]j, not yet determined.
 in acid solution . . [α]j=190°·40 ↻ Bouchardat.
Cinchonidine:
 in alcoholic solution [α]j=144°·61 ↺ Pasteur.
 in acid solution . . [α]j, not yet determined.

Besides these four alkaloids, about whose existence all chemists agree, and whose properties are well known, there exists in the cinchona barks still a fifth alkaloid, which is amorphous, soluble in ether, and whose compounds with acids are equally amorphous. I have long been uncertain if this alkaloid has an action on the plane of polarization, and it is only very recently that I became persuaded that it deviates from that plane slightly to the right. I have, however, not yet succeeded in determining the exact amount of this deviation, because this alkaloid is always yellow-coloured, and very difficult to obtain perfectly pure.

It is clear from the preceding that the different cinchona alkaloids possess a different rotation, and that some of them deviate the plan of polarization in an opposite direction. Therefore, in examining optically the combined alkaloids of any bark, three cases can occur:—

I. The alkaloids may prove inactive, viz. to exercise no deviation at all. This case, although not yet observed by me, may present itself, if the relative quantities of the alkaloids are such that their opposite deviations neutralize each other.

II. They are turned to the right (dextrogyre = ↻) if the quantity of quinidine, cinchonine or amorphous alkaloid exceeds that of quinine or cinchonidine.

III. They are turned to the left (lævogyre = ↺) if the quantity of quinine or cinchonidine exceeds that of the other alkaloids.

From the facts mentioned, it appears that the deviation produced by quinine is different, depending on its being observed in solution in alcohol or in a diluted acid. It is very probable that this difference exists in the same direction with the other alkaloids, and its determination will be very desirable.

Taking now in consideration that, of the five mentioned alkaloids, two of them, viz. the quinine and the amorphous alkaloid, are very soluble in ether, whilst the three remaining alkaloids are sparingly soluble in this liquid; it follows that, if the alkaloids are treated with ether, the deviation exercised by the part insoluble in ether will prove to be very different from that observed before. This different deviation may be the following:—

(1.) No deviation, if the part insoluble in ether contains enough of cinchonidine to neutralize the opposite deviation of the cinchonine.*

(2.) Deviation to the right (dextrogyre) if the part insoluble in ether consists of cinchonine or quinidine, or both of them, or if their quantity is superior to that of the eventually present cinchonidine. The intensity of the deviation may throw some light upon this alternative.

(3.) Deviation to the left (lævogyre), if the part insoluble in ether consists either totally or chiefly of cinchonidine. In this case the intensity of the deviation will equally throw light upon the alternative.

The great difficulty with these observations consists in the difficulty to obtain solutions of the alkaloids which are not too much coloured. The first

* As quinidine deviates to the right like cinchonine, it can equally neutralize the deviation to the left of the cinchonidine. It is, however, very rare that cinchonidine and quinidine occur in the same bark. Till now I have only found one example of this combined occurrence, viz. in the bark of the hybrid from *C. Calisaya* and *C. Pahudiana* (the so-called *C. Hasskarliana*, Miq.), in which bark I found the four alkaloids, together with the amorphous alkaloid soluble in ether.

requisite to measure accurately the deviations is that the solution is colourless, and till now I have not yet succeeded in obtaining this desideratum, but have been obliged to be satisfied by obtaining solutions which had a slightly yellow colour. I obtained these solutions as follows:—After ascertaining the total amount of alkaloids in a bark, the alkaloids were dissolved in weak acetic acid, and to this solution added a few drops of basic acetate of lead. After separating the lead by a current of sulphuretted hydrogen the liquid, much discoloured by the precipitated sulphide of lead, was filtered, and the alkaloids precipitated by caustic soda. The precipitate being washed and dried, one may proceed to prepare the solution for the optical observation. The alkaloids are accurately weighed, and the determined weight called p. This quantity is dissolved in diluted sulphuric acid, and the volume of the solution accurately measured.* This volume is called V, and filtered immediately into the tube, in which it will be observed. This tube has a length of 100 millimetres. After the tube has been completely filled and closed, and it has been ascertained that its contents are perfectly clear and transparent, it can be observed in the instrument.† If the different alkaloids are present in such quantities that their opposite deviations neutralize each other, the molecular rotation is $= 0°$, and this result needs only to be noted. If, however, a deviation is observed, this deviation is noted as $\alpha°$ = to the amount of degrees of deviation observed, either to the right or the left; for instance, $\alpha° = 3°$ ↷, or $\alpha° = 3°$ ↶, etc. One has now the necessary data to calculate the molecular rotation = $[\alpha]j$ of the mixed alkaloids by using the formula:—

$$[\alpha]j = \frac{\alpha° \, V}{p} \text{ ↶ or ↷‡}$$

After this determination another part of the alkaloids is treated with ether, and the deviation of the part insoluble in ether determined in the same way. By these two determinations one obtains two data, which, notwithstanding the still existing imperfections of the method, will prove to be of great utility in the investigation of cinchona barks, as may be seen by the following observations made by Dr. B. Simpson and myself.

A. Observations by Dr. B. Simpson.§

1. *C. Calisaya*, from Java.
   Stem-bark.

Total amount of alkaloids 1·36 per cent. $[\alpha]j = 160·5°$ ↷.
The alkaloids contained chiefly quinidine.

2. *C. Calisaya*, from Java.
   Bark from a branch.

Total amount of alkaloids 0·84 per cent. $[\alpha]j = 140°·6$ ↷.
The alkaloids contained a large amount of quinidine.

3. *C. Pahudiana*, from Java.
   Root-bark.

Total amount of alkaloids 1·5 per cent. $[\alpha]j = 26°·35$ ↶.

4. *C. succirubra*, from Darjeeling.
   Stem-bark of plants 3½ years old.

Total amount of alkaloids 5·6 per cent. $[\alpha]j = 13°·59$ ↶.
The alkaloids consisted of quinine, cinchonidine (both lævogyre), cinchonine and amorphous alkaloid (both dextrogyre).

5. *C. succirubra* from Ootacamund.
   Renewed bark (fourth harvest).

Total amount of alkaloids, 9 per cent. $[\alpha]j = 55°·5$ ↶.
The part insoluble in ether proved $[\alpha]j = 19°·8$ ↶.
The same alkaloids as in 4, but more cinchonidine and less cinchonine.

6. *C. officinalis* from Darjeeling.
   Stem-bark (one year covered by moss).

Total amount of alkaloids 7·68 per cent. $[\alpha]j = 56°·35$ ↶.
The part insoluble in ether proved $[\alpha]j = 13°·20$ ↶.
The same alkaloids as in 4 and 5, but much more quinine, of which the quantity amounted to 3·4 per cent.

7. *C. officinalis* from Ootacamund.
   Renewed bark (second harvest).

Total amount of alkaloids, 8 per cent. $[\alpha]j = 139°·49$ ↶.
The same alkaloids as in 6, but containing much more quinine; they were almost entirely soluble in ether.

B.—Observations by Myself.

1. *C. Calisaya* from Darjeeling.
   Bark of trees three years old.

Total amount of alkaloids, 3 per cent. $[\alpha]j = 120°·7$ ↷.
The part insoluble in ether proved $[\alpha]j = 174°·34$ ↷.
The alkaloids consisted of cinchonine, quinine, amorphous alkaloid and cinchonidine.

2. *C. hybrida* from Darjeeling, probably from *C. Calisaya* and *C. officinalis*.
   Bark of trees three years old.

Total amount of alkaloids, 3·24 per cent. $[\alpha]j = 178°$ ↶.
The alkaloids consisted of quinine, cinchonidine, amorphous alkaloid and very little cinchonine. The part insoluble in ether was too small for observation.

3. *C. succirubra* from Darjeeling.
   Stem-bark, sold in London in October, 1870.

Total amount of alkaloids 6 per cent. $[\alpha]j = 24°·1$ ↷.
The alkaloids consisted of cinchonidine, cinchonine, amorphous alkaloid and quinine.

4. *C. officinalis* from Ceylon.
   Bark sold in London in November, 1870.

Total amount of alkaloids 5·7 per cent. $[\alpha]j = 145°·8$ ↶.
The part insoluble in ether proved $[\alpha]j = 91°·96$ ↶.
The alkaloids consisted of quinine, cinchonidine, amorphous alkaloid and cinchonine. The quantity of pure quinine amounted to 3·7 per cent.

---

* Weight and measure are of the metric system.

† The instrument used by me is the polaristrobometer, of Wild. It is, however, clear that any other good instrument may be used.

‡ Although the sulphide of lead has a very favourable action in taking away a great part of the colour of the solution, its action is not the same with all kinds of bark. I am therefore unable to state with certainty the quantity of alkaloids which ought to be dissolved in a certain volume. It is desirable to make a solution which contains 0·1 of the alkaloids. This is, however, in general not possible, because of the too intense colour, wherefore the quantity of the alkaloids in the solution varies between 0·1 and 0·05.

§ These observations have been made by Dr. B. Simpson, Surgeon, of the Bengal Army, in my laboratory at the Hague, in February 1870.

5. *C. Calisaya* from Java.
Bark sold in April, 1870, at Amsterdam, under the name of—
"Java koningskina, No. 1."
Total amount of alkaloids, 3·21 per cent. $[\alpha]j = 96^\circ\cdot3$ ↶.
The alkaloids consisted of amorphous alkaloid, quinidine, cinchonine and a trace of quinine.

6. *C. Calisaya hybrida* from Java (*C. Hasskarliana*, Miq.).
Bark sold in April, 1870, at Amsterdam, under the name of—
"Java koningskina, Nos. 2 and 3."
Total amount of alkaloids 3·125 per cent. $[\alpha]j = 50^\circ\cdot2$ ↷.
The alkaloids consisted of quinine, quinidine, cinchonine, cinchonidine and amorphous alkaloid.

7. *C. Calisaya* from Java.
Bark sold in April, 1870, at Amsterdam, under the name of—
"Java koningskina, No. 4."
Total amount of alkaloids 2·47 per cent. $[\alpha]j = 20^\circ$ ↶.

8. *C. Pahudiana.*
Bark sold in April, 1870, at Amsterdam under the name of—
"Bruine Javakina." *
Total amount of alkaloids 1 per cent. $[\alpha]j = 138^\circ$ ↷.
The alkaloids consisted of quinine, cinchonidine and amorphous alkaloid, whilst the presence of cinchonine was dubious.

9. *C. Calisaya* from Bolivia.
Eastern Bolivian bark.
Total amount of alkaloids 4 per cent. $[\alpha]j = 138^\circ$ ↷.

Notwithstanding the defects still adhering to the method, I feel certain that it will prove to be an important element in the examination and classification of the Cinchona barks.

The Hague, 20th April, 1871.

PEPSIN.

BY G. A. ZWICK.

So much has been said and written about this remedy, that the subject would seem nearly exhausted. I desire, therefore, only to communicate the result of a few experiments just completed; these, with the investigations of others, may perhaps lead to the adoption of a formula for a preparation of this article in the next edition of the U. S. Pharmacopœia.

1st. A fresh stomach of a pig was emptied and the slimy mucous substance scraped off, spread upon a glass plate and dried.

2nd. The mucous membrane (scraped off as above) was dissected from the body of the stomach, cut up into moderately fine pieces. This weighed 8 oz.; it was digested with ℥viij pure glycerine (acidulated with ʒij muriatic acid) for twelve hours, expressed, and more glycerine added till ℥viij were again obtained. This fluid was set aside and separated after a few days; the clear was poured off and filtered, warming it a little to facilitate filtration.

3rd. Another pig's stomach was cleanly washed and wiped, macerated with water (acidulated with hydrochloric acid) for twelve hours, this water poured off and more added, washing and rubbing the membrane well. All these washings and the first infusion of twelve hours, making 24 ounces, were filtered, precipitated with acetate of lead, and treated with sulphuretted hydrogen, being the process mentioned in the U. S. Dispensatory, but the liquid pepsin was evaporated to ℥viij only, not to dryness.

To compare these preparations they were tried with coagulated albumen.

No. 1. Six-tenths ($\frac{6}{10}$) of a grain of the dry mucus dissolved 12 grains albumen.

No. 2. One fluid drachm of the glycerine preparation dissolved 12 grains of albumen.

No. 3. Five fluid drachms (ʒv) of the watery solution dissolved 12 grains of albumen.

The above result, however, does not represent the utmost solving power, excepting of No. 1. Nos. 2 and 3 suffered losses of pepsin. No. 2 lost pepsin on account of being digested and warmed while still in contact with the mucous membrane, and I am sure considerable pepsin was lost, as the mass became quite soft and pulpy. The process should be carried on cold. No. 3 lost some of the precipitate during washing. This process is not practicable in warm weather, as the liquors decompose rapidly.

Summing up my experience, I should take No. 2 as the process furnishing the most permanent preparation, being agreeable both to the eye and the palate of the patient. It has a bright, clear straw-colour, an agreeable bland taste and could be made double the above strength. It is not subject to the changes and other objections of the powders, is ready when it passes out of the hands of the apothecary, without further mixing, and not objectionable in taste to the most fastidious.—*Amer. Journ. of Pharmacy.*

SYRUPUS CALCIS LACTO-PHOSPHATIS.

BY WILLIAM NEERGAARD.

In the *Archives Générales de Médecine* for December, 1869, and for January and February, 1870, Dr. L. Dusart recommends the use of a new preparation, which he terms the lacto-phosphate of lime, in which the lime salt is dissolved in free lactic acid.

Dr. B. W. M'Cready, of Philadelphia, requested me to prepare a syrup containing that compound, and I adopted the following formula:—

Concentrated Lactic Acid, fl℥j
Magma of freshly Precipitated Phosphate of Lime, q. s.
Aquæ Fl. Aurant., fl℥iss
Aquæ Puræ, q. s. ad fl℥viij
Sacchari Albi, ℥xj.

Mix the lactic acid with 2 fluid ounces of water and saturate it with the magma. Put the liquid upon a filter and add the rest of the water until 8 fluid ounces of filtrate are obtained. Pour this upon the sugar, contained in a bottle; shake occasionally until solution is effected and strain. No heat ought to be applied, else the syrup assumes a milky appearance.

The syrup thus prepared contains between 2 and 3 grains of dry phosphate of lime in each fl℥, besides the lactic acid.—*Amer. Journ. of Pharmacy.*

* The barks mentioned under 5, 6, 7 and 8 are the first products from the Cinchona plantations in Java brought into the market for sale.

CHINESE BLISTERING-FLIES.

BY F. PORTER SMITH, M.B. LOND., M.R.A.S.

The entomology of China is not peculiarly rich, when we bear in mind its semi-tropical character as a climate. The extreme, or considerable, cold of the country proves fatal to the crowds of insects which infest the house and the field, but of which a mere salvage is saved to renew the sorts. In no country, however, is so much wealth gathered from the labours of insects as in China. The *Coccus lacca*, which produces the gum-lac; the *Coccus pehlah*, which secretes the spermaceti-like wax of Chinese pharmacy; the *Coccus manniparus*, which prepares honey-sugar; the silkworm; the diplolepis gall produced upon the oak-tree; and the nut-galls (*Wu-pei-tsze*) produced upon the *Rhus semialata* and *Rhus succedanea*, are instances, amongst others, of that ingenious turning to account of things which is a strong habit of the utilitarian Chinese.

Insects, a large class, called in Chinese classifications, *Ch'ung*, and including frogs, mollusks, etc., are consumed by the Chinese as internal remedies.

Centipedes, scorpions, pediculi, and many other larval or imaginal forms of insects, are swallowed in wine as antidotal, derivative, and revulsive remedies. An anomalous creature, called the *Hia-ts'au-tung-ch'ung* ("in summer a plant, in winter an insect"), is a capital sample of a Chinese pet medicine. It is the *Hepialus* moth, with the *Cordyceps Sinensis* (fungus) growing parasitically upon it.

Blistering-flies are largely used in China. They are employed as diuretics, and to produce criminal abortion, so that their sale to ordinary persons is scarcely legal, and their use for such a purpose heavily punished by the Manchu Code of China. The *Mylabris cichorii* (*Pan-mau*) the Telini fly of India, is largely used in the country, as in the composition of an eye-powder (*Yé-ming-sha*), commonly believed to be the dung of the bat. This insect is an excellent substitute for the *Cantharis* of European pharmacy. The *Cantharis erythrocephala*, a common European species, is met with in North China, but the *Cantharis vesicatoria* has not been met with.

Species of so-called *Epicauta* are met with in China, and are apparently called *Tsáu-mau*, or Zizyphus bug, from their resemblance to the fruit of that genus of so-called "dates." The genus *Epicauta*, known by their running more to legs and horns, is now generally put with *Lytta* and *Cantharis*.

Another kind of blistering-fly, new to European pharmacy, is the *Chú-kí*, or Ailanthus bug. It is called, literally, the "fowl of the *Ailanthus fœtida*," from the noise which it makes in common with other cicadaceous insects of the class *Homoptera*. It is also called *Hung-liang-tsze*, or "red lady-bug," a curious coincidence with the name of a common English insect, the ladybird. Several species or varieties of this insect are described or alluded to in the *Pun-ts'au-kang-muh*, or Chinese Pharmacopœia. The genus called *Huechys*, from the Chinese name for blood, is met with in Java, as well as in North and South China and other places. The head, thorax and legs are black; the prothorax is red; the eyes are very prominent; a large red bright spot on each side of the thorax above; the front pair of wings are dark-brown, appearing nearly black when closed on the back of the insect; the hind pair of wings are pale with brown veins; and the belly of the creature is of a bright vermilion-red colour. Mr. Frederick Smith, of the British Museum, informs me that Burmeister places this insect, which I have called the red cicada on page 237 of my work on Chinese materia medica, in the order *Cicadina*, family *Stridulantia*. This same gentleman also informs me that Olivier (Encycl. Méthod. v. 756) calls it the *Cicada sanguinolenta*, whilst Amyot and Serville describe it as the *Huechys sanguinea*. This latter name is redundant, as both the genus and species mean bloody. It would be better to call the Chinese species *Huechys vesicatoria*. One Chinese variety is called the "ash-coloured moth." The *chú-kí* is met with in Sechúen, Shansi, Honan and Hupeh, and frequents the *Ailanthus*, *Broussonetia (Morus) papyrifera* and several other trees. They are met with in great quantities in autumn, when they make a grinding noise, and are collected by the country people, who sell them, fresh, to the druggists at a few pence per pound. They are capable of raising a blister, but are much less powerful than the *Mylabris cichorii*, with which they are combined in the treatment of hydrophobia. The legs and wings are removed, and the bodies only used for medicinal purposes. They are recommended in the *Pun-ts'au*, as a remedy in barrenness, impotency, menstrual disorders, deficient lochia, lumbago, diseases of the eye, etc. The drug is curiously directed to be used as a vaginal suppository in female disorders. It is combined with olibanum, arsenic, sal ammoniac and rice-paste, as an application to struma of the neck. Their use in hydrophobia, along with the *Mylabris*, to produce strangury, is in accordance with Chinese theory that the bite of mad dog impregnates the person, who is not safe until the delivery of a fœtal dog by way of the urinary passages. Hydrophobia is with them the climax of the period of gestation, and they promote parturition by giving the *Huechys* and the *Mylabris* internally; or, rather, they endeavour to induce abortion, as the drug is administered in wine at once in such quantities as to cause violent strangury. Along with the blood and other substances passed by the patient they profess to find a little dog. The Chinese doctors reason well enough that dog-bitten people die, and may be fairly treated after any extreme fashion. From this it may be gathered that the people die after the remedy even more promptly than after the bite alone. The drug can, therefore, be scarcely recommended for trial in such cases. It is creditable that few remedies are highly vaunted in Chinese medical works for a malady which is not common in China, where dogs are as plentiful and plaguy as in Constantinople. These blistering cicadas keep very badly, and, therefore, often disappoint the purchaser in China, where drugs are badly treated, like the patients.—*Medical Times and Gazette.*

DUST AND SMOKE.*

After a few preliminary experiments illustrative of the polarization of light, Professor Tyndall adverted to the polarization of light by fine dust, by the sky, and by the coarser particles of smoke. In the former the direction of maximum polarization, as in the case of the sky, is at right angles to the illuminating beam. In the latter, according to the observations of Govi, the maximum quantity of polarized light was discharged obliquely to the beam. Govi's observation of a neutral point in such beam, on one side of which the polarization was positive and on the other side negative, was also referred to. The additional fact was then adduced that the position of the neutral point varied with the density of the smoke. Beginning, for example, with an atmosphere thickened by the dense fumes of incense, resin, or gunpowder, and observing the neutral point, its direction was first observed to be inclined to the beam *towards* the source of illumination. Opening the windows so as to allow the smoke to escape gradually, the neutral point moved down the beam, passed the end of a normal drawn to the beam from the eye, and gradually moved forward several feet down the beam. The speaker did not halt at these observations, they were introduced as the starting-point of inquiries of a different nature, and after their introduction the discourse proceeded thus:—

But what, you may ask, is the practical good of these curiosities? And if you so ask, my object is in some

* Lecture delivered at the Royal Institution, Friday evening, June 9, 1871.

sense gained, for I intended to provoke this question. I confess that if we exclude the interest attached to the observation of new facts, and the enhancement of that interest through the knowledge that by-and-by the facts will become the exponent of laws, these curiosities are in themselves worth nothing. They will not enable us to add to our stock of food or drink or clothes or jewellery. But though thus shorn of all usefulness in themselves, they may, by leading the mind into places which it would not otherwise have entered, become the antecedents of practical consequences. In looking, for example, at this illuminated dust, we may ask ourselves what it is. How does it act, not upon a beam of light, but upon our own lungs and stomachs? The question at once assumes a practical character. We find on examination that this dust is organic matter—in part living, in part dead. There are among it particles of ground straw, torn rags, smoke, the pollen of flowers, the spores of fungi, and the germs of other things. But what have they to do with the animal economy? Let me give you an illustration to which my attention has been lately drawn by Mr. George Henry Lewes, who writes to me thus:—

"I wish to direct your attention to the experiments of Von Recklingshausen should you happen not to know them. They are striking confirmations of what you say of dust and disease. Last spring, when I was at his laboratory in Würzburg, I examined with him blood that had been three weeks, a month, and five weeks out of the body, preserved in little porcelain cups under glass shades. This blood was living and growing. Not only were the Amœba-like movements of the white corpuscles present, but there were abundant evidences of the growth and development of the corpuscles. I also saw a frog's heart still pulsating which had been removed from the body (I forget how many days, but certainly more than a week). There were other examples of the same persistent vitality or absence of putrefaction. Von Recklingshausen did not attribute this to the absence of germs—germs were not mentioned by him; but when I asked him how he represented the thing to himself, he said the whole mystery of his operation consisted in keeping the blood *free from dirt*. The instruments employed were raised to a red heat just before use, the thread was silver thread and was similarly treated, and the porcelain cups, though not kept free from air, were kept free from currents. He said he often had failures, and these he attributed to particles of dust having escaped his precautions."

Professor Lister, who has founded upon the removal or destruction of this "dirt" great and numerous improvements in surgery, tells us of the effect of its introduction into the blood of wounds. He informs us what would happen with the extracted blood should the dust get at it. The blood would putrefy and become fetid, and when you examine more closely what putrefaction means, you find the putrefying substance swarming with organic life, the germs of which have been derived from the air.

Another note which I received a day or two ago has a bearing particularly significant at the present time upon this question of dust and dirt, and the wisdom of avoiding them. The note is from Mr. Ellis, of Sloane Street, to whom I own a debt of gratitude for advice given to me when sorely wounded in the Alps. "I do not know," writes Mr. Ellis, "whether you happened to see the letters, of which I enclose you a reprint, when they appeared in the *Times*. But I want to tell you this in reference to my method of vaccination as here described, because it has, as I think, a relation to the subject of the intake of organic particles from without into the body. Vaccination in the common way is done by scraping off the epidermis, and thrusting into the punctures made by the lancet the vaccine virus. By the method I use (and have used for more than twenty years) the epidermis is lifted by the effusion of serum from below, a result of the irritant cantharidine applied to the skin. The little bleb thus formed is pricked, a drop of fluid let out, and then a fine vaccine point is put into this spot, and after a minute of delay it is withdrawn. The epidermis falls back on the skin and quite excludes the air—and not the air only, but what the air contains.

"Now mark the result—out of hundreds of cases of revaccination which I have performed, I have never had a single case of bloodpoisoning or of abscess. By the ordinary way the occurrence of secondary abscess is by no means uncommon, and that of pyæmia is occasionally observed. I attribute the comparative safety of my method entirely, first, to the exclusion of the air and what it contains; and, secondly, to the greater size of the apertures for the inlet of mischief made by the lancet."

I bring these facts forward that they may be sifted and challenged if they be not correct. If they are correct, it is needless to dwell upon their importance, nor is it necessary to say that if Mr. Ellis had resigned himself wholly to the guidance of the germ theory, he could not have acted more in accordance with the requirements of that theory than he has actually done. It is what the air contains that does the mischief in vaccination. Mr. Ellis's results fall in with the general theory of putrefaction propounded by Schwann, and developed in this country with such striking success by Professor Lister. They point, if true, to a cause distinct from bad lymph for the failures and occasional mischief incidental to vaccination; and if followed up they may be the means of leaving the irrational opposition to vaccination no ground to stand upon, by removing even the isolated cases of injury on which the opponents of the practice rely.

We are now assuredly in the midst of practical matters. With your permission I will recur once more to a question which has recently occupied a good deal of public attention. You know that as regards the lowest forms of life, the world is divided, and has for a long time been divided, into two parties, the one affirming that you have only to submit absolutely dead matter to certain physical conditions to evolve from it living things; the others, without wishing to set bounds to the power of matter, affirming that in our day no life has ever been found to arise independently of pre-existing life. Many of you are aware that I belong to the party which claims life as a derivative of life. The question has two factors: the evidence, and the mind that judges of the evidence; and you will not forget that it may be purely a mental set or bias on my part that causes me throughout this discussion from beginning to end, to see on the one side dubious facts and defective logic, and on the other side firm reasoning and a knowledge of what rigid experimental inquiry demands. But judged of practically, what, again, has the question of Spontaneous Generation to do with us? Let us see. There are numerous diseases of men and animals that are demonstrably the products of parasitic life, and such disease may take the most terrible epidemic forms, as in the case of the silkworms of France in our day. Now it is in the highest degree important to know whether the parasites in question are spontaneously developed, or are wafted from without to those afflicted with the disease. The means of prevention, if not of cure, would be widely different in the two cases.

But this is by no means all. Besides these universally admitted cases, there is the broad theory now broached and daily growing in strength and clearness—daily indeed, gaining more and more of assent from the most successful workers and profound thinkers of the medical profession itself—the theory, namely, that contagious disease generally is of this parasitic character. If I had heard or read anything since to cause me to regret having introduced this theory to your notice more than a year ago, I should here frankly express that regret. I would renounce in your presence whatever leaning towards the germ theory my words might then have betrayed.

(*To be continued.*)

THE ÆSTHETICS OF LABELS.

BY JAMES R. MERCEIN.

"A good workman is known by his chips," says the old adage; a careful pharmacist is known, or should be, by his labels, say I. Sent out as they are upon multiform parcels to the homes of our customers, they pass beyond our reach and speak for themselves—and for us. It behoves us, then, to be very circumspect as to the outward adorning of our dumb representatives. A roughly cut, badly printed label, such as we too often see, is like a "shocking bad hat," on a well-dressed man, spoiling the *tout ensemble* and betraying the sloven. Pharmacists err in thinking their patrons inobservant of such seemingly small matters. The almost Egyptian mystery that surrounds the ordinary details of our profession baffles the looker-on, and he naturally judges us by our outward symbols and tokens, of which the label is the most familiar. *Ex pede Hercule*,—if by the brazen foot the ancients estimated the statue, let us see to it, that the labels, our representatives, shall be a worthy exemplar of our work. The form of the label is the first point to be looked at. A round peg in a square hole does not look more out of place than an ill-shaped or over-sized label, and yet every day you will see a huge bit of paper on a "wee little" bottle, or a diminutive scrap on a portly flagon, thereby neutralizing the good looks of both labels and vials. Of course there can be no definite rule as to proper sizes, but the pharmacist should train his eye and his taste intuitively to recognize the right proportions. Let him avoid exactly square labels, or those abortive attempts which resemble monumental tablets. Double lines in the border, and rounded tops will give a label, printed in black ink especially, a tomb-stone look that must be suggestive to the patient. Hogarth insisted that the curve was the line of beauty, but if he had seen the shield-shaped labels now in such common use for "Elixirs" and "Syrups," he would have retracted his assertion instanter. Tastes will differ, of course, but to my eye these pharmaceutic escutcheons are fearfully and wonderfully ugly. In fact, almost every irregular form of label, unless its matter is nicely distributed and its type selected with the greatest care, is apt to be very ungraceful. For steady use, the old-fashioned oblong label, in width not quite half its length, wears best and looks best. For packages, the strip label, long and narrow is preferable. Well printed and tied on, so that its upper edge lies on the edge of the fold, it sets off a handsome bundle.

An octagon looks well on pill-boxes, and is a relief from the almost inevitable circle.

But it is in the printed matter, its distribution and its types where improvement is sadly needed. Why pharmacists in the progressive age should persist in using the stereotyped phrases in vogue thirty years ago, the same old-fashioned type, the venerable mortar, alembic, and retort; why we should do these things because our fathers did so before us, is a mystery. The art of type-cutting presents us with so many varied forms of letters, that numberless combinations, novel yet elegant, can readily be made. The chief error with pharmacists is a tendency to over-crowd their labels with reading matter; one would think they were trying to advertise all their wares in this small space, and yet the truth is, beyond the publicity of name and address, the label is not an advertisement, but merely a voucher for the contents of the package. A few lines, terse and to the point, are far better than a crowded jumble of disjointed sentences. "A rivulet of text flowing through a meadow of margin" should be the rule, as every printer will tell you. Useless verbiage and common-place phrases should be avoided. "Fine drugs and chemicals constantly on hand," "physicians' prescriptions carefully compounded," etc. etc., should be treated with the respect due to old age—and laid aside. If we are good pharmacists, these antique puffs will be unnecessary; if we are poor ones, such stale bait will not lure customers.

The titles that pharmacists assume are, as a general thing, decidedly inappropriate, and needing amendment. There is no doubt that the words "Pharmaceutist," or "pharmacist," are more nearly correct as expressing our professional status, although some contend that these should be peculiar to graduates. Be this as it may, the nomenclature of to-day is wrong. "Druggist" means no more or less than a seller of drugs, crude or otherwise, and implies no skill. It puts us on a level with any tradesman who simply sells to gain; the word should be confined to wholesale dealers only. Even when yoked with "chemist," as it often is, it will not pass muster. How many of us can lay the slightest claim to being chemists, further than the ordinary requirements of every-day business will warrant the title; and yet we coolly force ourselves into the ranks of a profession that requires the life-long attention of a Liebig, a Berzelius, a Doremus, or a Bridges! "Dispensing chemist" is equally absurd, or even more so. Who for a moment, aided by the most vivid imagination, could picture the above-mentioned analysts dispensing senna and manna, or mixing a dose of oil! The term "apothecary" is so exclusively English, and refers to such a different mode of doing business, half medical and half pharmaceutical, that it is totally inapplicable here. "Pharmacist" expresses exactly what we are; is not so clumsy as "pharmaceutist," looks well on a label, and better than all, does not make us appear, like the jackdaw of the fable, in borrowed plumes. In closing this homily, it seems almost superfluous to hint at such inelegancies as pasting one label over another, or over the seam of a bottle; of putting it on crooked, or with ragged edges; but I feel that most of my pill-rolling brethren will bear me out in the assertion that these slips are too often made. "What is worth doing at all, is worth doing well," says another old adage.—*American Journal of Pharmacy.*

FLUID EXTRACTS AND THEIR MENSTRUA.*

BY EDWARD R. SQUIBB, M.D.

In continuation of the subject of Percolation and Economy of Alcohol, annually presented to the Association for some years past, the writer offers an abstract of the results of his last year's experience, premising that he has neither the time nor inclination—as time becomes more valuable—to defend his notions, judgment, or accuracy, or even to point out many of the deductions that might be drawn from the statements made as facts.

It is not uncommon to hear observant physicians say that they do not obtain results from the fluid extracts corresponding in the proportion of minim for grain to the drug which they represent; and pharmacists who use the officinal formulas must be aware that the drugs are not entirely exhausted by the processes given. A critical inquiry into this subject, in this direction, is the chief object of this paper.

A practical way to measure the rate and extent of exhaustion by percolation has long been needed, and the want of some simple and easy plan has, perhaps more than any other obstacle, stood in the way of accurate knowledge and progress in the art of percolation. After many trials, some of which were described in previous papers, the method by specific gravity has thus far proved the most satisfactory and successful. But when applied by the hydrometer, or by the ordinary specific-gravity bottle, with the necessary calculations, it is too abstruse and complicated for common usage.

It is to a more plain and simple application of the principle of specific gravity that attention is now to be directed, and the formula may be stated as follows:—In

*** Read before the American Pharmaceutical Association at the meeting at Baltimore, 1871.**

percolation the density of the percolate will vary from the density of the menstruum in proportion to the extent and rate of the exhaustion. It follows from this proposition that to measure the extent and rate of exhaustion, it is only necessary to measure the extent and rate at which the percolate varies from the menstruum at the beginning of a percolation and approaches to it at the end, absolute exhaustion being indicated by equal density—or equal weight of the same volume at the same temperature—of the menstruum and percolate. This measuring is usefully accomplished with sufficient accuracy by separating the percolate as it passes into successive portions of a pint each and weighing them. By subtracting from this the weight of a pint of the menstruum at the same temperature, a series of differences will be obtained expressing the extent and rate of exhaustion. When the exhaustion is practically completed, —it is never absolutely accomplished,—the residue is dried and weighed, and its weight subtracted from the weight of the substance as originally taken for percolation. The difference or loss in weight indicates the total amount of solid matter dissolved and removed by the menstruum. Then, as the sum of the differences in weight between equal volumes of the menstruum and percolate at the same temperature, is to the total amount of solid matter or extract dissolved out by the menstruum, so is each separate difference to the weight of solid extract in the portion of percolate which that difference represents. That is to say, the total weight or amount of solid extract being ascertained, the ratio of the differences in density is applied to it to obtain a ratio of the rate of exhaustion, and to ascertain the distribution of the total extract throughout the percolate.

This method, applied to nearly all the fluid extracts which are at present officinal, and to some others, has convinced the writer,

First. That the present officinal processes do not sufficiently exhaust the drugs to which they are applied; and,

Second. That these processes do not take the best way to attain the object. That the supposed advantage of using coarse powders is a delusion. That maceration is useless at the commencement of the process of percolation, but useful after the substance has been partially exhausted. That the menstrua are not always the best that could be selected, either for extracting the useful portions of the drug or for excluding the useless portions. That glycerine is preferable to sugar where either gives any positive advantage, but that anything like a general use of glycerine in fluid extracts is to be deprecated, as the advantages are more in appearance than reality.

(*To be continued.*)

Iron Alum as a Hæmostatic.—A correspondent of the *Lancet* recommends the use of a strong solution of iron alum in glycerine as admirably adapted for the arrest of profuse bleeding where no large vessel is to be seen and secured. For hæmorrhage from the gums it may be applied in powder on a piece of lint; bleeding from the nose may be checked by stuffing the nostrils with lint saturated in the solution.

The Effect of Climate and Soil on Plants.—As an example of the effect of a tropical climate and soil on British cultivated plants and their products, may be mentioned the fact of the introduction of some peppermint plants from the Mitcham fields into a plantation at Singapore. After being planted in their new tropical home in a situation fully exposed to the sun they grew very well, but not to the height they grow in this country; moreover, they refused to flower, and almost as soon as they had arrived at full growth they dried up, having an appearance of being burnt. They were also found to yield not more than half the usual quantity of essential oil, and that of a dark claret colour and of an inferior odour.—*Gardeners' Chronicle.*

THE PHARMACY BILL.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

A Meeting of the Council was held on Monday the 19th inst., for the purpose of considering the proposed Pharmacy Bill of 1871. There was a full attendance of members; Mr. Dobb, the President, in the chair.

The minutes of the previous meeting having been read and confirmed, the President introduced the subject which the Council had been called to discuss, by reading the Bill which had passed through the House of Lords, and stood for second reading, June 26th. In a few brief remarks he said he thought it was desirable that some action should be taken by this Council, and he would wish to take its sense of the desirability or otherwise of petitioning the House of Commons against the Bill.

Resolved—That this Council offer the most strenuous opposition to the proposed Bill, that a petition be drawn up for presentation to the House of Commons by George Hadfield, Esq., the senior member for the borough, and that Messrs. Wilson and Preston be delegated to represent the views of the chemists and druggists of this town and neighbourhood at the conference to be held in London.

Resolved—That the following letter accompany the petition and be also forwarded to the county and borough members individually:—

"Sir,—A petition, of which the enclosed is a copy, has been forwarded to the senior member for the borough of Sheffield for presentation to the House of Commons; the petitioners therefore respectfully solicit your opposition to any such partial enactment. The petitioners object that this 'Amended Pharmacy Act' should be construed as one with the 'Pharmacy Act, 1868,' the 16th clause of which reserves the right of apothecaries, veterinary surgeons, etc., who are thereby exempt from conforming to the regulations for the dispensing, selling and keeping of poisons. The Petitioners submit that any legislative action upon this subject should be strictly impartial, believing that persons registered under the 'Pharmacy Act, 1868,' as chemists and druggists are as duly qualified to dispense, sell and keep poisons as apothecaries, veterinary surgeons and medical students in the various public hospitals and dispensaries of Great Britain."

A second meeting of the Council was held on Tuesday evening, the 27th inst., at the rooms of the Association, at which it was reported that the petition, bearing the signature of seventy-two chemists and druggists of this town, had been duly presented.

The following (condensed) report was presented by the deputation:—

On Monday, June 26th, the deputation were honoured by an audience with George Hadfield, Esq., senior member for the borough of Sheffield. Your deputation urged upon the hon. member the several objections the great body of chemists had to the Bill already passed by the House of Lords, and read for the first time in the House of Commons. After a general conversation the hon. member promised his assistance. Your deputation also waited upon A. J. Mundella, Esq., junior member for the borough, on the same day, and repeated the objections to the Bill, and also to the principles contained therein, who said he would aid to the best of his power. On Tuesday, June 27th, your deputation waited upon H. J. Beaumont, Esq., member for the West Riding of Yorkshire, who also expressed much sympathy with the objects of the deputation. Your deputation were unable to obtain any interview with Viscount Milton, the other member for the West Riding, being out of town through severe illness. Your deputation also sought an interview with S. Plimsoll, Esq., member for Derby; but failing to meet with him, a letter was dispatched to his address. Your deputation, in conclusion, desire to record the kind and affable manner in which they were received by one and all the members of Parliament with whom it was their pleasure to come in contact. Your deputation feel that the course adopted by the Council has met with great success and encouragement.

Mr. Dobb proposed that the best thanks of this Council be given to Messrs. Wilson and Preston for the very energetic and admirable manner in which they had carried out the views of the Council. This was seconded by Mr. Radley, supported by Mr. Cocking and Mr. Ward, and carried unanimously. This concluded the business of the meeting.

BOLTON DISTRICT ASSOCIATION OF CHEMISTS AND DRUGGISTS.

A Meeting of the committee of this Association was held on Tuesday, June 20th, to consider the desirability of taking steps to oppose the passage through the House of Commons of the Pharmacy Bill, 1871, when it was unanimously decided that the petition received from the Manchester Defence Association, and which had been signed by almost every member of the trade in the district, should be forwarded to our senior Member for presentation, together with the following resolution:—

"That the petition, signed by almost every chemist and druggist in Bolton, Farnworth, Atherton and Tyldesley, be forwarded to John Hick, Esq., M.P., as senior Member for this borough, for presentation in the House of Commons, and that Lieut.-Colonel Grey, M.P., be supplied with a copy, and earnestly requested to support it.

The committee also beg to submit that the feeling of the whole trade in this district is most decidedly against the imposition of such an uncalled-for interference with the rights and liberties of persons conducting the business; and when it is considered that statistics prove the gross average of deaths through either misadventure or carelessness to be only 1½ persons per annum for the whole population of the kingdom, there is surely no sufficient reason for such vexatious proceedings. This feeling is most forcibly expressed in the following extract from a resolution forwarded for presentation to the Pharmaceutical Council in April last:—

"That the poisons regulations proposed by the Pharmaceutical Council are at the present time quite unnecessary, inasmuch as that by the recent Act of Parliament a very rigid examination for all future chemists and druggists is rendered compulsory, and it is considered that with such an educational status the safety of the public is most effectually provided for; and that, as the said regulations cannot be carried out without inspection, it is felt to be a most unjust and inquisitorial interference with the liberties of a body of tradesmen recognized as almost approaching the medical profession, who are not to be affected by such proposed legislation."

BRADFORD CHEMISTS' ASSOCIATION.

On Wednesday, the 21st ult., a Special General Meeting of all members of the trade was convened to be held in the room of the Society in Salem Street, to consider the "Amended Pharmacy Act." The response to this invitation was only small. The opinion of most of the leading members appeared to be that neither the Bill nor the Regulations which it sought to enforce could be hailed as a blessing conferred upon the trade, and, therefore, could not receive their support; yet it was thought that the fierce opposition and denunciation of some of its opponents was greatly in excess of what it merited, and that a more temperate and conciliatory attitude towards the Government would bring about a more satisfactory result. The following resolutions passed unanimously:—

1st. That this meeting having heard read a Bill entitled "An Act to Amend the Pharmacy Act of 1868," introduced into the House of Lords, and passed through all its stages in about a week, and having considered the same, expressed its strong disapproval of the Bill, and the unseemly haste with which it is being pushed through Parliament.

Proposed by Mr. Cockshott, seconded by Mr. Swaine—
2nd. That a petition to the House of Commons against the passing of the Bill be signed and forwarded for presentation to one of the borough members.

Proposed by Mr. Beanland, seconded by Mr. Pullen—
3rd. That the best thanks of the meeting be given to the President, Mr. Rimmington, for his services in the chair.

BIRMINGHAM.

At a Meeting of the Midland Counties Chemists' Association, held at the Temperance Hall, Birmingham, on June 27th, the following resolution was *unanimously* agreed to:—

Moved by Mr. George Dymond, seconded by Mr. C. J. Arblaster:—

"That the following form of petition to Parliament in reference to the Pharmacy Act now before Parliament, be adopted by this Council, and it is ordered that it be signed by the President and Secretaries and forwarded to Mr. Dixon for presentation."
Carried unanimously.

To the Honourable the Commons of Great Britain and Ireland in Parliament assembled.

The humble petition of the Midland Counties Chemists' Association, as represented by a meeting of the Council of that Association, held in Birmingham, on June 27th, 1871:—

Showeth:

"That, whereas a Bill, entitled 'An Act to Amend the Pharmacy Act, 1868,' is before the House of Commons, which contains provisions for imposing upon chemists and druggists in Great Britain compulsory regulations for the keeping and selling of poisons; and, whereas this subject has already obtained the serious attention of the Council of the Pharmaceutical Society, of the Pharmaceutical Society at large and of its Annual Meeting held last month in London; and, whereas these bodies have, after due deliberation, agreed upon the adoption of certain 'Recommendations' to be observed by chemists in keeping and selling poisons; and as the subject has been by the said Annual Meeting of the Pharmaceutical Society, remitted to the continued attention of its Council during the present year; and whereas, moreover, any legislative compulsory interference on this subject, which applies only to chemists, whilst it exempts the larger body of medical practitioners from its operation, would be partial, ineffective and unjust.

"Your petitioners, therefore, humbly pray that your honourable House will, for the present, suspend any further action in reference to the said Act, until the measures which the Pharmaceutical Society have adopted to attain the end in view, and which they still have under their care, have had a fair and reasonable trial, or until (if legislation be at last necessary) a more just and equal measure is prepared which shall embrace the whole of the dispensers of medicine in the kingdom.

"And your petitioners will ever pray.

"Signed by George Dymond,
"*President of the Association.*
"Joseph Lucas, }
"W. R. Jones, } *Secretaries.*"

A similar petition to Parliament from chemists and druggists was adopted, and is already extensively signed by the chemists of Birmingham and the district.

The Pharmaceutical Journal.

SATURDAY, JULY 1, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACEUTICAL HOLIDAYS.

AMIDST the turmoil of the poison regulation question, it will, doubtless, be pleasant to many a hard-worked pharmacist to look forward to the time when the British Pharmaceutical Conference affords an opportunity for shaking off some of the dust of the shop and meeting together in friendly discussion. It is almost superfluous to remind our readers that the Conference meeting will this year be held in Edinburgh. The place of meeting is the Craigie Hall, St. Andrew's Square, where the President, Mr. W. W. STODDART, F.C.S., F.G.S., will deliver an address, on Tuesday, August 1st, at 10 A.M., prior to the reading and discussion of papers on pharmaceutical subjects during the rest of that day and Wednesday.

The Craigie Hall will be open as a reception room for members, from 9 A.M. to 6 P.M., on Monday, July 31st; Tuesday, August 1st; Wednesday, August 2nd and Thursday, August 3rd.

In addition to the attractions of Edinburgh, due to its situation and as the chief town of North Britain, the objects of interest in the city are numerous. Among these are the Castle, containing the ancient Regalia of Scotland, and commanding from its ramparts a most extensive view; the Chapel and Palace of Holyrood, rich in historical associations; Arthur's Seat, 822 feet high, and the Calton Hill, crowned by the National Monument. The Royal Observatory and Nelson's Pillar afford a prospect of the Frith of Forth and Ochil Mountains, which is not surpassed by any other locality in the world.

In the neighbourhood:—Roslin Castle, Hawthornden and the rare old chapel well merit a visit. Abbotsford, the seat of the late Sir Walter Scott, can be reached by rail in an hour and a half. The Queen's Drive, surrounding Arthur's Seat and Salisbury Craigs, Dalkeith Palace and grounds, new Battle Abbey, Dalhousie Castle, Hopetoun House, Dalmeny Park, and many other places of great interest and beauty, are within easy driving distance. Objects of interest to the geologist, botanist and student of natural history, will be found in abundance. Daily excursions may be had by railway to some of the finest Highland scenery.

The local members propose to give a Conversazione to their visitors, on the evening of Tuesday, 1st of August. It will take place in the Museum of Science and Art, at eight o'clock. A ticket of invitation has been forwarded to each member of the Conference, admitting himself and a lady. The Local Secretary begs that acceptances of the invitation be sent as early as possible.

Edinburgh and its neighbourhood have peculiar attractions for visitors, whether scientific or not. The city itself, especially from its situation, is well worthy of a visit. The whole district, for thirty miles round, is of high interest from the historic and antiquarian point of view; and there is an admirable field for the geologist and for students of natural history generally. As regards the meetings the public buildings in Edinburgh, and especially the University Class Rooms, afford ample accommodation, and from their proximity to each other they are eminently convenient.

It is considered probable that this meeting will be very numerously attended, owing to the facilities now afforded by the several railway and steamboat companies to parties travelling from all parts of Great Britain and the Continent.

The Railway Companies, in terms of an arrangement amongst themselves, will convey members of the British Association from any part of Great Britain to and from Edinburgh with first or second class return tickets, such tickets being available from *Tuesday, the* 1*st day of August*, until and including *Friday, the* 11*th day of August*, being the day after the meeting is concluded. Visitors to the Conference, however, are included in this extension of the usual limits of return tickets, since they would require to reach Edinburgh on Monday, July 31st. For those who may have time for a longer stay *tourists' tickets* to the North and West Highlands, are available for return within one month, with permission to break the journey at Melrose, Edinburgh, Perth, Dunkeld, Blair-Athole, Aberdeen, Inverness, and any other station where the train or steamer stops, either in going or returning.

LEMON AND LIME JUICE.

WE insert in another column a letter from Mr. ROBERT PALMER, relative to the adoption of citrate of potash as "a substitute for the horrible mixture of lemon-juice and rum with which our sailors are now drenched by Act of Parliament." We recur to this subject because it has already given rise to some leading remarks, and because we believe it to be the duty of the chemist to aid the physician in determining the exact value of prophylactic, as well as curative agents.

But we think that Mr. PALMER protests, and attempts to prove, too much. Lemon-juice and rum do *not* make by any means a "horrible mixture," nor do sailors particularly object to be "drenched" with it. According to the evidence of Budd, Parkes, Bryson and others, citric acid *has* antiscorbutic virtues, but inferior to those of lime and lemon-juice. It appears, indeed, that Mr. Palmer's communication includes things new and true, but some things that are true and not new, as well as some that are new and not true.

We have, however, to acknowledge his efforts as far as citrate of potash is concerned, and propose in a future number to lay before our readers the precise kind and amount of evidence (up to the present date) that exists as to the antiscorbutic value of lime and lemon-juice, as well as of all substitutes that have hitherto been proposed, and received a fair practical trial. Chemists then can judge whether the experience of the past will avail them in settling what is still a vexed question—the exact anti-scorbutic principle of lime and lemon-juice. Then, but not till then, shall we be in a position to recommend a substitute.

DR. RICHARDSON ON THE PHARMACOPŒIA.

In an address delivered before the St. Andrew's Medical Graduates' Association by Dr. B. W. Richardson, and recently published, occur the following remarks upon the Pharmacopœia, which may be of interest to our readers:—

"We had for a long time a book of common forms; a Latin book, in Rose, Shamrock, and Thistle editions, full of strange tales,

'Of herbs, plants, flowers, and their true qualities,'

writ in Latin. At last the strongest man in the practical reform of our craft in our time—the Cromwell of physic—condemned the book and its mysteries, and now it floats, in simple English dress, preparing to make its bow and retire altogether. Before I name the book, I must in parenthesis, say who this strong man was. It was the man who, opening the locked doors of hospitals, nailed them open, and who left behind him a work which—though its blasts and its hurricanes are subdued, though its noble Saxon tongue, ringing like the hammer of Thor on an anvil of silver, hath caught the Norman lisp, and though the hand of the poet, born, not made, moves in it no more—is, notwithstanding, under the momentum of his genius, still one of the most powerful class-journals in the worlds. The man I mean was the late Mr. Wakley.

"As for the book which he condemned, and which flourishes in this day as the 'British Pharmacopœia,' though the reform in it is not stout winning, it is a good giving-up of dead weight, and amidst an ocean of discouragement, is a faint but hopeful sign of advancement. It is beyond what it seems. It is leading us to ask whether simplification cannot be carried out further, and whether investigation as to remedies cannot be rendered more precise; it affords scope for the introduction of principles in therapeutics, and, binding us by a more correct nomenclature with advanced chemistry, it connects us closely with one section, at least, of the more accurate sciences."

We are requested, by the Special Committee directing the operations of the Society in reference to the Pharmacy Bill, to state that in addition to the petitions reported as having been presented to the House of Commons, other petitions have been sent up from Barnsley, Newark, Norwich, Weston-super-Mare, Ipswich, Stoke-on-Trent, West Hartlepool, Hereford, Ealing, Flint, Colchester, Basingstoke, Chesterfield, Tamworth, King's Lynn, Denbigh, Truro, Elgin, Windsor, Dorchester, Newbery, Ripon, Worcester, Great Yarmouth, Watford, Belfast, Cirencester, Montrose, Barnet, Berwick-on-Tweed, Chatham and Kent, Darlington, Stamford, Kingston-upon-Hull, Newcastle-under-Lyme, Bridlington, Wrexham, Rugby, Oxford, Folkestone, Leith, Bridport, Horsham, St. Alban's, Whitby, South Shields, Dover, Greenock, Knaresborough, Maidenhead, Wallingford, Thirsk, Bewdley, Selby.

We are informed that out of about two thousand chemists and druggists in the towns named, about eighteen hundred have signed the petitions.

The following *résumé* of the French regulations as to the sale of poisons may, at the present time, be of some interest to our readers:—Extract of decree of October 29, 1846, concerning the sale of poisonous substances. Poisonous substances for use in medicine can only be sold by pharmaciens, and from the prescription of a physician, surgeon, officer of health or licensed veterinary. This prescription ought to be signed, dated, and to detail fully the dose of the said substances, as well as the method of administration of the medicine. The pharmaciens shall copy the said prescriptions in a special register, endorsed and signed by the mayor or commissary of police. These copies ought to be made one after another and without any blank. The pharmaciens shall not return the prescriptions unless stamped with their seal; and after having thereon indicated the day when the substances have been delivered and the number of the copy in the register. The said register shall be preserved at least twenty years, and ought to be produced at every requisition of the authorities. Before delivering the medicinal preparation, the pharmacien shall put on it a label, showing his name and residence, and the internal or external use of the medicine. Arsenic and its compounds cannot be sold, except for medicinal purposes, unless combined with other substances. The quantities delivered, as also the name and residence of the buyers, shall be entered in the special register. The sale and use of arsenic and its compounds are forbidden for dressing wheat, embalming bodies and the destruction of insects. Poisonous substances ought to be always kept by merchants, manufacturers and pharmaciens in a secure place and locked up. The following poisonous substances, according to decree of July 8th, 1850, ought to be always kept in a secure place and locked up:—

Hydrocyanic Acid.
Belladonna Extract and Tincture.
Cantharides, Powder and Extract.
Chloroform.
Hemlock, Extract and Tincture.
Cyanide of Mercury.
Cyanide of Potassium.
Corrosive Sublimate.
Foxglove, Extract and Tincture.
Tartar Emetic.
Henbane, Extract and Tincture.
Tobacco.
Nitrate of Mercury.
Opium and Extract.
Phosphorus.
Ergot.
Thornapple, Extract and Tincture.

THE Bill passed during the last session of the New York Legislature* is severely criticized by the *American Journal of Pharmacy*. That journal states that, as the power of appointing the examiners is vested in the mayor, probably it will not be long before the board consists of politicians rather than of men who have the welfare of pharmacy at heart. There is no provision made for apprentices to learn under the guidance and supervision of others how to make up prescriptions; on the other hand, the salaries to be paid to the members of the examining board are so high that, after the licensing of the pharmacists at present engaged in New York, it is estimated that, if the new applications amount to one hundred annually, the licensing of every so-called drug clerk will cost the city one hundred and fifty dollars. The law is also condemned as ignoring the existence of pharmaceutical educational institutions, and as not being likely to give greater security to the public. It is suggested that if one-third of the money were expended on the New York College of Pharmacy, the facilities for pharmaceutical education would be increased; or if, in lieu of such a grant, the examination and licensing of applicants were entrusted to the College, the duty would be better and more satisfactorily performed.

THE State Medical Association of Mississippi, at their annual meeting held in April last, adopted a resolution inviting the "druggists, pharmaceutists and chemists" of the state of Mississippi to organize a State Pharmaceutical Association, to meet annually at the same time and place that the Medical Association does, and co-operate with it in all measures of mutual interest and importance.

THE Practical and Analytical Laboratory connected with the Philadelphia College of Pharmacy has been again placed by the Board of Trustees under the charge of Professor J. M. MAISCH. With a view of bringing this important feature of pharmaceutical education within the reach of all students, the fee for the coming winter session has been considerably reduced.

* See *ante*, p. 587.

Transactions of the Pharmaceutical Society.

ADJOURNED SPECIAL COUNCIL MEETING.

June 24th, 1871.

MR. A. F. HASELDEN, PRESIDENT, IN THE CHAIR.

Present—Messrs. Bottle, Betty, Brown, Greenish, Hills, Reynolds, Sandford and Williams. Mr. Flux, the Society's Solicitor, was in attendance.

The "Special Committee" appointed to direct the operations of the Society in communicating with the Local Secretaries and members upon the subject of opposing the Bill submitted their Report, and the circulars and forms of petitions which had been sent out under their instructions.

The following Memorial to the Right Hon. W. E. Forster, prepared by this Committee, was ordered to be sent:—

"*To the Right Honourable* W. E. FORSTER, M.P., *Vice-President of the Council.*

"*24th June*, 1871.

"Sir,—The Council of the Pharmaceutical Society beg most respectfully to submit to you some of the reasons which, they trust, will appear sufficient to induce you to withdraw the Pharmacy Bill, at least during the present Session of Parliament.

"1. The almost unanimous protest of the body of about ten thousand chemists affected by the Bill, whose claim to a hearing is certainly great, since the State owes to their voluntary exertions the gradual evolution of an organized system of pharmacy in Great Britain.

"2. The unfairness of the Bill towards the whole body of chemists, in subjecting them to penalties for such merely technical breaches of the regulations for storing poisons as would be constantly inevitable, whilst the still larger body of medical practitioners has a special exemption from the Act secured to it. We would submit that the danger connected with powerful medicines is either, firstly, inherent to the poison, or, secondly, it belongs to the person dealing with it. If the first presumption be accepted, the State should demand from all citizens the same compliance with regulations: to the second supposition we must emphatically object that there are no grounds for fixing this stigma either upon the Society we represent, or upon the general body of chemists and druggists. The unequal action of this Bill is strikingly shown in the case of Glasgow, where there are about sixty chemists and one hundred and twenty open surgeries kept by medical practitioners, and undistinguishable from the shops of the chemists in their appearance and in the business carried on. The deputation from Glasgow which waited upon the Council of the Pharmaceutical Society has most forcibly shown that the Bill would drive from the shops of the chemists to those of the surgeons all that numerous class of poorer customers requiring remedies that this Bill says may only be supplied by the chemist in a 'poison bottle.' A customer is in the habit of frequenting that shop in which all his wants are supplied. The hardship pointed out as affecting Glasgow would also affect, in a greater or less degree, London and many other places.

"3. The Act of 1868 contains a penal clause (Section 26) which gives to the Privy Council the power of removing from the register, and consequently ruining, any chemist who 'is convicted of any offence against this Act.' The adoption of the regulations would render liable to this penalty every chemist in the daily exercise of his calling. We are certain that it was not the intention of Parliament in 1868 that such penalties should be extended so as to cover hundreds of the circumstances which daily surround the chemist.

"4. The essential condition of such regulations as those now demanded is, that their limits be clearly defined. Now the Poison Schedule of the Act of 1868 has no fixed boundary. It comprehends by the frequent use of the term "*and its preparations*" between one and two hundred drugs; and with regard to the less potent of these preparations great diversity of interpretation and practice exists. Were the words taken literally, there is the absurdity of branding as poisons such remedies as cough lozenges. On the other hand, leading members of this Society have declared that (supported by a legal opinion obtained by the Privy Council) they do not regard such a remedy as paregoric elixir to be a poison within the meaning of the Act. The uncertainty of the chemist is shown by the fact that the British Pharmacopœia distinctly classes the above under the preparations of opium. (It contains 2 gr. of opium to each fl. oz.) The schedule of substances called "Poisons" by the Act of 1868 was drawn for the very different purpose of preventing the uncontrolled purchase by the public of substances which might be used recklessly or for illicit purposes.

"5. That the Government does not recognize such regulations and penalties as a matter of State necessity, is shown by further evidence besides the argument that it now only seeks to apply them to chemists whilst exempting the still larger body of medical practitioners. We allude to an Act passed in the last session of Parliament, intituled 'An Act to Regulate the Sale of Poisons in Ireland,' and in this Act no mention whatever is made of regulations for either storing or dispensing poisons.

"6. We must exercise the practical acquaintance with the subject, recognized by Parliament as belonging to our Society, by expressing our serious apprehension that the manner in which the Act proposes to carry out its object is fraught with great danger. The proposal to legalize certain 'poison bottles,' which a body of 10,000 men must use, and which they must explain to the public as being an absolute indication of danger, whilst the medical practitioners of the country will not use this danger-signal, would almost inevitably lead to a series of fatal accidents. We must solemnly place upon the promoters of the Bill this responsibility. Again, in the matter of fixing a particular day on which the circumstances which were legal on the previous day should become illegal and subject to penalty, we submit that hasty destruction of existing arrangements would in many cases follow, and that the gradual process now extending itself is much safer. Had there been any urgency in the case, we should have been prevented using, as we now feel it proper to do, the argument that, in relation to this subject as to religion, morality, public health, and many other questions, penal legislation is the weakest of the agencies that can be used to promote a good object.

"7. We have preferred to consider *the merits* of the question first, reserving until now the necessity alleged to be imposed by the Act of 1868. The feeling exhibited by our members at the present time contrasts with the absence of any objection in 1868 to the permissive power expressed in clause 1. This shows that no compulsory construction of the clause was then recognized by either of the members of this Society, or by the chemists and druggists generally; under any circumstances the latter, and much more numerous body, had no part in any communication which occurred in 1868, and may claim that the case be considered on its merits. We feel deep anxiety as to what would be the result of Parliament imposing upon our body this measure. It would wound deeply the *esprit de corps* which is so valuable in elevating the tone of a body of men with serious responsibility; it would leave the sense of suffering under an unequal and unjust application of control; it would embitter greatly our relations with a large portion of the medical profession, and would be a most unfortunate commencement of our connection with the medical officer of the Privy Council. As bearing upon the question of public health, our body comprises a very large amount of trained knowledge of chemistry available for the further service of the State in many ways in relation to the purity of air, water, sanitary reform, the adulteration of food, etc.

"We now leave our case in your hands, and earnestly trust that you may be satisfied that the Recommendations already issued, emphasized so much as they will have been by the matter coming before Parliament, will justify you in relying upon our disposition to promote the systematic storing and dispensing of powerful remedies, and in withdrawing the present Bill.

"We are, Sir,

"Your most obedient Servants,

"*Signed pursuant to a Resolution of and on behalf of the Council of the Pharmaceutical Society of Graat Britain,* } "A. F. HASELDEN, *President.*"

The subject of the Pharmacy Bill was discussed at some length.

The Council then adjourned until after the interview of the Parliamentary Committee with the Right Hon. W. E. Forster.

On re-assembling, Mr. Flux was requested to draw up a Report of that interview, and it was

Moved by Mr. Hills, seconded by Mr. Sandford—

That the Reports of the interviews held on Monday and this day with the Right Hon. W. E. Forster on the Amended Pharmacy Bill be printed in the Journal after having been submitted to him, and his consent obtained thereto.

For—

Messrs. Haselden, Hills, Sandford and Williams.

Against—

Messrs. Betty, Brown, Greenish and Reynolds.

The numbers being equal, the chairman gave the casting vote in favour of the motion.

Mr. Bottle did not vote.

The Reports are therefore published in pursuance of the above resolution, see page 13.

Moved by Mr. Reynolds, seconded by Mr. Betty—

That the memorial now forwarded to the Right Hon. W. E. Forster be printed, and a copy forwarded on Monday to every Local Secretary, and that a copy be sent to every member of the House of Commons not later than Tuesday.

For—

Messrs. Betty, Brown, Greenish, and Reynolds.

Against—

Mr. Sandford.

Messrs. Bottle, Haselden, Hills and Williams did not vote.

The motion was therefore carried.

The following petition was ordered to be presented:—

To the Honourable the Commons of Great Britain and Ireland, in Parliament assembled,

The humble Petition of the Council of the Pharmaceutical Society of Great Britain,

Showeth,

That whereas a Bill intituled "An Act to Amend the Pharmacy Act, 1868," has been passed through the House of Lords, and is now before your Honourable House, that the said Act contains provisions which will inflict grievous annoyance and injury on chemists and druggists, and that such provisions are in no wise necessary either for the safety of the public, or for the due carrying out of the provisions of the Pharmacy Act, 1868.

Your Petitioners therefore humbly pray that your Honourable House will refuse its sanction to the said Amended Act, or postpone its consideration, to enable evidence to be presented, by which your Petitioners will be able to satisfy your Honourable House that the said Amended Act is unnecessary and unjust.

And your Petitioners will ever pray.

Moved by Mr. Reynolds, seconded by Mr. Greenish, and

Resolved—That the President be authorized to sign the Petition to the House of Commons as now drawn up.

The Petition was forwarded to Mr. Alderman Lusk for presentation.

Deputations to the Right. Hon. W. E. Forster.

Monday, 19th June.

The President, the Vice-President and the Treasurer, accompanied by Messrs. Betty, Sandford and Williams, and the Secretary, waited on the Right Hon. W. E. Forster, Vice-President of the Privy Council, as per appointment, on Monday, June 19th, for the purpose of suggesting amendments in the Pharmacy Bill.

The first question discussed was the extension of the provisions of the Bill to all persons keeping open shop for the sale and dispensing of poisons.

Mr. Forster doubted whether on the part of the the Government, he could introduce such an amendment, but if introduced by an independent member, promised that he would give it his favourable consideration.

The second point was the omission of those words in the Bill which render the failure to obtain the consent of the Privy Council to regulations a ground for the Privy Council at once to frame regulations entirely independent of any consent or co-operation of the Council of the Pharmaceutical Society.

Mr. Forster objected to this course, but received favourably a suggestion that a delay of two months should be allowed to elapse before action could be taken by the Privy Council after notice of non-approval had been given to the Council of the Society.

A second proposition, to append the rules lately approved and recommended by the Pharmaceutical Society as a schedule to the Bill, was made by Mr. Forster.

A clause for enabling the Registrar to keep a more correct register was submitted to Mr. Forster, and had his approval.

Mr. Forster said that the Bill would be read a first time on that day and printed as sent from the House of Lords; it would not be read a second time until Monday the 26th inst.; and he would give the deputation another audience on Saturday next the 24th inst., at one o'clock, when he would be prepared to submit such alterations as he could propose.

Saturday, 24th June.

A deputation consisting of the following members of the Parliamentary Committee, the President, Treasurer, the Messrs. Bottle, Betty, Brown, Greenish, Reynolds, Sandford and Williams, accompanied by the Secretary and the Society's Solicitor, waited on the Right Hon. W. E. Forster on 24th June, as per appointment.

The President explained that since the former attendance of the Parliamentary Committee there had been a Special Meeting of the Council, at which certain resolutions had been passed and that, in accordance with one of the resolutions, a memorial had been prepared by the Council. He also said, that being one of those who waited upon the Right Honourable gentleman on Monday, he hoped that he (Mr. Forster) would favour them with his present views upon the amendments which had been suggested.

The memorial was then handed to Mr. Forster.

Mr. Forster having perused the memorial, and received explanations respecting some of its statements, said that he had expected to hear the provisions of the Bill discussed, and perhaps improvements suggested; and, with a view to the consideration of suggestions, he had arranged for the presence of Mr. Simon, and Mr. Jenkyns from the office of the Government draftsman. He should have been pleased to hear anything which might have been said by those desirous of improvement, but thought that there could not be useful discussion with a body of gentlemen who would only be content with the rejection of the Bill.

Mr. Williams suggested that gentlemen who wished to see the Bill improved were present, and that it was desirable that Mr. Forster should state what he might be prepared to concede.

Mr. Forster said that, whilst he should be happy to go fully into the matter with a deputation in favour of the Bill, and desirous of improving it, he must decline discussing modifications with a deputation committed to opposition.

Mr. Brown pressed Mr. Forster to concede delay in the second reading, and to consider whether public advantage might not result from delay until next session, when probably an improved Bill, satisfactory to the chemists and druggists generally, might be brought in.

Mr. Forster could promise that the Bill should not be read a second time before next Monday week (July 3rd), but could not consent to delay it until next session. He referred to the Act, and remarked that the intention of the Parliament of 1868, that there should be compulsory regulations, was shown by the first clause, and he did not think that the views of the present Parliament would be different. His individual judgment was with the clause, and in his official position he felt it to be a duty to give effect to the Act. He should be prepared to meet the opponents of the Bill if they would raise in Parliament the direct issue whether the legislation of 1868 should be revoked; but in any event, although the period of the year would be in favour of opponents to the measure, he must accept the issue, and, whilst conceding reasonable time, be understood as intending to press for the principle of the Bill.

Mr. Sandford urged Mr. Forster to state the points of concession which he was prepared to make.

Mr. Forster replied that he could not enter upon that course with direct opponents to the measure.

The committee then thanked Mr. Forster for the interview, and withdrew.

EXAMINATION IN LONDON.

June 21st and 23rd, 1871.

Present (21st)—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Garle, Hanbury, Haselden, Ince, Linford and Southall.

Dr. Greenhow was also present on behalf of the Privy Council.

(23rd)—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Garle, Hanbury, Haselden, Ince and Linford.

Ten candidates presented themselves for the Major Examination, and twenty-eight for the Minor; the following twenty-eight passed, and were declared to be duly qualified to be registered:—

MAJOR (as Pharmaceutical Chemists).

*Overton, Charles Arthur	Horncastle.
*Churchill, Henry	Reading.
*Pretty, Charles	Birmingham.
Walker, John Sydenham	Manchester.
Savory, Harry Banting	Painswick.
Wing, Lewis	Torquay.
Lake, Richard	Colchester.
Byles, James Henry	London.

* Passed with honours.

MINOR (as Chemists and Druggists).

	*Rammell, Edward	Crediton.
	*Hughes, James	Swansea.
	*Butcher, Henry	Sheffield.
	*Williams, Jabez Vivian	Ramsgate.
	*Wood, Alexander	New Brentford.
	*Beach, Tom Clarke	Great Malvern.
	Mills, Robert	London.
	Knight, John Tomlinson	Nottingham.
	Holme, William James	Bacup.
Equal.	Baldock, James Thomas	Rochester.
Equal.	Sharp, Alfred Joel	Spalding.
	Bradley, William	Dudley.
Equal.	Watmore, James	Wokingham.
Equal.	Wenham, George Daniel	King's Lynn.
	Tomlin, Albert Roberts	Barnsley.
Equal.	Cooper, William J.	Cockermouth.
Equal.	Goulden, Herbert	London.
	Jones, William Ellis	Barmouth.
	Dunn, Henry	Shipley.
	Rogers, John Maulden	Newport Pagnell.

The above names are arranged in order of merit.

FIRST, OR PRELIMINARY EXAMINATION.

The certificate presented by the undermentioned was received in lieu of this examination.

Haworth, James Bury........Camden Town.

ERRATUM.—Page 996, line 22, *for* Brown, James Macdonald, *read* Brown, John Macdonald.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

June 1st.—Professor FRANKLAND, F.R.S., President, in the chair. The following gentlemen were elected Fellows:—H. Adrian, H. Durham, G. Martineau, E. Neison.

Dr. DEBUS, F.R.S., delivered a lecture on "Ozone." The first who had observed that the passage of electric sparks through oxygen brings about a change in the properties of this gas was Van Marum. The next to take up the subject was Schönbein, in 1840. He ascribed the peculiar odour and the more energetic oxidizing properties of the altered oxygen to a substance which he termed ozone. He also found that ozone may be prepared by many other methods. His experiments, however, led to no positive results as regards the nature of ozone. It was through the researches of Marignac and De la Rive that ozone was shown to be nothing but an allotropic modification of oxygen.

Dr. Debus then discussed the question whether there existed another modification of oxygen called antozone, and answered the proposition negatively; the substance called antozone was only peroxide of hydrogen. The lecturer concluded by calling special attention to one of the characteristic reactions of ozone, viz. the decomposition of potassic iodide, which reaction is differently explained by the various observers. Schönbein has shown that potassic iodide protects free iodine against the action of potassic hydrate. It may be assumed that potassic hydrate and an iodine solution react upon one another thus:—

$$KHO + I_2 = KIO + HI,$$

and then—

$$KHO + HI = KI + H_2O;$$

if now an excess of potassic iodide be added, the potassic hypo-iodide and potassic iodide produce again potassic oxide (which becomes, in its turn, a hydrate) and iodine, and the excess of iodide prevents the action of KHO on the iodine, but not that of the latter on starch.

* Passed with honours.

CALIFORNIA PHARMACEUTICAL SOCIETY.

At the twenty-first Meeting of the California Pharmaceutical Society, recently held in San Francisco, the Constitution and Bye-laws, drawn up with a view to the incorporation of the Society, were read and approved, and the Committee empowered to take active steps to secure that object. The following report of the Executive Committee was also read:—

The Executive Committee of the California Pharmaceutical Society herewith present the Constitution and Bye-laws of the Society, amended with a view to the speedy incorporation of the Society, according to the laws of the State of California.

The Pharmaceutists throughout the country are gradually awakening to the importance of a thorough practical and scientific pharmaceutical education, in order to place the practice of pharmacy where it properly belongs —among the learned professions, a rank already accorded to it in most parts of Europe—and as to further develope this sentiment among our fellow-pharmaceutists was the prime motive in organizing the California Pharmaceutical Society, we regard it the duty and interest of all pharmaceutists to identify themselves with us.

That, in order to elevate the standard of pharmaceutical education in our midst, an institution aiming at the objects expressed in our Constitution is absolutely necessary, we think, all must concede.

The practice of pharmacy has been placed under legislative restriction in most parts of Europe, and, as is well known, sumptuary and restraining laws have been passed recently by the legislatures of various States of the Union; and a regard for our own reputation would seem to require us to prepare and offer a Bill providing for the examination and registration of apothecaries to the Legislature at its next session.

Knowing it to be the will of our organization that we enroll ourselves among the incorporate bodies of the land, that thereby we may strengthen and increase our influence, and provide for our future prosperity; and believing that our action herein is but the prelude to the early establishment of a College of Pharmacy, we offer this report with a sincerely expressed hope that the wishes of our hearts in the matter of the elevation of the character of the pharmaceutical profession in our State may be gradually and effectually accomplished.

(Signed) William Simpson, William Geary, W. T. Wenzell, William E. Mayhew, James G. Steele, *Committee.—Chicago Pharmacist.*

PHILADELPHIA COLLEGE OF PHARMACY.

At the Meeting held May 16th, 1871, Dr. Wilson H. Pile presiding, a paper was read by Professor Maisch, on the Seeds of a Species of Strychnos, brought to New York by a vessel from the East Indies, and exhibited at the meeting in February. He finds them destitute of the alkaloids.

Dr. PILE exhibited four specimens of syrup of iodide of iron, made with glucose, instead of syrup, which is directed in the U. S. Pharmacopœia. His object had been to ascertain whether the effect of such substitution would be to promote the preservation of the iodide without change. Three of the specimens had undergone more change of colour than would have been expected in the officinal syrup, and the other was nearly in the condition that would have been anticipated if prepared by the Pharmacopœia process.

S. MASON M'COLLIN stated that he used glucose as an addition to a variety of syrups, or rather to simple syrup to be used as a basis to medicated or flavoured syrups, with a view to giving it more body, without increasing the tendency to precipitate.

Dr. PILE called attention to the tendency to precipitate, which constitutes one of the difficulties in manipulating with the syrups of the phosphates, and inquired whether it might not be accounted for by impurities in the sugar. Some manufacturers of these preparations had assured him that they gave the preference to "Lovering's Sugar," and found no difficulty with it. T. S. Wiegand, Professor Parrish and others dissented from this view, stating that there was, according to their experience, very little difference between the products of the several sugar refineries that supply our market.

Professor Maisch having observed a crystalline precipitation in mixing solution of morphia with cyanide of potassium, exhibited the results of some of his experiments, and reported that hydrocyanate of morphia is nearly insoluble in water and in an excess of the precipitant, but dissolves readily in diluted mineral acids. The experiments were made with granular cyanide of potassium and with cyanide of ammonium, prepared from hydrocyanic acid and ammonia.

MEETINGS FOR THE ENSUING WEEK.

Tuesday July 4. ......*Society of Biblical Archæology*, at 7.30 P.M.—"On the Flora of Palestine." By B. T. Lowne.

Friday July 7. ....*Royal Botanic Society*, at 4 P.M.—"Economic Botany." By Professor Bentley.

Saturday ......*Royal Botanic Society*, at 3.45 P.M.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

APPOINTMENT.

Dispenser for the Gambia Settlement; must have passed the Minor or Modified Examination of the Pharmaceutical Society. For particulars, see advertisement in the Journal of last week.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Pharmacy Bill.—*June* 22.—Petitions against the Pharmacy Act Amendment Bill were presented from—

Bolton-le-Moors, by Mr. Hick.
Brighton, by Mr. James White.
Bury, by Mr. Philips.
Crewe, by Mr. Tollemache.
Devonport, by Mr. J. D. Lewis.
Dewsbury, by Mr. Serjeant Simon.
Driffield, by Mr. Sykes.
Dundee, by Mr. Armitstead.
Eastwood and Bawtry, by Mr. C. Forster (for the Speaker).
Glasgow, by Mr. Graham.
Halifax and District, by Mr. Stansfeld.
Hampstead, by Lord George Hamilton.
Hyde, by Mr. C. Brooks.
Islington, by Mr. M'Cullagh Torrens.
Leamington, by Mr. John Hardy.
Lee, Lewisham, and Blackheath, by Mr. J. G. Talbot.
Leek, by Sir C. Adderley.
Maidstone, by Sir J. Lubbock.
Nottingham, by Mr. C. Seeley.
Oldham, by Mr. Hibbert.
Richmond, Yorkshire, by Sir Roundell Palmer.
Rochdale, by Mr. B. Potter.
Sittingbourne, by Mr. Pemberton.
Southport, by Mr. Cross.
Stockport, by Mr. Tipping.
Sunderland, by Mr. Candlish.
Wakefield, by Mr. S. Beaumont.

June 23.—Mr. W. M. Torrens gave notice that on the order for the second reading of the Pharmacy Act Amendment Bill on June 26, he should move that it be read a second time that day three months. Petitions against the Bill were presented from—

Bacup, by Mr. Holt.
Bayswater and Kensington, by Sir Henry Hoare.
Beverley and Bridlington, by Mr. Broadley.
Bishop Auckland, by Mr. Pease.
Brigg, Louth, and Barton-on-Humber, by Mr. R. Winn.
Cradley, Lye, and Quarry Bank, by Mr. Lyttelton.
Eastbourne, by Mr. Dodson.
Evesham, by Colonel Bourne.
Kendal, by Mr. W. Lowther.
Liverpool, by Mr. W. Rathbone.
Lytham, by Colonel Wilson-Patten.
North London and elsewhere, by Mr. M'Cullagh Torrens.
Plymouth, by Mr. Morrison.
Reading, by Mr. Benyon.
Scarborough, by Sir H. Johnstone.
Sheffield, by Mr. Hadfield.
Staleybridge, by Mr. Buckley.
Stockton-upon-Tees, by Mr. Dodds.
Swansea, by Mr. Dillwyn.
Todmorden and Selby, by Mr. Fielden.
Warminster, by Lord H. Thynne.
Woolwich and Plumstead, by Sir D. Salomons.

June 26.—The second reading of the Pharmacy Act Amendment Bill was deferred till Thursday, July 6. Petitions against the Bill were presented from—

Ashby-de-la-Zouch, by Lord J. Manners.
Ashton-under-Lyne, by Mr. Mellor.
Bewdley, by Colonel Anson.
Bideford, by Sir S. Northcote.
Blackheath, Lee, and Lewisham, by Mr. Mills.
Burnley, by Mr. R. Shaw.
Buxton, by Lord G. Cavendish.
Carnarvon, by Mr. Jones-Parry.
Clitheroe, by Mr. Assheton.
Council of the Pharmaceutical Society, by Mr. Alderman Lusk.
Durham, by Mr. Henderson.
Gateshead, by Sir William Hutt.
Helensburgh and Dumbarton, by Mr. Bouverie.
Heywood and Eccles, by Mr. A. Egerton.
Kentish Town, by Mr. T. Chambers.
Leeds, by Mr. Baines.
Lincoln, by Mr. Seeley.
Middlesborough, by Mr. Bolckow.
Newport, Isle of Wight, by Mr. C. Clifford.
Pembroke and Pembroke Dock, by Mr. T. Meyrick.
Ramsbottom, by Mr. J. Snowden Henry.
Reading, by Mr. Shaw Lefevre and Colonel Lloyd Lindsay.
Ringwood, by Mr. Cowper-Temple.
Spalding, Sleeford, and Heckington, by Mr. Welby.
Wandsworth, by Mr. Peek.
Whitehaven, by Mr. C. Bentinck.

June 27.—Petitions against the Pharmacy Act Amendment Bill were presented from—

Aylesbury, by Mr. N. de Rothschild.
Bath, by Sir W. Tite.
Barnstaple, by Mr. T. Cave.
Blackburn, by Mr. Hornby.
Boughton, near Faversham, by Mr. G. Milles.
Bradford, by Mr. W. E. Forster.
Canterbury, by Captain Brinckman.
Carlisle, by Sir W. Lawson.
Cleckheaton and Harrogate, by Mr. J. Fielden.
Coventry, by Mr. Eaton.
Derby, by Mr. Bass.
Dewsbury, by Mr. Serjeant Simon.

Dunfermline, by Mr. Campbell.
Forfar, by Mr. Baxter.
Goole, by Mr. Dennison.
Grossington, by Lord F. Cavendish.
Horncastle, by Mr. Chaplin.
Hull, by Mr. Clay.
Kidderminster, by Mr. Lea.
Kilburn, by Viscount Enfield.
Kingston-on-Thames, by Mr. Peek.
Macclesfield, by Mr. Brocklehurst.
Newcastle-on-Tyne, by Mr. Headlam.
Perth, by Mr. Kinnaird.
Peterborough, by Mr. Whalley.
Reading, by Sir F. Goldsmid.
Rochester, by Mr. Wykeham Martin.
Taunton, by Mr. Barclay.
Tewkesbury, by Captain Price.
Tunbridge Wells, by Mr. Dyke.
Wareham, by Mr. G. Sturt.
Winchester, by Mr. W. B. Simonds.

June 28.—Petitions against the Pharmacy Act Amendment Bill were presented from—
Abingdon, by Colonel C. L. Lindsay.
Bridgnorth, by Mr. W. H. Foster.
Bristol, by Mr. Kirkman-Hodgson.
Bury St. Edmund's, by Mr. Hardcastle.
Cardiff, by Colonel Stuart.
Chelmsford, by Lord E. Cecil.
Colne and Haslingden, by Mr. Holt.
Doncaster, by Mr. H. F. Beaumont.
Dorking and Farnham, by Mr. Cubitt.
Gainsborough, by Sir M. Cholmeley.
Greenwich, by Sir D. Salomons.
Gosport, by Lord H. Scott.
Ilfracombe, by Mr. Acland.
Knutsford, by Mr. W. Egerton.
Leominster, by Mr. R. Arkwright.
Liscard, by Mr. Laird.
Lowestoft, by Mr. Corrance.
Ludlow, by Lieut.-Colonel W. Clive.
Market Weighton, by Mr. Sykes.
Northallerton, by Mr. Hutton.
Northampton, by Mr. Gilpin.
Ross, by Sir J. Bailey.
Shaftesbury, by Mr. Glyn.
Stirling, by Mr. Campbell.
Stowmarket, by Colonel Parker.
Sydenham and neighbourhood, by Mr. Mills.
Tunbridge Wells, by Lord Holmesdale.
Walsall, by Mr. C. Forster.

Poisoning by Strychnia in Sweetmeats.

An inquest has been held in Brighton to inquire into the cause of death of Sidney Albert Barker, a boy about four and a half years of age, who died shortly after eating some chocolate creams, purchased at Mr. Maynard's, in West Street, with symptoms that seemed to point to poison as the cause of death. The following are the facts as they appeared in evidence:—

On Monday morning, about nine o'clock, Mr. Charles David Miller bought some chocolate-cream at Mr. Maynard's shop. He gave one of the drops to the deceased, who complained of its being "nasty," and his brother, Mr. Ernest Miller, spat one out as soon as he put it in his mouth. Notwithstanding this, however, Mr. Miller ate several of the drops himself, and shortly afterwards felt very unwell. A feeling of coldness suddenly came over him; he shivered all over, and his limbs became quite rigid. As these feelings recurred to him when he attempted to get from the chair in which he was sitting, a medical man was sent for. Mr. Tuke, surgeon, on his arrival, attributed these symptoms to nervousness, and said there was no harm in the chocolate. Mr. Miller, however, continued to feel very unwell throughout the day. In the afternoon some more of the drops were given to the deceased, who almost directly afterwards was taken violently ill, and cried and screamed in a most alarming manner. Then his feet began to stiffen and his face to become black. He was, thereupon, put into a warm bath with mustard in it, and Mr. Rugg, surgeon, having in the meantime been sent for, this gentleman on arriving, found the child in strong convulsions, and its bowels much distended. Before inquiring the cause, he was told the circumstance of the chocolate-cream, and how the uncle of the child had been taken ill in the morning. His first thought was to remove the poison (for that he supposed it to be) from the stomach, and for that purpose sent for an emetic which he prescribed from the nearest chemist. He at once applied cold vinegar-and-water to the child's head, but before the emetic arrived the child died.

The inquest having been adjourned, that the contents of the stomach might be forwarded to Dr. Letheby for analysis, was resumed on Thursday last.

Mr. Penfold watched the case on behalf of Mr. Maynard, and Mr. Gell on behalf of the father of the deceased.

Dr. Letheby, Professor of Chemistry at the London Hospital, said that he had examined the stomach of the deceased, and found that it presented a perfectly natural appearance, showing no signs of the action of any irritant mineral poison. On examining the brownish fluid smelling of chocolate, which, according to the label, was the contents of the stomach of the deceased, he found in it several pieces of meat partly digested, a small piece of lettuce, and three or four grains of wheat, whole. On analysing this fluid he found it to be perfectly free from mineral poison, but to contain nearly a quarter of a grain of strychnia, which would be quite sufficient to account for death. One of the other parcels he received from Inspector Gibbs contained four kinds of bonbons. The coloured ones, he found on analysis, to contain a preparation of alum and cochineal, but no poison. The white ones, or, at least, the one he analysed, contained strychnia. The third parcel contained two kinds of chocolate creams, rose-pink and white, but they were quite free from poison. The colouring matter, though containing cochineal, was prepared rather differently.

By the Coroner.—Strychnia would not be used in colouring sweetmeats, nor in flavouring them, for it is excessively bitter. It is used extensively in the preparation of vermin killers. The symptoms of the deceased, as shown by the evidence, are precisely those which would attend poisoning by strychnia, and there can be no doubt that that was the cause of death.

Mr. Tuke, surgeon, in answer to a question, said that he had given some of the chocolate to a dog, but it seemed to have no ill effect.

Miss Christiana Edmunds said that in September last she bought some chocolate creams at Mr. Maynard's establishment. On that occasion she ate two of them, and, about an hour afterwards, was seized with violent internal pains, and a burning in the throat, which lasted twenty minutes. She did not notice any unusual taste when eating them. On taking some brandy she became worse, and then took some castor-oil, after which she recovered. In March last, she tried some creams again, and a friend who was with her also tasted some of them. They had a strange nauseous metallic taste, and witness had no sooner swallowed a portion of one than she was seized as before, but more violently, and in a slightly different way. There was the same burning in the throat, and a feeling of lightness in that region. The saliva kept flowing into the mouth, and she was seized with a trembling all over, and felt an indescribable sensation. Her face also looked livid. She again took brandy-and-water with the same effect as before, and then trying the castor-oil, she gradually recovered. Her friend was affected in the same way, and took a glass of wine, which made her very sick, and she then also recovered. After the witness had got well, she noticed that her taste had gone, and it did not return for some little time. On the same day she took back the remainder of the chocolate-creams to Mr. Maynard, and told him of what had occurred. He assured her that she was mistaken in supposing that it was the chocolate-creams which had affected her in the way described. Some more were brought and tasted, but they seemed all right. Mrs. Maynard also tasted one of those which the witness had originally bought, and found that there was nothing the matter with it. Mr. Maynard told her he was much obliged to her for coming, and he would communicate with his French agents. He also said that he should be willing for her to have any analysis made that she desired. As she did not feel satisfied she went from Mr. Maynard's to Mr. Schweitzer's, and after telling him the circumstances, asked him to make an analysis. He treated the matter lightly at first, thinking her nervous and fanciful, but, after having tasted one of the creams, he thought differently. He afterwards forwarded her the following result of his analysis:—

"The cream cocoa consists of small, irregular, round cakes, filled with a soft white sugar composition. After examination, it was found that this white composition of some of these cakes, or balls, had a distinct metallic taste, whilst others were perfectly free from it. This metallic-tasting sugar composition, when washed out of the cocoa enclosure, gave, when filtered, a clear colourless solution of a sweet but slightly metallic taste; it had also a faint reaction on litmus paper. When somewhat concentrated by evaporation, it gave white flocculent precipitates with lime-water and with carbonated alkalies, the precipitate being soluble in excess of potash or ammonia. The precipitate produced by sulphuret of ammonium had also a white colour. Chlorine and sulphuric acid were only present as traces. The metal with which the so-called cream of some of the cream-cocoa balls is impregnated is, in fact, zinc, in combination with a vegetable or organic acid. It appears that this cream must be prepared in zinc vessels, where, when left long in contact and acid, those portions which are in contact with the sides of the vessel become impregnated with it, and when scraped off and introduced in the cocoa coating it, imparts to them a highly poisonous character."

In answer to Mr. Penfold, Miss Edmunds stated that she did not communicate the result of the analysis to Mr. Maynard, as he seemed so sceptical and prejudiced about it.

Mr. Julius Schweitzer, analytical chemist, King's Road, was then called, and stated that the above was the result of his analysis. In answer to the Coroner, he said that the metallic poison he found in the creams was an entirely different substance from the strychnia which Dr. Letheby found in those he had examined. In answer to Mr. Penfold, this witness said that he did not take any steps to have the result of his analysis communicated to Mr. Maynard.

Mr. Penfold then asked that Maynard, and one or two of his assistants might be called to speak to the circumstances under which the chocolate was received and sold in his establishment.

Mr. Maynard accordingly stated that he was a confectioner at 39, 40, and 41, West Street. After Miss Edmunds had complained of the chocolate-creams he caused a thorough investigation to be made, and he and his wife and Miss Page, one of the assistants, tasted a great deal of the stock, and could find nothing the matter. He was always particular to make a thorough investigation if ever a complaint was made. He had never manufactured any chocolate-creams himself, but always obtained them wholesale. Since February last he had obtained all his French sorts from a wholesale dealer in London; and he was positive that there was none of the previous stock now in the shop, for owing to the war they had been completely sold out about a fortnight before he obtained his supply from the new source. When the present stock was received in February it was handed over to Miss Page, and it would be proved that it was from some of these that Mr. Miller was supplied with the creams, which he gave to the deceased. When he spoke as though he had received complaints previously he meant such as of the sweetmeats being flavoured with the wrong substance. Miss Edmunds' complaint was the first of that character that he had received. He had a young family, and his youngest boy was in the habit of continually eating these very chocolate-creams. He had never been troubled with rats nor with mice in the shop, as he kept a cat for the purpose of destroying them. About a month ago some phosphoric paste was put in a pot-room, quite away from the shop, and on a different story, where the cat could not get.

The Coroner remarked that it was evident that phosphoric paste had nothing to do with the strychnia, and that Mr. Maynard was more fortunate than the chocolate manufacturers in France, for there they found that nothing but sheet-iron would keep the rats out.

By Mr. Gell.—When we found, after Miss Edmunds' complaint, that there was nothing the matter with the rest of the stock, and not receiving any communication from her, we thought it was all fancy, and did not have any analysis made. The boxes of chocolate-creams that I have in my shop with the "Cadbury" label are English. The cakes are smaller, and in my shop the two sorts are kept entirely distinct.

Miss Kate Page, assistant to Mr. Maynard, was then called, and said that the French chocolate department was under her management, and after the goods were received from London they were placed in cases in the store-room. The average sale of French chocolate-creams was about four pounds a week. The English sort is made up in smaller cakes, and is all white, the pink colour being confined to the French. She could speak positively to all the glasses being empty before the fresh stock was received in February, because they cleared them all out for a gentleman.

By the Coroner.—I cannot suggest any way in which the strychnine could have got into the chocolate while it was on Mr. Maynard's premises, for no one had anything to do with it but myself.

Annie Meadows, the assistant who sold the creams to Mr. Miller, said that she took them out of the case which the last witness had filled. She asserted that those she gave to Mr. Miller were all white, but the Coroner stated that that gentleman had said that Mr. Maynard did not sell any with an ornament on the top, like some which it was stated that Mr. Miller had produced on the last occasion.

Mr. Ware, the manufacturer of these chocolate-creams, said that he had been engaged in business since 1839, and had never had any complaint of this sort made before, though they had made hundreds of tons of the chocolate-creams. He then described the process of manufacture. The white or creamy part, he said, was pure sugar boiled down to a certain pitch, and then treated with cream of tartar to "kill the grain" of the sugar. The colouring-matter in the pink kinds was cochineal or carmine, and the flavour was imported by vanilla, otto of roses, or liqueurs. The chocolate of their manufacture was called French because they used French machinery. He admitted that they were troubled with rats, but not to any great extent. They used dogs, traps, and poison to exterminate them, but as the workmen were paid so much for each one they destroyed, he could not say what sort of poison they used. He remembered some paste being spread on bread-and-butter. All the mixing required in the chocolate manufacture was done on marble slabs.

The Coroner then summed up. He said that as to the cause of death there could be no doubt, for sufficient strychnia had been found in the stomach to kill a child of that age, and the quantity found in the stomach after death was frequently but a fraction of the quantity that had been absorbed into the system. As to the way in which the strychnine was administered, that also was perfectly clear. It must have been by means of the chocolate-creams, but how it got into them could only be a matter of conjecture, and the most reasonable hypothesis was that it was through some misadventure with the vermin poison. But how that got there, there was no evidence to show. They would also have to consider whether any one had been guilty of criminal negligence. The fact of the manufacturer having been established in business thirty-two years, and never having had a complaint previously, was sufficient to show the manner in which his business was conducted, and, therefore, to exculpate him. Mr. Maynard had taken every reasonable precaution, after Miss Edmunds had complained to him; and though it was certainly unfortunate that neither she nor Mr. Schweitzer had thought of communicating the result of the analysis to him, yet, strange to say, the poison discovered on that occasion was evidently quite different from that which had caused the death of the deceased, and must have found its way in a different way. He, therefore, recommended them to find a verdict in accordance with the medical evidence as to the cause of death, and stating that there was no evidence to show how the strychnine got into the chocolate.

The Foreman of the Jury said that they fully agreed with the Coroner's remarks, but would wish to add a suggestion to their verdict, that great care should be taken in using vermin poison at the place of manufacture.

Mr. Penfold wished to state that Mr. Maynard would at once destroy the whole of his present stock of French chocolate.—*Brighton Daily News.*

Suicide by Phosphorous Vermin Killer.

An inquest has been held at Tweedmouth upon the body of Jane Weatherhead. It appeared that the deceased, having had some little difference with her husband, left her home and went to stay two or three days with some friends. Upon returning home her husband noticed that her lips, teeth and tongue were black, and asked her what was the matter. She replied that she had taken poison at Kelso two days previously, in the form of vermin killer. Medical assistance was obtained, but she died the next day.

Dr. Brown said that he found the deceased in a state of collapse, pulseless and breathing heavily; her eyeballs were dilated and she was almost unconscious. He tried to get her to swallow a little milk but she could not. He examined some of her vomit: it was of a dark coffee colour, and had the appearance of containing some undigested blood. He was told that deceased had taken some "vermin destroyer," and that it was a paste. From the appearance and symptoms he was of opinion that the deceased died through poisoning by phosphorus. He considered the case hopeless from the first.

The jury returned that the deceased died from the effects of phosphorus taken while in a state of insanity.

Adulteration of Bread with Alum.

At the City Police Court, Manchester, charges were recently brought against two bakers of having adulterated bread by the admixture of alum. Loaves of bread, which had been purchased at the shops of defendants, were submitted to analysis by Professor Roscoe, who deposed that he had found in the different samples 13, 12, and 4 grains of alum to the pound respectively. In one case it was submitted that in order to convict it must be proved that the defendant was cognizant of the presence of alum in the flour. The magistrate, however, decided that it was the duty of the baker to take care that the flour had no alum in it. A fine of £5 was inflicted in each case.

Review.

Contributions towards the Materia Medica and Natural History of China, for the use of Medical Missionaries and Native Medical Students. By Frederick Porter Smith, M.B. London, Medical Missionary in Central China.—Shanghai: American Presbyterian Mission Press.—London: Trübner and Co., 60, Paternoster Row. 1871. Pp. 237.

This work is the result of the leisure moments of two years spent by the author at the great trading city of Hankow on the banks of the Yang-tse-kiang, some hundreds of miles from the sea. It forms a neatly printed volume in which are arranged in alphabetical order the names either in English or in Latin of a variety of substances, most of which are either found in the drug shops of the Chinese or in the dispensaries attached to the Mission Hospitals. Each name is followed by a Chinese equivalent expressed in native characters. As most of the chemical substances employed in European medicine have no Chinese names, and as the sound of Latin or English words is often inexpressible by Chinese characters, special names framed according to Chinese ideas have been invented. Thus Iodine is termed *Hai-tien* i. e. *Sea-indigo;* Sulphuric acid, *Liu-hwang-yu* i. e. *Sulphur-oil;* Lunar caustic, *Yin-siau* i. e. *Silver-nitre.* Even Chlorodyne is put into Chinese as *Poh-ho-yoh*, literally *Peppermint-medicine.*

Following the name are remarks descriptive of the history and uses of each article. As a specimen we may quote the following:

> "**Sal Ammoniac.**—*Nau-sha, Nung-sha, Peh-ting-*
> "*sha.*—This saline substance, the chloride of ammonium
> "of chemists, is brought from Lan-chau-fu and Ning-
> "hia in Kan-suh. The country of the Tih, or Si-jung,
> "and Turfan formerly yielded it. The volcanic moun-
> "tain of Peh-ting in Turfan is said to have yielded some
> "ammoniacal salt from fissures in its sides, and hence
> "the name *Peh-ting-sha*, more correctly given perhaps to
> "volcanic ammonia. The Chinese name *Nau-sha* is very
> "like the Hindustani names *Naushadar* and *Nausadar*,
> "given to thick, fibrous, translucent cakes of this crude
> "salt of ammonia obtained in India from the unburnt
> "extremity of brick-kilns in which the manure of camels
> "etc. is used as fuel. (Dr. Waring's Ph. of India, p. 309.)
> "Keferstein affirms that both carbonate and muriate of
> "ammonia are found in China, but the dirty-white, rough,
> "deliquescent salt commonly sold under this name is
> "nothing but sulphate of soda, or common salt. Nitre
> "(soda-nitrate) and borax are also confounded with it.
> "It is used as a flux or solder, or is said to be so em-
> "ployed. Whilst the salt is said to be deleterious, it is
> "also said to be used in curing meat, or as a condiment.
> "It is mainly used as a solvent for opacities of the
> "cornea, for which the sulphate of soda acts almost as
> "well. It acts as a sedative, resolvent, deobstruent,
> "pectoral and mild escharotic, in Chinese estimation.
> "They use it in veterinary practice. Some of the
> "samples contain iron, and resemble the *Kala Nimuk*
> "of India."

Several of the substances used in Chinese medicine described some years ago in the pages of this journal are further illustrated by the researches of Dr. Porter Smith. Thus the seeds called *Fe-tsaou-tow** are referred by him to *Acacia concinna* [DC.], with the information that the pods containing them are used instead of soap in the washing of clothes, but from their strong smell are not allowed in the public baths. The root known as *Tsing-mŭh-heang* noticed in one of the papers referred to,† is stated by our author to be that of *Aristolochia contorta* [Bunge], but he does not say how this point was settled, or give any particulars as to the cultivation or collection of the plant. By the *Trade Report of Ningpo*

---

* Ph. J. III. (1862) 8. † Ph. J. III. (1862) 264.

for the year 1868,* we learn however from Mr. Bowra, the Acting Commissioner of Customs, that this drug is an esteemed remedy in rheumatism, and that it is exported from Ningpo to the value of about £26,000 annually.

Concerning *Arrowroot*, our author remarks—"The ordinary native farina called by this generic name "amongst foreigners, is made by grating the root of the "Lotus or *Nelumbium speciosum*, grinding it to a coarse "powder, and levigating it in the ordinary way. . . . "The product is a reddish-white, glistening, unctuous "powder, making a very tenacious jelly of a dark colour. "It answers all the purposes of the best arrowroot, and "is of great value in the treatment of diarrhœa and "dysentery"—but he adds that it is so frequently adulterated with "leguminous farina," that most families endeavour to make it for themselves. No starch appears to be extracted from *Sagittaria*.†

It would have added much to the scientific value and interest of Dr. Porter Smith's work had his statements been a little more *personal*. One is constantly tempted to ask—How did you make out this? As an example,—Common camphor our author asserts is produced in the provinces of Fuhkien and Canton. But on what evidence was this determined? The official *Reports on Trade* published by the Inspector General of Customs‡ show no camphor as shipped from any one of the twelve Treaty Ports of Continental China, but only from the island of Formosa. Dr. Smith then adds that *Borneo Camphor* "is said to come from Chang chau fu in Fuh-"kien, and the tree yielding it, the *Dryobalanops Cam-"phora*, is described as growing in Canton province." We need hardly say that such statements as these are loose and vague, and quite unworthy an important book of reference.

The assertion that the rhizomes of *Iris Florentina*, (a plant not known to exist eastward of the Mediterranean region) "are met with all over China," and a similar remark regarding *Oxalis Acetosella* indicate a want of exactness in discriminating drugs and plants that is calculated to impair confidence in other statements.

We must also raise a protest against the omission of authorities for botanical names which are thus involved in considerable doubt. What plants are *Agave chinensis*, *Smilax chinensis*, *Amomum amarum*, or *Salvia multiorhiza*?

But even with the defects which we have thought it right to notice and which we trust the author will avoid in a future edition, we gladly admit that Dr. Smith's *Contributions* contain a large amount of interesting and useful matter which it must have required no small amount of diligence to collect and arrange. The book is superior to Debeaux's *Essai sur la Pharmacie et la Matière Médicale des Chinois* (Paris, 1865) in that it gives the Chinese characters as well as their sounds expressed in Roman letters, and is besides far more copious. It promises also to be of considerable utility to young Chinese who may study European medicine.

[228.]—SYRUPUS TONICUS.—It may interest Mr. Symes to hear that this syrup was by no means introduced here from Birkenhead, but was first prescribed in January, 1866, by Dr. Crompton, at whose request I prepared it, and who (for reasons stated in his letter here enclosed) called it tonic syrup, of which title Dr. Crompton was certainly the originator.—James Woolley, *Manchester*.

[*** In the letter which has been forwarded to us, Dr. Crompton says:—"I have to observe respecting the imputation conveyed in the note of Mr. Symes, of Birkenhead, that I gave you the formula for syr. ferri et quinæ et strychn. phosph. in the year 1865, and that I at first prescribed it under that title; but, finding it too long, and to be objectionable by containing the word 'strychnia,' I began to prescribe it as 'syrupus tonicus' in 1866, under which name you introduced it to the profession by a printed circular."—Ed. Pharm. Journ.]

[264.]—DISPENSING.—Having just received the undermentioned prescriptions to dispense, I should feel obliged by being informed in the Journal the best way to dispense them.—Jno. Smith.

R. Tinct. Tolu. ʒiss
Tinct. Scillæ ʒj
Syrupi ʒvj
Aq. Cinnam. ad ℥vj.
M. Take a sixth part three times a day.

R. Kreasoti gtt. iij
Zinci Oxydi gr. iij
Mist. Acaciæ q. s.
Mitte xxiv.
M. ft. pil. Take one three times a day with meals. Silver, and send in bottle.

[265.]—DISPENSING.—I received a few weeks ago the following prescription to dispense (a photograph of which I enclose):—

R. Iodi ʒss
Lin. Camphoræ comp.,
Lin. Saponis comp., ana ℥ij.
M. ft. Linimentum pectore infricandum.

At first sight, it may appear that no particular caution is necessary as to the manner in which the ingredients should be brought together, but such is not the case. If mixed in the same order in which they are written, (in many instances this is likely to be the case,) a black precipitate will be thrown down, consisting of iodide of nitrogen, a highly explosive compound, produced by the reaction of the ammonia contained in the lin. camph. co. with the iodine.

Foreseeing the result likely to ensue, I dissolved the iodine in the lin. saponis, and then added the lin. camph. co.: no precipitate was formed. I then, by way of experiment, mixed a small quantity in the reverse order (that in which they were written); a precipitate was immediately produced, which, upon drying and being touched, exploded with a very loud report. I may add that, in whatever order the ingredients are mixed, the liniment speedily decomposes, losing in a day or two nearly all its free iodine.

I have not come across a prescription of the kind before, so have sent it, thinking that it might perhaps be of use to others.—E. Skipper, *Islington*.

Lemon and Lime Juice.

Sir,—In reference to your article on lime and lemon juice, I may mention that some time since my attention was drawn to the subject, with the idea of finding a substitute for the horrible mixture of lemon juice and rum with which our sailors are now drenched by Act of Parliament.

As there is no virtue in citric acid, it struck me that, perhaps, the value of lemon juice as a prophylactic was due to the potash it contains in combination with an organic acid, and that citrate of potash would answer every purpose. I was further confirmed in this view by the writings of Dr. Garrod, and some experiments made with Mr. Deane, of Clapham, upon the salting of meat. From an analysis by Professor Attfield of some beef broth before and after salting, it appeared that the meat lost nearly 50 per cent. of its potash by the process, and that as the soda salt went in the potash salts ran out; this deficiency of potash, we thought, might probably be the cause of scurvy. Following up this idea, I then had some citrate of potash prepared, and through the interest of the Board of Trade some experiments have been made at the "Seamen's Hospital" to test its value.

These experiments have now been carried on for about twelve months, and through the kindness of Mr. Harry Leach, I have obtained a report of the result. Owing to the singularly few cases admitted to the Hospital during the past year, the trials have not been so numerous as we could have wished; still, in all cases, it has been found equally efficacious as the juice; patients treated with citrate entering and leaving the hospital on the same day as those treated with lemon juice. It is true that too much stress must not be laid on these experiments, as there is some doubt as to which does most to promote a cure, the lemon juice or the extra good diet.

I must here leave the matter, as I have no means of testing its value as a prophylactic, but I think it well worth a trial; and if some large shipowner would take it up and try one against the other during a lengthened voyage, the case might be at once decided; and if the citrate should answer the purpose, then the "lemon juice and rum" might be done away with for ever.

This question also involves one as to the use of light wines, such as claret and hock, in gout, rheumatism, etc. May not their virtues be due to the bitartrate of potash they contain?

35, Ovington Square. Robert Palmer.

Poison Regulations.

Sir,—What a terrible fuss the people are making in the Journal about the poison regulations!

I think there is no great objection to those proposed by the Council, beyond the dislike of all interference common to all Englishmen; also, that some precautions are necessary. We all know that twenty years ago in many establishments no precautions whatever were taken; for instance, in the one in which I was apprenticed in London.

Fifteen or sixteen years ago it was held by many (including ourselves), that the greatest safeguard was in sufficient education and attention to what one was about and the use of one's senses. Before I left England, however, poison cupboards were coming into vogue.

In my dispensary I adopt a plan which I have not seen mentioned by any one. It is very simple, and is this:—Poisons that I am afraid of, such as strychnia, arsenic and hyd. bichlor., acetum canth. fortiss. and iodine paint, I put behind the ordinary row of bottles, so that to get at them I have to take down a bottle or two in front. In this manner the space behind the bottles becomes the "poison cupboard," and the front row of bottles the door. I think the plan gets rid, to a certain extent, of the difficulty I have lately seen mentioned, viz. that if all the poisons had to be fetched in as wanted, the risk of accidents from accumulations on the counter would be greater than if the poisons were kept on the shelves, as the dispenser might wait for a spare moment to put his poisons back into their cupboard; whereas, in my plan, they can be (as they should be always) put away directly they are done with. Kaffraria.

King William's Town, April 28th, 1871.

New Pharmacy Bill.

Sir,—The Hull petition against the "new Pharmacy Bill" is signed by eighty-nine chemists in business, only one refusal having been met with. The smaller towns in East Yorkshire are moving, and every place of importance will have its petition. Our county and borough members are with us, and the trade is becoming thoroughly roused. During forty-five years I have been connected with the business, I have never seen anything like it. Lancashire and Yorkshire are sound on the matter, and the white and red rose are twined together to defeat, if possible, this unnecessary and impracticable Bill.

The wholesale case of poisoning at Bradford, referred to by the Right Hon. Mr. Forster, occurred in the "dark ages," thirteen years ago, the arsenic having been purchased at the shop of general dealer and druggist in a neighbouring village during the absence of the master. In that case, the one element necessary to have avoided the accident was education, which, under the Act of 1868, is now compulsory; and it is hard that just when we in the provinces are beginning to realize the necessity of education, and active steps are being taken to found lectures, classes, etc., we are suddenly called from our profitable and peaceful labours to take up arms in defence of our common liberties.

I do not hesitate saying that a heavy blow and sore discouragement have been inflicted on technical education by this uncalled-for attempt at penal and restrictive legislation, to be followed, no doubt, by other and more severe Acts.

As one of the founders, and for twenty years a local secretary of the Pharmaceutical Society, I have always looked upon it as a great educational institution, and, much as I regret the failure of the Council to understand the difference between town and country trade, I believe a considerable measure of success has attended their efforts to elevate the trade, and to impress upon us a due sense of our responsibility. If, however, the present Bill should pass, the Society would become little more than an institution under the coercive action of the Privy Council, or, rather, its restless medical officer, for prying into, and attempting to regulate all the petty details of ten thousand widely-differing businesses; and I can hardly conceive that any man, having a proper feeling of self-respect, or a due regard to his independence, could in such case consent to sit at the Council Board.

No case for parliamentary interference has been made out; and if danger to the public in the dispensing and storing of poisons does exist, it is far less likely to be in the open shop of either the chemist or the surgeon than in places closed to the public eye. In this town, on a careful estimate, it appears that not more than one-eighth of the medicine supplied is dispensed by chemists, and I have little doubt this is a fair specimen of other towns (perhaps London excepted). Can anything more strongly show the inutility and onesidedness of the proposed Bill? Looking at the serious liability now resting on dispensers of medicine, we may well ask to be let alone. Neither surgeon nor chemist needs an Act of Parliament to sharpen his sense of responsibility in dealing with poisons. In the words of the late Jacob Bell (referring to the Bradford case), "With persons acquainted with the nature and properties of poisons, and duly impressed with their responsibility as vendors of such substances, no stronger motive for caution could exist than the dread of a verdict of manslaughter or absolute ruin as the probable result of a fatal accident arising from negligence on their part."

Hull, June 28th, 1871. James Baynes.

Ice Cream Soda.—We think the doubt would still obtain since the preparation would be used more as a beverage than as a medicine.

T. Hughes.—The remarks contained in our correspondent's letter are open to be regarded as personal reflections. We think it advisable that they should not be published.

MATCHES.

BY B. S. PROCTOR.

O Lucifer, how art thou fallen!
Only one penny per box!

The history of the means of getting a light is full of interest in whatever aspect it be viewed; perhaps more interesting to pharmacists than to ordinary mortals, seeing how intimately each step in advance is associated with the progress of chemical and physical discovery; how much the match trade of the last forty years has been connected with the trade of the chemist and the part which has been taken in the development of the same by men well known amongst us. Leaving to our contemporaries the treatment of this subject in its commercial and mechanical aspects, we propose to sketch briefly the chemical history of the art of kindling a flame, from the time when old women were given to making matches to the present day, when the lads and lasses have a good deal of the work in their own hands.

When the first fire was lighted, and who lit it, are questions over which physics and divinity might quarrel without coming to a conclusion; but looking to nations (if our modesty will permit us) which are too young in civilization to wear any clothes, we commonly hear of their fires being ignited by rubbing two dry sticks together till the heat of friction produced fire. The mode of rubbing which is capable of producing sufficient of that "mode of motion" which is known as heat, is difficult of acquirement; and though most of us have tried the experiment in our school days, he was thought very successful who could produce smoke enough to make his eyes water; it is doubtful whether success might have rewarded our efforts, even had we attended to Pliny's recommendation, "rub the wood of the ivy with that of the laurel," so much do we lose the arts of former times when modern inventions enable us to attain our ends with less labour. These dry frictions were only slowly displaced by the use of the flint and steel, which depend upon the same physical principle. A small particle of a hard metal being struck off from the mass by the edge of a stone harder than itself, the particle was always hot, frequently hot enough to enter into active combustion; this, however, produced a short-lived spark, which was only available if received upon some substance very readily ignited and of small conducting power, the material most approved for this purpose being tinder, a charcoal produced by the imperfect combustion of old linen. When the young spark was well received he seldom failed to kindle a match—the matches for this purpose being slips of wood, ten times as large as the lucifers of the present day, pointed at one or both ends and dipped in sulphur. The tinder-box, with its flint and steel, though a great advance upon the friction woods of the early ages, was often troublesome, especially in damp weather, when the tinder absorbed moisture and was slow to ignite. Substitutes for it were constantly sought, but for a century and a half the numerous inventions failed to displace the tinder-box from its post on the kitchen mantelshelf.

Phosphorus, which was discovered about two hundred years ago, kindled the hopes of the fire-seekers, but for a long time it did not kindle much else, for it was very expensive and very dangerous to handle. So lately as fifty years ago nothing else was known in practice but flint and steel, phosphorus matches not being introduced commercially till 1834, and being prohibited in several of the German States on account of their danger up to the year 1840; but during the time phosphorus was in abeyance, much was done with other materials.

Doebereiner, and his wonderful lamp, may claim our first notice. The lamp consisted of a bell-glass immersed in sulphuric acid, and having a piece of zinc suspended in it, so that it generated hydrogen, until the accumulated gas having displaced the acid stopped further action. The bell was fitted with a cock and a piece of spongy platinum, the latter being usually attached to a little piece of mechanism, by which it was brought in front of the cock at the moment the gas was turned on; the gas was thus ignited, and in turn lighted a candle placed in front of it.

Doebereiner's lamp stands quite apart from the other fire-producing contrivances. It depends upon the power possessed in a small degree by many bodies, but in an eminent degree by platinum, of so condensing certain gases upon its surface as to enable them to exercise their chemical affinities much more energetically than in the free or uncondensed state, and depends upon this property being so much exalted by the reduction of the platinum to a spongy condition, that it becomes incandescent when exposed to a mixture of hydrogen and air.

The pyrophori, which were made by heating tartrate of lead, or a mixture of potash, alum and organic matter, in close vessels till they ceased to give off inflammable gases, depended also for their fire generation upon a finely divided metal mixed with carbon; but in this case the metal had not a mechanical but a chemical affinity for oxygen, and as soon as exposed to the air the absorption of oxygen was so rapid as to produce a smouldering combustion.

Phosphorus bottles, which were in vogue during the early days of phosphorus, were too dangerous, both in their production and use, to be much more than philosophical toys. They were made by melting together phosphorus and sulphur in a bottle (which it is said was sometimes blown to pieces in the operation), the sulphide of phosphorus thus produced being readily ignited by friction. The light was obtained by dipping a splinter of wood into the compound, and thus lifting out sufficient to produce the desired fire by rubbing upon any convenient surface; or a bottle, when lined with phosphorus alone, or mixed with one-fourth of wax, was capable of igniting a common sulphur match, if rubbed upon its inner surface.

(To be continued.)

British Spirits.—An annual return shows that in the year 1870 30,220,268 gallons of proof spirits were distilled in the United Kingdom: 7,479,422 gallons in England, 14,483,744 gallons in Scotland (nearly half the production of the United Kingdom), and 8,257,102 gallons in Ireland. Duty was paid in the year on 23,452,242 gallons, amounting, at 10*s.* per gallon, to £11,726,120. The consumption of British spirits in the year is stated at 22,616,490 gallons, viz. 11,940,083 gallons in England, 5,501,987 gallons in Scotland, 5,170,700 gallons in Ireland. 1,633,219 gallons were removed in the year from Ireland to England and Scotland, and no less than 4,258,097 gallons from Scotland to England and Ireland; 125,377 gallons from England to Scotland and Ireland. At the end of the year there were 16,941,149 gallons of British spirits in bonded stores in the United Kingdom ready to supply thirsty souls in 1871.—*Times.*

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Iodum.—[§ A non-metallic element, obtained principally from the ashes of sea-weeds.] I = 127. By the incineration of sea-weeds a semi-fused saline ash is obtained called 'kelp.' This is lixiviated with water, and the solution so obtained concentrated till, by alternate boiling and cooling, the crystallizable salts, potassic and sodic sulphate and chloride, are almost completely separated. The mother liquors are then mixed with sulphuric acid, whereby the carbonates and sulphides present are decomposed, and the mixture is then distilled by a very gentle heat with regulated quantities of black oxide of manganese.

$$2\,NaI + MnO_2 + 3\,H_2SO_4$$
$$= 2\,NaHSO_4 + MnSO_4 + 2\,H_2O + I_2$$

The iodine is purified by careful resublimation.

[§ In laminar crystals of a peculiar odour, dark colour and metallic lustre, which, when heated, yield a beautiful violet-coloured vapour, very sparingly soluble in water, but freely dissolved by alcohol, by ether and by a solution of iodide of potassium. The aqueous solution strikes a deep blue colour with starch.] The colour is destroyed by heat, and therefore cold solutions must be employed for this test. Iodine is also freely soluble in bisulphide of carbon and in benzol, minute quantities communicating to either of these liquids a beautiful violet tint, upon the production of which another very good test for the recognition of iodine and iodides is founded. For a comparison of the properties of chlorine, bromine and iodine, see article Bromum, p. 526, Vol. I. n.s. Iodine stands a little apart from the other two in possessing less energetic affinities, so that its compounds are more readily decomposed, and it exerts no bleaching action upon vegetable colours.

[§ It sublimes without leaving any residue, and the portion that first comes over does not include any slender colourless prisms emitting a pungent odour.] By these tests non-volatile impurities, such as oxide of manganese or of iron, metallic iodides, etc. are excluded; the pungent crystalline body mentioned is iodide of cyanogen, an impurity commonly met with, even to a considerable extent, in crude iodine. A test should be added for the detection of the small quantity of chlorine which commercial iodine almost always contains. The following would be delicate enough for practical purposes:—A small quantity mixed with a slight excess of sulphurous acid gives a colourless solution, which, with nitrate of silver, strongly acidified by nitric acid, gives a yellowish-white precipitate of iodide of silver. This precipitate, after removal of the supernatant fluid, is insoluble in ammonia, and the ammoniacal liquid decanted gives no appreciable precipitate upon acidification by nitric acid.

[§ 1·27 gram dissolved in an ounce of water containing 20 grains of iodide of potassium requires for complete discoloration 100 cub. centims. of the volumetric solution of hyposulphite of soda.] The reaction between hyposulphite of soda and iodine results in a colourless solution, containing iodide and tetrathionate of sodium.

$$\underset{248\times 2}{2\,Na_2S_2O_3.\ 5\,H_2O} + \underset{127\times 2}{I_2}$$
$$= Na_2S_4O_6 + 10\,H_2O + 2\,NaI.$$

The volumetric solution is prepared so as to contain $\frac{1}{10}$th of half this quantity in a thousand parts of the solution, and therefore

1000 cub. centims. contain 24·8 of hyposulphite and will decolorize 12·7 of iodine.

Consequently

100 cub. centims. will decolorize 1·27 of iodine.

Strictly speaking, this mode of analysis is applicable only when chlorine and bromine are absent, for if present these bodies would, according to this method, be reckoned as iodine.

Liquor Ammoniæ Fortior.—Sal-ammoniac in coarse powder is mixed with lime, and the ammonia which is evolved on heating the mixture is conducted first through two empty bottles, in which the tarry impurities of the sal-ammoniac chiefly collect, then into a proper quantity of water, which absorbs the ammonia.

$$2\,NH_3HCl + CaO\,.\,H_2O$$
$$= 2\,NH_3 + CaCl_2 + 2\,H_2O.$$

Ammoniacal gas is excessively soluble in water and also in alcohol. The B.P. solution has a specific gravity = ·891, and a fluid drachm of it contains 15·83 grains of ammonia, or upwards of 380 times its volume of the gas. [§ When diluted with four times its volume of distilled water, it does not give precipitates with solution of lime, oxalate of ammonia, sulphide of ammonium or ammonio-sulphate of copper.] These tests indicate the absence respectively of carbonate of ammonia, of chloride of calcium, of metals such as copper or zinc, and of sulphide of ammonium. [§ And when treated with an excess of nitric acid is not rendered turbid by nitrate of silver nor by chloride of barium.] The solution is thus shown to be free from chlorides and sulphates.

The liq. ammoniæ of commerce almost invariably contains small quantities of tarry matters, including various organic bases; when nearly neutralized by an acid, their odour becomes distinctly perceptible.

Liquor Antimonii Chloridi.—Black sulphide of antimony, which should be finely powdered, is boiled with strong hydrochloric acid till dissolved; the solution is then strained, and duly concentrated by evaporation.

This solution cannot be diluted with water to any great extent, as it gives a white precipitate of oxychloride.

[See Antim. Oxidum.]

The commercial article is generally coloured with pernitrate of iron. [§ One fluid drachm of it, mixed with a solution of a quarter of an ounce of tartaric acid in four fluid ounces of water, forms a clear solution, which, if treated with sulphuretted hydrogen, gives an orange precipitate, weighing, when washed and dried at 212° F., at least 22 grains.] The best mode of performing this operation consists in keeping the liquid heated to near the boiling-point in a flask whilst the gas passes through it in a rapid stream. In this way, in about a quarter of an hour, a heavy sandy precipitate forms, which can be very rapidly filtered off and washed. Conducted in this way, the process is fairly accurate.

LIQUOR ARSENICALIS et LIQUOR ARSENICI HYDROCHLORICUS.—The former is a solution of white arsenic in carbonate of potash, the latter in hydrochloric acid, both containing 4 grains to the fluid ounce. The volumetric test has been explained under ACIDUM ARSENIOSUM.

LIQUOR BISMUTHI et AMMONIÆ CITRATIS.—A solution containing citrate of bismuth and ammonia and nitrate of ammonia. Three fluid drachms, precipitated by an excess of sulphuretted hydrogen, give 9·92 grains of sulphide of bismuth, corresponding to 8·99, or practically 9 grains of oxide of bismuth. A fluid drachm therefore contains 3 grains of oxide.

THE SEEDS OF TWO SPECIES OF STRYCHNOS.

BY J. M. MAISCH.*

Last fall, I was informed that a vessel, which had arrived at the port of New York from the East Indies, had brought, as ballast, a quantity of seeds of a species of strychnos. To the kindness of Dr. Fr. Hoffmann I owe some small sample of the same, and subsequently Messrs. M'Kesson and Robbins very kindly went to the trouble of hunting up for me a few pounds of the same seeds, which, under the name of Indian gum-nuts, were offered for sale in New York, without finding a purchaser. I felt interested to ascertain whether, like the seeds of some other strychneæ, they contain strychnia. I exhibited the seeds at the Pharmaceutical Meeting in February, and showed, at the same time, from my cabinet, some seeds of *Strychnos Tieuté*, Leschenault. This plant grows in the mountainous districts of Java, and its juice is used by the Malays to prepare the poison called upas radja, or upas tieuté tjettek. The tieuté seeds are orbicular or somewhat oblong, disk-like, resembling in shape nux vomica, five-eighths to three-quarters of an inch in diameter, yellowish-grey in colour, and covered with soft, appressed hairs, having a silky lustre; the disk is rather sharp-edged, with a slightly-projecting point, indicating the hilum, and covering the somewhat club-shaped radicle of the embryo. As in nux vomica, the white horny albumen has the shape of the seed, and is composed of two disks united near the circumference, thus enclosing a hollow space, into which the cotyledons project, occupying one-quarter to one-third the diameter of the cavity. The cotyledons are broadly oval, scarcely cordate, rather acute, three- to five-nerved.

Spach † describes the tieuté seeds as follows:—Elliptic, oval or sub-orbicular, velvety, brownish (*brunâtre*), lenticular, or plano-convex; embryo projecting from the hilum, marginal, about one-third shorter than the perisperm; cotyledons heart-shaped, acuminate, nerved, foliaceous; radicle club-shaped, as long as the cotyledons. The description corresponds closely with the tieuté seeds in my possession, the colour excepted.

The so-called Indian gum-nuts are subglobose, of an appearance as if composed of two unequally-convex halves, with an elevated line surrounding the largest circumference; they are of a dirty, somewhat brownish-grey colour, with very short, closely appressed hairs; the largest diameter is three-eighths to one-half inch. A rather thin, but hard integument covers a horny albumen, which encloses, as in nux vomica, an orbicular cavity, into which the embryo reaches to about one-third the diameter. The radicle is marginal, short, cylindrical; the cotyledons are broadly oval, somewhat acuminate, and about three-nerved. Notwithstanding the horny texture of the albûmen, the seeds are readily broken in an iron mortar, but are difficult to powder; their taste is insipid, not bitter.

When the seeds are boiled with dilute muriatic acid, they become very soft, so that they are readily mashed between the fingers; the acid decoction, which is not precipitated by iodohydrargyrate of potassium, was treated with an excess of lime, the precipitate washed with cold water, dried, exhausted with boiling alcohol, and the clear filtrate evaporated; a yellowish mass was left without the slightest tendency to crystallize. It had an insipid taste, and did not show the colour reactions of either brucia or strychnia; concentrated sulphuric acid decomposed it rapidly. The seeds, therefore, contain no alkaloid.

In the East Indies, the seeds of *Strychnos potatorum*, Linn. fil. are used for clearing muddy water, under the name of tettan-kotta, or clearing-nut. Spach* describes them as greyish, suborbicular, about five lines in size. Dr. Waring † says that they are of a flattened, spherical form and yellowish-grey colour, having the testa covered with short, close hairs; albumen horny and tasteless. As far as they go, these descriptions agree with the Indian gum-nuts, which I believe to be derived from *Strychnos potatorum*, Linn. fil.

According to the Pharmacopœia of India, these seeds are also used in native practice as an emetic (Ainslie), as a remedy in diabetes (Kirkpatrick), gonorrhœa (Taleef Shereef), etc. On what principle the clearing action depends is a matter of speculation. Dr. O'Shaughnessy, at one time, thought it was due to an astringent principle, while Pereira‡ supposed it to depend on the presence of albumen and casein, and Guibourt attributes it to mucilage or pectin. The seeds are free from tannin, contain but little albumen, while, in the few experiments instituted by me, I could not ascertain the presence of casein or pectin. A considerable proportion of a peculiar mucilage is present, which does not yield a very ropy solution, and is not precipitated by alcohol, acetate of lead or sesquichloride of iron. If vegetable matter is suspended in water, the turbid liquid put into two glass vessels, and solution of this mucilage added to one, the latter liquid will settle the suspended matter in a short time, while the other remains turbid much longer.

The testa appears to offer obstructions to the absorption of water by the albumen; for, if the testa be unbroken, the seeds may be immersed in cold water for twenty-four hours, and still retain their hardness; but, if the testa is partly removed, or the seeds are broken, the albumen, after twelve hours' immersion in cold water, becomes soft enough to be readily split by the finger-nail.—*American Journal of Pharmacy.*

THE MEDICINAL PROPERTIES OF THE COCOA-NUT.

BY JOHN R. JACKSON, A.L.S.,

Curator of the Museums, Royal Gardens, Kew.

The cocoa-nut (*Cocos nucifera*, L.) is a well-known economic plant, and is extensively cultivated in tropical countries. It is estimated that in Travancore alone there are ten million of these trees growing. The fruits are a most important article of food in the countries where they grow, while the oil and the fibre of the husk—known as coir—are valuable articles in British commerce.

The cocoa-nut is not a recognized medicinal plant in European practice, though the oleine obtained by pressure from the crude oil and refined, has been used as a substitute for cod-liver oil, experiments having shown that its effect in increasing the weight of the body is almost equal to that of the latter, but that its continued use is apt to disturb the digestive organs and produce diarrhœa. The crude oil, as brought into England, is obtained by boiling and pressing the white kernel or albumen. While in a fresh state, and in a liquid form, this oil is of a pale yellow colour, and almost without smell; it is much used in cookery by the natives, but becomes partially solid and turns rancid before it arrives in this country, where, for the purposes of the candle-maker, the stearine or solid fat is separated from the fluid. Cocoa-nut oil is said to be useful in strengthening the growth of the hair.

The milk of the cocoa-nut is more important to the natives in a medicinal point of view than the oil; in India they use it as a purifier of the blood, and we have heard from many an English resident in our eastern possessions, that it is not only an excellent medicine for the purpose, but that nothing can possibly be more refreshing to a thirsty traveller under a tropical sun than a good draught of fresh cocoa-nut milk. As we obtain it in this country, it has not only lost its freshness and fine flavour, but has also lost its medicinal properties. When quite fresh it has been employed successfully by English doctors in India in cases of debility and incipient phthisis, and it also forms an excellent substitute for, if indeed it is not preferable to, cow's milk for tea and coffee. In large doses, however, it is said to act as a purgative, and on this account has been recommended in lieu of castor oil for those who cannot overcome the nausea arising from the latter. In the Fiji islands the milk is very extensively used, but it has been supposed, with how much truth we are not able to say, that the continued use of it predisposes to the dropsical complaints which are said to prevail in those islands.

The toddy or wine which is obtained from the flower-spikes is described as being very refreshing and delicious, taken before sunrise; it is given by the native doctors in cases of consumption, and if taken regularly is said to be an excellent medicine for delicate persons suffering from habitual constipation.

FLUID EXTRACTS AND THEIR MENSTRUA.

BY EDWARD R. SQUIBB, M.D.

(*Continued from page* 6.)

The following table, embracing the substances of nine officinal fluid extracts, and one other, is limited in extent by the size of the page, but is large enough to illustrate these points. These percolations, excepting ergot and lupulin, were all made with fine powders, moistened with more menstruum than is directed by the Pharmacopœia,

and the moistened powder put through a sieve of about twelve meshes to the inch before the packing. The packing and percolating was then done with all the care and skill which the writer's experience could suggest, so that the results are considered to be much better than an average practice would give. Each pint of percolate was weighed in a flask marked in the narrow part of the neck, and the menstruum at the same temperature was weighed in the same flask, and the difference in weight set down in the column under that heading. The same powder, managed in the same way, was percolated at once; and another portion, after macerating four days, with no practical difference in result; whilst a maceration of twenty-four hours after the third or fourth pint of percolate had passed, would always increase the difference somewhat, and would often increase them much. Changes of temperature, also, by changing the solvent power of the menstruum, caused the differences to rise and fall somewhat, coincident with changes of weather. A simple inspection of the proportion of the extract contained in the first pint of each percolate will probably expose the fallacy that any amount of expert skill and management could ever make that pint represent the whole efficacy of the drug. In percolating the powder of good aconite root by a very slow and careful percolation, the characteristic numbing impression upon the tongue was distinctly though faintly perceptible by the application of a few drops from the thirteenth pint. The bitterness of cinchona was perceptible in the seventeenth pint; but neither the taste nor odour of wild cherry bark were perceptible in the sixteenth pint, though the amount of extract contained was large. Ergot was necessarily percolated in coarse powder (No. 60), and was easily and rapidly exhausted; but the dried residue powdered finer gave a notable proportion of extract, which, for want of time, was not determined. Not so with lupulin, however, which, percolated in its natural condition of coarse powder, left a light residue, from which no ordinary management could extract anything more. The percolation of lupulin was very regular and uniform, and maceration at any stage of the process had no perceptible effect. Effective percolations of dandelion-root are very slow, and therefore very perfect; and like those of sarsaparilla, often become slower as they approach completion.

The great difference in the rate of exhaustion in the examples given in the table indicates that no general rule of limit can be adopted, but that each substance must be studied by itself. From results given in a previous paper, the solid extract obtained by percolation from some drugs, and probably from all, is not of uniform medicinal value as found in different parts of the percolate, but becomes weaker towards the end. When this ceases to be of practical value, or, in other words, where the percolation should terminate, was not determined. Among the examples given it will be seen that if the Pharmacopœia used fine powder and slow percolation, it would, in the case of dandelion, obtain 86 per cent. of the total extract; and it is probable that this is somewhere near or beyond the limit of practical utility. If so, it might be directed that fluid extracts as a class of preparations should not contain less than 80 per cent. of the total solid extract which the drugs were capable of yielding to the given menstruum; and the limit of percolation necessary to obtain this is shown by one of the lines of the table. But where this 80 per cent. of the solid extract has been obtained, it is not within the compass of a pint, but is contained in a number of pints, never less than 2½ nor more than 11.

To get these various large quantities within the measure of a pint each without the use of heat, and with the least loss of menstruum, is the next and great requisite, without which they are not fluid extracts.

To accomplish this, there appears to be no choice of means. There is one way, and only one way, known to the writer by which it may be done, and that is by repercolation, or percolating fresh portions of the drug with percolate from previous portions, until the normal difference in weight between equal volumes of the menstruum and percolate is attained.

This process is somewhat complex and troublesome, and requires knowledge and skill; and, worse than all, requires that a stock of weak percolate of different densities be carried from one making to the next for each fluid extract. But, as it appears to be absolutely the only means of accomplishing the end well and properly, there is no choice between it and those means which give results too imperfect for the present state of pharmacy.

(*To be continued.*)

GLYCERINE; ITS QUALITY AS IT EXISTS IN COMMERCE.

BY JOSEPH P. REMINGTON, PHILADELPHIA.

This powerful solvent and useful medicine, though but lately called from its seclusion in the cabinet in answer to the demands of this progressive age, has rapidly ingratiated itself into the esteem of the chemist, pharmacist, and the public at large.

It continues to widen its sphere of usefulness; we hear of new applications constantly; and its *bland manners* and *insinuating disposition* have won for it a host of friends, and an ever-increasing popularity.

It serves its mission as faithfully on the dressing-table of a lady as it does in our gas meters; as well as an excipient for pill-masses as it does as a substitute for molasses in printers' rollers, and its range of applications between these extremes is varied and extensive.

Its production, with a view to improve the quality and lower the price, has been attended with success, as we all know. A glycerine which will answer almost every purpose (except for internal administration), can be procured for twenty-five cents per pound; and one fit for any purpose for sixty cents per pound.

One of the principal reasons for bringing this matter forward, is to detail a comparative examination of the different brands in the market, which examination was at first undertaken for the writer's own satisfaction, but which may prove not uninteresting to the Association.

Brands.	For Strength. Sp. Gr.	Colour.	Odour when warm.	Nitrate of Silver.
1	1·253	None.	None.	No precip.
2	1·240	Yellowish.	Fatty.	Heavy wh. prc.
3	1·250	Yellowish.	Slight.	Rose colour.
4	1·254	None.	Empyreumatic.	No precip.
5	1·250	Quite dark.	Like glue.	White precip.
6	1·245	None.	Slight.	Rose colour.

Brands.	Sulphuric Acid.	For Sulphate of Lime.	For Lime Salts Ox. Ammon.	Ferrocyanide of Iron.
1	Slightly discol.	No precip.	No precipitate.	Opalescence.
2	Discoloured.	No precip.	Slight precip.	Clear.
3	Discoloured.	No precip.	No precipitate.	Opalescence.
4	Discoloured.	No precip.	No precipitate.	Precipitate.
5	Slightly discol.	No precip.	White precip.	Slight precip.
6	Discoloured.	No precip.	No precipitate.	No precip.

Brands.	Hydro-sulph. of Ammon.	Chloride of Barium.	For Ethyl-Butyrate.	For Sugar.
1	No precip.	No precip.	Slight odour.	Free fr. sugar.
2	No precip.	Slight precip.	Strong odour.	Free fr. sugar.
3	No precip.	Precipitate.	Slight odour.	Free fr. sugar.
4	No precip.	No precip.	Veryslight odour	Free fr. sugar.
5	No precip.	Opalescent.	Slight odour.	Free fr. sugar.
6	Slight precip.	No precip.	Slight odour.	Free fr. sugar.

Each glycerine was tested by the same reagent, in the same relative quantity, at the same time; and the effect carefully noted.

The glycerines, as they stood in their commercial attire before the examination, presented quite a contrast; the most pretentious was one of the latest comers into the market, No. 6; which, from the size of the bottle, would lead to the supposition that it contained more than a pound. This glycerine has attracted attention by reason of the free use of adjectives on the label, and on account of a vigorous attack on the propriety of using adjectives by the editor of a trade journal.

No. 5 is put up in a very attractive style, the blue stencilled label and the refractive property of the glycerine contrast to very good advantage.

The American glycerines were in a plainer and neater dress, Nos. 1, 2 and 3 being put up in the usual glycerine bottle with a plain label.

The result will be found in the foregoing table.—*Proceed. of American Pharm. Assoc.*, 1870.

SUPPOSITORIES.

AN INAUGURAL ESSAY, BY F. M. GOODMAN.

The etymology of the word suppository conveys at once an idea of the use of the class of pharmacal preparations to which it is applied. It is derived from suppositorius —"underneath"; called also hypotheton, from *hypo* "under," and *tithemi*, "to place;" and sometimes balanus (*balanos*), an "acorn," in reference to the shape, that of a sphere or an oblong body; these were intended for rectal use only.

As it became evident that medicines applied to the mucous membranes of the vagina or rectum had the same systemic effect as when taken into the stomach, and that, being so applied, they were less repulsive to the patient, advantage was soon taken of this form of administration. It then became necessary to distinguish between rectal and vaginal suppositories, consequently the former were called *suppositorium*, and the latter *suppositorium uterinum*, which were the medicated pessaries of the ancients, and are still frequently prescribed as pessaries; in fact, medicines applied to *any* of the mucous membranes were called suppositories—what is now termed a lozenge or troche, was formerly known as a suppository, or bacilla, the latter signifying "a stick."

From this method of treatment arose the custom, though not as yet very prevalent, of applying medicines in the solid form to the urethra, in the treatment of urethritis, etc.

It is only within the last decade that this method of medication has reached a state approaching to perfection, but it is now such an important feature that it is almost of daily occurrence to dispense suppositories, though we have no officinal directions for their preparation. To those unaccustomed to dispensing suppositories, their preparation often proves a difficult task, but by experience one may become so expert as to make a dozen within fifteen or twenty minutes, so that a patient is not called upon to wait longer for suppositories than for a dozen pills or powders.

MOULDS.—These are in great variety, but the most common are conical-shaped, and made of block tin; they are of two sizes, the vaginal and rectal; the former making a suppository weighing 2 drachms, and the latter one of 35 grains. It is customary for pharmacists to have these two sizes, but if an intermediate size were furnished, such as would mould suppositories weighing 1 drachm each, the latter size would satisfy the majority of physicians better than those now dispensed. It is complained that the large are *too* large, and the small are *too small*, but if of the size above indicated, they could be used as vaginal or rectal, in most cases.

In using these moulds a tray is necessary, which may be constructed in the following simple manner: For one dozen vaginal moulds, purchase a tin pan about 7 or 8 inches in diameter and 4 inches in depth; have a sheet of tin cut to fit the pan about half an inch from the top, perforate the tin with holes sufficiently large to allow of the ready admission and removal of the moulds; of course, the rectal moulds will require a smaller pan, or the same pan and a sheet of tin with smaller holes.

If the inside of these moulds be examined, there will be observed a great number of annulations made by the instrument used in turning the model from which they were cast, but by polishing, these rings may be worn off, when the inside becomes very smooth. It is on this account that suppositories are best made in old moulds.

A very nice mould, called Weigand's, invented by Mr. T. S. Weigand, of Philadelphia, is made on the principle of the ordinary bullet mould: two parallel bars of brass, with the proper cavities in each, are hinged at one extremity, and have handles at the other; these moulds, when in use, are kept closed by slipping a ring, made for the purpose, over the handles.

They are made for six, nine, or twelve suppositories, which weigh about 40 grains each.

It has been asserted that these moulds are worthless, cracking the suppository in two, when opened, even when lycopodium, arrowroot, or other substance has been used to prevent adhesion. The writer has used these moulds a great deal, and has found the only and a *sure* way of making a perfect suppository is to have the moulds *thoroughly refrigerated, and their surfaces well polished;* when the latter requisite is once attained, it can be easily preserved by rubbing whiting with a piece of chamois skin into the moulds each time, before putting them away, and wiping with the chamois before using. Wiegand's moulds may be refrigerated very perfectly without the use of ice, in the following manner:—Close them, and place the handles in the spout of a hydrant, allowing the orifices of the moulds to be downward; place a box in the sink on which to rest the lower end, and set the water running gently over the moulds, before beginning to melt the ingredients; when wanted, wipe them quickly and fill; then set them into a shallow vessel containing water, and when a pellicle has formed on the surface of each suppository, replace the moulds under the hydrant. Some object to this method, saying that the water in passing over the suppositories dissolves out some of their soluble ingredients; but this cannot be considered an objection, for the moulds are very seldom or *never* filled exactly full, but a little too much is poured into each; and when they are cold enough to be removed, the superfluous material is scraped or trimmed off with a spatula, before the opening of the moulds. In doing this, the portion that has been exposed to the influence of the water is removed.

Moulds are also made of paper, by having a piece of wood about six inches long, one end of which is formed into the shape of a suppository, which must be perfectly conical, and *not* like the ordinary suppository, which is more or less *rounded* at the apex; for if it be rounded in the least, it is impossible to wrap the stiff paper around it so as to make a neat-looking mould.

The paper for this purpose may be thick writing-paper; tinfoil is also sometimes used, and answers the purpose very well. When in use, these moulds are held in an upright position by placing them in round holes bored through a thin board, or by standing in a vessel filled with flax-seed, or other suitable substance.

The urethral mould, or syringe, as it is commonly called, is simply a glass or hard rubber tube, three or four inches in length, having a piston fitted to it. The calibre of these moulds is sufficiently large to make a suppository about an eighth or three-sixteenths of an inch in diameter, which is to be an inch and a half or two inches long, and to weigh from 7 to 14 grains. In using these moulds, two lengths are moulded at once, and the piece in then cut in the centre. An ordinary funnel-tube answers the purpose of a mould admirably, for if such a tube be used, say twelve inches long, it can be graduated by scratching with a file, into two-inch spaces.

In the suppository syringe the piston is a rod of glass, with cotton wrapped around it at about *half an inch from the end*, and this uncovered portion of the rod disfigures the end of the suppository when any pressure is used in expelling it. For this reason the funnel-tube is preferable, for the piston being of wood can be cut, and wrapped close to the end, which may be made of the same diameter as the suppository, so as not to mar it.

VEHICLE.—That recommended by the British Pharmacopœia is composed of equal parts of prepared lard and white wax, but this is a very poor vehicle; among the objections to it is, that pharmacists *very seldom or never* render or prepare lard for their own use, and consequently rely upon the integrity of the packers, or butchers; now it is well known that commercial lard is impure—that the renderers frequently stir in water, and occasionally a solution of sulphate of copper or of alum, salt, etc., to whiten it; of course the lard is thereby rendered unfit for pharmacal uses.

The vehicle of the B.P. is objectionable also as regards its melting-point, which is 104° F. (40° C.), or much above the temperature of the human body.

The substance most usually employed for the purpose in the United States, is a mixture of cocoa butter and spermaceti, in the proportion of four-fifths of the former to one-fifth of the latter, in summer, and five-sixths to one-sixth in winter; the above proportions will answer also for cocoa butter and white wax. These mixtures become soft at 79° F. (26·1° C.), and 82° F. (27·7° C.), respectively, and consequently readily melt at the temperature of the body, in this respect answering an essential requirement of suitable vehicles, and as such they are generally employed.

But why should these substances be used when in sevum or suet we have a material that answers all the requirements of a good vehicle? Suet has about the same *softening*-point, 80° F. (27·6° C.), and is doubtless superior to the above mixtures in this: that it sets or cools much more readily. This constitutes quite an advantage, while the expense of the material is only about *one-sixth* that of the former. To prepare it, take the kidney suet of *Ovis Aries*, and purify as directed in the Dispensatory, by cutting into small pieces and melting over a moderate heat, and straining through linen. According to the Dispensatory, suet is inodorous, but practically it is never free from an odour, which is rather disagreeable, but which may be overcome by the addition of a small quantity of an essential oil to the cooling mass. For this purpose I use a mixture of the oils of lavender and sassafras in equal parts; about two or four minims to the troy ounce is sufficient. This addition not only destroys the odour, but acts as a preservative, and prevents the suet from becoming rancid as soon as it otherwise would; a solution of benzoin is also very good for this purpose. After the oils or benzoin have been added, the melted fat should be poured into cold, shallow vessels, such as the covers of earthenware jars, in order to get it in sheets resembling white wax. Prepared in this manner it will keep a considerable length of time—usually as long as is required,—and the stock can at any time be renewed.

Suet is capable of absorbing about 1 fluid drachm of water to the troy ounce, so that it is easy to combine with it a concentrated mucilage of elm (which also acts as a preservative), or an aqueous solution of an extract, or of salts of various kinds. Some object to adding water to suppositories, as it promotes rancidity, but this is not a very serious objection, for finished suppositories are not required to be long kept. Water has the same effect upon cocoa butter as upon suet or lard. These bodies if exposed to the air absorb oxygen, and become quite acid; the fatty acids are naturally in combination with glyceryle, but they will not combine with the hydrate of that base, and the presence of water accelerates the decomposition of fats, inasmuch as it supplies all that is necessary—in connection with the absorption of oxygen—to form a hydrate of the oxide of the radical glyceryle, $C_6H_5O_3 + 3HO$, or glycerine, with the elimination of fatty acids. The fluids thus set free, separate from the concrete matter, and as a consequence rancid fats have the appearance of a mixture of a solid granular substance and a fluid. These fatty acids produce the irritating properties possessed by rancid fats.

In former times soap was frequently employed for suppositories, but is seldom used at present.

DUST AND SMOKE.

(*Continued from page* 5.)

Let me now state in two sentences the grounds relied upon by the supporters of the germ-theory of contagion. From their respective viruses you may plant typhoid fever, scarlatina, or smallpox. What is the crop that arises from this husbandry? As surely as a thistle rises from a thistle seed, as surely as the fig comes from the fig, the grape from the grape, the thorn from the thorn, so surely does the typhoid virus increase and multiply into typhoid fever, the scarlatina virus into scarlatina, the small-pox virus into small-pox. What is the conclusion that suggests itself here? It is this:—That the thing which we vaguely call a virus is to all intents and purposes a *seed;* that in the whole range of chemical science you cannot point to an action which illustrates this perfect parallelism with the phenomena of life—this demonstrated power of self-multiplication and reproduction. There is, therefore, no hypothesis to account for the phenomena but that which refers them to parasitic life.

And here you see the bearing of the doctrine of Spontaneous Generation upon the question. For if the doctrine continues to be discredited as it has hitherto been, it will follow that the epidemics which spread havoc amongst us from time to time are not spontaneously generated, but that they arise from an ancestral stock whose habitat is the human body itself. It is not on bad air or foul drains that the attention of the physician will primarily be fixed, but upon diseased germs which no bad air or foul drains can create, but which may be pushed by foul air into virulent energy of reproduction. You may think I am treading on dangerous ground, that I am putting forth views that may interfere with salutary practice. No such thing. If you wish to learn the impotence of medical science and practice in dealing with contagious diseases, you have only to refer to a recent Harveian oration by Dr. Gull. Such diseases defy the physician. They must burn themselves out. And, indeed, this, though I do not specially insist upon it, would favour the idea of their vital origin. For if the seeds of contagious disease be themselves living things, it will be difficult to destroy either them or their progeny without involving their living habitat in the same destruction.

And I would also ask you to be cautious in accepting the statement which has been so often made, and which is sure to be repeated, that I am quitting my own *métier* when I speak of these things. I am not dealing with professional questions. I am writing no prescription, nor should I venture to draw any conclusion from the condition of your pulse and tongue. I am dealing with a question on which minds accustomed to weigh the value of experimental evidence are alone competent to decide, and regarding which, in its present condition, minds so trained are as capable of forming an opinion as on the phenomena of magnetism and radiant heat. I cannot better conclude this portion of my story than by reading to you an extract from a letter addressed to me some time ago by Dr. William Budd, of Clifton, to whose insight and energy the town of Bristol owes so much in the way of sanitary improvement.

"As to the germ theory itself," writes Dr. Budd, "that is a matter on which I have long since made up my mind. From the day when I first began to think of these subjects, I have never had a doubt that the specific cause of contagious fevers must be living organisms.

"It is impossible, in fact, to make any statement bearing upon the essence or distinctive characters of these fevers, without using terms which are of all others *the most distinctive of life*. Take up the writings of the most violent opponent of the germ theory, and, ten to one, you will find them full of such terms as 'propagation,' 'self-propagation,' 'reproduction,' 'self-multiplication,' and so on. Try as he may—if he has anything to say of those diseases which is characteristic of them—he cannot evade the use of these terms, or the exact equivalents to them. While perfectly applicable to living things, these terms express qualities which are not only inapplicable to common chemical agents, but as far as I can see actually inconceivable of them."

Once then, established within the body, this evil form of life, if you will allow me to call it so, must run its course. Medicine as yet is powerless to arrest its progress, and the great point to be aimed at is to prevent its access to the body. It was with this thought in my mind that I ventured to recommend, more than a year ago, the use of cotton-wool respirators in infectious places. I would here repeat my belief in their efficacy if properly constructed. But I do not wish to prejudice the use of these respirators in the minds of its opponents by connecting them indissolubly with the germ theory. There are too many trades in England where life is shortened and rendered miserable by the introduction of matters into the lungs which might be kept out of them. Dr. Greenhow has shown the stony grit deposited in the lungs of stonecutters. The black lung of colliers is another case in point. In fact, a hundred obvious cases might be cited, and others that are not obvious might be added to them. We should not, for example, think that printing implied labours where the use of cotton-wool respirators might come into play; but I am told that the dust arising from the sorting of the type is very destructive of health. I went some time ago into a manufactory in one of our large towns, where iron vessels are enamelled by coating them with a mineral powder, and subjecting them to a heat sufficient to fuse the powder. The organization of the establishment was excellent, and one thing only was needed to make it faultless. In a large room a number of women were engaged covering the vessels. The air was laden with the fine dust, and their faces appeared as white and bloodless as the powder with which they worked. By the use of cotton-wool respirators these women might be caused to breathe air more free from suspended matters than that of the open street. Over a year ago I was written to by a Lancashire seedsman, who stated that during the seed season of each year his men suffered horribly from irritation and fever, so that many of them left his service. He asked me could I help him, and I gave him my advice. At the conclusion of the season this year he wrote to me that he had simply folded a little cotton-wool in muslin, and tied it in front of the mouth; that he had passed through the season in comfort and without a single complaint from one of his men.

The substance has also been turned to other uses. An invalid tells me that at night he places a little of the wool before his mouth, slightly moistening it to make it adhere; that he has thereby prolonged his sleep, abated the irritation of his throat, and greatly mitigated a hacking cough from which he had long suffered. In fact, there is no doubt that this substance is capable of manifold useful applications. An objection was urged against the use of it: that it became wet and heated by the breath. While I was casting about for a remedy for this, a friend forwarded to me from Newcastle a form of respirator invented by Mr. Carrick, an hotel-keeper at Glasgow, which meets the case effectually, and, by a slight modification, may be caused to meet it perfectly. The respirator consists of a space under a partition of wire-gauze, intended by Mr. Garrick for "medicated substances," and which may be filled with cotton-wool. The mouth is placed against the aperture, which fits closely round the lips, and the air enters the mouth through the cotton-wool, by a light valve, which is lifted by the act of inhalation. During exhalation this valve closes; another breath escapes by a second valve, into the open air. The wool is thus kept dry and cool; the air in passing through it being filtered of everything it holds in suspension.*

IMPROVED DOVER'S POWDER.

BY B. D. KEATOR, M.D.

A very convenient and useful compound is Dover's Powder; but, unfortunately, a very *nauseous* one. I have for several years past had it under consideration, making various changes in its composition; but until recently with poor success. The diaphoretic powder of Dr. Tully, and also that lately recommended by Dr. Brinsmade, I have found on trial to be good *anodynes*, but far inferior in *diaphoretic* effect to the old Dover. The ipecacuanha cannot be dispensed with, but I think the opium and sulphate of potash (the main nauseants) *can* be replaced with better ingredients. Ipecacuanha, in doses under half a grain is anti-emetic, and "not guilty" in the nauseous taste of Dover.

Out of Dover's, Tully's and Brinsmade's powders I have compounded a *fourth*, which I believe contains the excellences of *all*. There is 1 gr. of ipecacuanha, and one-sixth gr. sulph. morphia (equal to 1 gr. opium) to every 10 grs. of the mixture. The camphor adds much to it as an anodyne; the chalk is anti-acid, and necessary to hold the camphor in pulverized form; and the liquorice, besides disguising the taste of the rest, is of itself useful as a demulcent, expectorant, etc. I can confidently recommend this to my brethren of the profession who choose to give it a trial, as *superior to the old Dover's powder in every respect*.

℞ Sulph. Morphiæ gr. x
Pulv. Camph. ʒiij
,, Ipecacuan. ʒj
Cretæ Præparat. ʒiij
Pulv. Glycyrrh. ʒiij.

Thoroughly mix. Dose same as Dover (in water).

Milk an Antidote to Poisoning by Nitrate of Silver.—Mr. Ernest Hart, in a recent number of the *British Medical Journal*, relates that while house-surgeon at St. Mark's Hospital, a piece of nitrate of silver, with which he was painting the fauces of a child, broke, and the larger part of the caustic stick was swallowed. He produced immediate vomiting by forcing his fingers on to the gullet, and having obtained a large supply of milk, pumped several pints into the child's stomach and out again. The child had dysenteric symptoms during the next three days and occasional vomiting, but was kept on milk diet and recovered. Milk acts as an antidote to nitrate of silver in virtue of its large proportion of suspended albumen. Mr. Hart uses it in lieu of salt and water for neutralizing the excessive effects of even the mitigated caustic, when employing it locally on the mucous membrane of the eyelids.

---

* Mr. Ladd, of Beak Street, sells these respirators.

The Pharmaceutical Journal.

SATURDAY, JULY 8, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

ACCIDENTAL POISONING.

THE cases reported in the present and preceding numbers of this Journal opportunely illustrate some of the sources of danger attending the keeping and dispensing of poisons. These cases are also of special interest while this Society is engaged in opposing "the regulation of pharmacy" which is proposed in shape of the Pharmacy Act Amendment Bill now before the House of Commons.

In the first place, the death of the two children from the effects of a poisonous dose of opium administered by mistake, affords striking support to the argument that regulations as to the keeping and dispensing of poisons—if they be imposed at all—ought to be imposed so as to affect all classes of persons who dispense medicine. We apprehend the force of that argument must be apparent to every one who considers the subject even cursorily. For what is the object to be gained by regulation? Protection from poisoning by the accidental substitution of one drug for another. It is as a measure for ensuring public safety that these regulations are proposed to be made compulsory; and, considering the matter from that point of view, it seems impossible to conceive why medical dispensers should be exempted from the obligation of conforming to any regulations prescribed as to the keeping and dispensing of poisons. We here purposely leave aside the purely pharmaceutical question, whether or not there be any need for pharmacists to be subjected to compulsory regulation, for that is a question of comparatively less importance than that affecting the whole community; and even admitting that there be, on the part of the public, a demand for protection against accidental poisoning, we cannot imagine any one being less unwilling to be poisoned by a medical man than by a pharmacist.

We are glad to see this view of the case fully adopted by at least one of the medical papers in the statement that—

> ". . . . no protection against poisoning can be complete or satisfactory, which does not include medical dispensers. The risk of accident would appear, *primâ facie*, to be even greater in their case than in that of pharmacists, inasmuch as their functions and attention are not solely given to the making up of medicines."

In a subsequent number, also, the same paper speaks of the above-mentioned fatal case of poisoning as being "but another instance of the abominable way poisons are stored in apothecaries' shops." Numerous correspondents in this Journal have pointed to the same fact; and certainly the evidence given by "Mr. JOHN LEVYGILL, the apothecary at the dispensary," seems to afford ample ground for the remark, and for the opinion that in medical Dispensaries the possible substitution of poison for physic is neither efficiently provided against nor regarded with sufficient seriousness.

It is probably from a sense of these deficiencies that the Parliamentary Committee of the British Medical Association in considering the Pharmacy Act Amendment Bill, resolved—

> "That it is desirable that provision should be made for the carrying out the regulation for keeping, dispensing and selling poisons, and that for this purpose a clause should be introduced providing inspectors to ascertain that they are carried out."

We understand that the view we have here put forward is favourably entertained by the Privy Council, and that Mr. FORSTER is now disposed to introduce into the Bill amendments that would give it the more extended application to all dispensers of medicine.

Contrasting strongly with the state of things illustrated by the case referred to is the caution evidenced, as regards the sale of a dangerous drug, by a pharmaceutical chemist in the other fatal case of poisoning reported this week. It would perhaps be difficult to have done anything more for "public safety" than was done in that case, for the too frequent practice of amateur doctoring is a source of danger that would override even the most stringent compulsory regulations.

Another point illustrated by the Dispensary case is the vagueness of the Poison Schedule of the Act of 1868, and the difference of opinion as to what is to be regarded a poison within the meaning of the Act. Kino powder is a preparation of opium, and, though it contains a larger amount of opium than paregoric does, there is still a possibility that either might poison. It seems, therefore, that the exercise of judgment and caution by the competent vendor or dispenser of drugs is, after all, the safest protection against accidental poisoning. The granting of a monopoly of the business of pharmacy to such competent men was indeed a measure mainly taken in the interests of the public; and, though it has, no doubt, been the means of improving that business for its followers, there is nothing to justify the taunting tone in which the "monopoly" enjoyed by the Pharmaceutical Society is often spoken of in some of the medical journals. Rescinding that monopoly is surely an inconsistent suggestion from those who study the protection of the public from accidental poisoning, and who maintain this to have been the "public advantage" for the sake of which the "monopoly" was granted.

In the foregoing remarks we have considered accidental poisoning more especially as a subject of general interest than as one specially affecting pharmacists, because "public safety" is the reason urged in favour of the proposed regulations.

The contention for regulations on that ground does away with the objection we once incidentally made to the argument, that the regulations should not be made compulsory, because medical men would be exempt from that compulsion. We believe that argument to be fallacious as regards the narrower question, whether regulations should be made compulsory for pharmacists, for if regulations are to be contended against from that point of view, we should prefer to see it done on the more rational ground that—as regards pharmacy—they are not necessary. But whenever the imposition of poison regulations comes to be treated as a measure of public safety, it is no longer a mere question concerning pharmacy, and regard must be had to all sources of danger—medical as well as pharmaceutical.

It might have been supposed that, after all the discussion on poison regulations, the real points at issue would be understood; but that is not the case, and it was with no small surprise we recently read the statement that one of the two things evident from the interview with the Vice-President of the Privy Council was, that that body conceived it "to be a duty devolving on them to insist on the necessity of poisons being *sold under certain well-defined regulations*." The italics are ours, and they serve to show what strange misconceptions are possible. Surely it is not now necessary for the Privy Council or the trade, or even the public, to be told either that poisons are legally sold under certain well-defined regulations, or that there is no question at issue respecting the sale of poisons under the Pharmacy Act of 1868.

There are no doubt several questions still to be be considered as to the illegal sale of poisons, interesting and important to both the public and pharmacists, and to these we hope soon to have an opportunity of referring. At present, however, there is no moot point concerning the sale of poison, and since it is always desirable during a period of conflict to have the points at issue clearly defined, it may not be superfluous to say that the disputed question is one solely as to the *keeping and dispensing of poisons*,—in other words, whether regulations require to be made compulsory on pharmacists, and whether they are to be the only persons subjected to penal restrictions in this respect.

Postscript, *Friday Evening*.—In consideration of the interest that must be felt as to the proceedings in Parliament when the second reading of the Pharmacy Bill came on, it has been deemed proper to postpone the issue of the Journal sufficiently to admit of a report being published. This will be found at page 34.

We are also enabled by this delay to state that certain amendments which Mr. Forster expressed his willingness to introduce into the Bill, were submitted confidentially to the Council at its last meeting, and that after prolonged consideration the Council resolved, by a majority, that the suggested amendments did not permit the withdrawal of opposition to the Bill. This had been communicated to the Right Honourable Mr. Forster and to Mr. W. M. Torrens, M.P., who had given notice to move that the Bill be read a second time three months hence, and when the Bill came before the House at 1.15 this morning, Mr. Torrens proposed that for convenience, and in consideration of the altered views of the Government, the second reading of the amended Bill should be taken then on condition of Mr. Forster consenting that the discussion on the merits of the Bill should be deferred until it was in Committee. This course was objected to by the House on principle, and at the suggestion of Sir H. J. Selwin-Ibbetson, it was agreed that the amendments introduced by the Government should be placed on the paper so as to afford opportunity of their being circulated throughout the country and considered by those interested. We are consequently enabled to publish the Bill in its amended form. (See page 35.)

Referring to our previous remarks as to the object of the original Bill, it seems desirable to point out that the misconception on this head appears to be more general than we had supposed when those remarks were written; for Dr. Dalrymple, in expressing his regret at finding such a strong opposition to the Bill, singularly enough stated that the principle involved in the Bill being read a second time was that *a right existed to put certain restrictions on the sale of poisons*. In point of fact, however, restriction of the *sale* of poisons was not the main object of the original Bill. Neither would the amended Bill affect the sale of poisons otherwise than by extending the provisions of the Pharmacy Act of 1868 to surgeons keeping open shops for the sale of poisons, and thus placing them, in this respect, on the same footing as druggists, who have been for nearly three years subject to a law specifically regulating the sale of poisons.

The circumstance here referred to is alone sufficient to show the need of time for the due consideration of the proposed measure, and we venture to hope the attitude of Mr. Forster, who has charge of this measure, may be taken as an earnest that the ultimate result may be satisfactory to all parties.

In any case his introduction of amendments, with the object of meeting objections to the Bill by druggists, would seem to show there is little fear of a realization of the hope expressed by the *British Medical Journal*, and re-echoed by the *Lancet*, that a clause should be inserted to provide for the inspection of druggists' shops.

Certainly the general reception of the Bill in the House this morning did not appear to bear out the announcement in the *Lancet* last week, that the Government was prepared to carry it, without regard to the objections of those most interested; and the prediction ventured this week that a few hours would probably decide the fate of the Bill was strikingly negatived at the very moment when that prediction was passing through the press.

UNIVERSITY NOTES.

At the recent Examinations of the University of London, Mr. William Augustus Tilden, Demonstrator in the Laboratory of the Pharmaceutical Society, passed the D.Sc. examination. We see from the official report that a strange mistake has been made in the account given of Dr. Tilden's scientific education, inasmuch as he is stated to have been a student of the Royal College of Chemistry. This was not the case, and as Dr. Tilden is one of the most distinguished students of the School of Pharmacy, we cannot, in justice to the Society, do otherwise than correct the error of the official report of the University of London by stating that he merely attended some of Professor Hofmann's lectures at the Royal College of Chemistry, and that with the exception of private study he received his scientific education in the laboratory of the Pharmaceutical Society at the time when Mr. Allchin occupied the position now held by Dr. Tilden.

The duties of the Vice-Chancellor's office in the University of London, vacated by the death of Mr. Grote, will for the present, it is understood, be discharged by Sir Edward Ryan. The President's chair at University College, vacant from the same cause, is to be filled by Lord Belper. Notwithstanding the alleged increased severity of the matriculation examination at this University, and the large number who have failed in recent years, the number of candidates presenting themselves on the last occasion was larger than in any previous year, being over six hundred.

An offer of £2000 has been made towards the proposed establishment of a chair of applied physics in the Andersonian University at Glasgow, and five scholarships of the yearly value of £50 each, are to be founded in connection with the recently-added chair of technical chemistry. A college of technology, also, is contemplated in Glasgow.

It is announced that upwards of £22,000 of the sum estimated to be required for the College of Physical Science at Newcastle has already been subscribed.

ILLEGAL SALE OF POISONS.

Though we think it desirable that steps should be taken to enforce the provisions of the Pharmacy Act in regard to the sale of poisons, and that persons who persist in disregarding those provisions should be prosecuted in conformity with the Act, it is at the same time highly desirable to avoid any appearance of oppressive application of the law, and that any steps taken with the object stated should be taken upon unquestionably good grounds. We fear that in the case reported at p. 38 this has not been done; for it appears to us more than doubtful whether prussiate of potash comes within the scope of the words "all metallic cyanides." In the first place, this salt is not a cyanide, but a ferrocyanide; then again,—what is still more important,—it is, *de facto*, not a poison any more than cream of tartar is. For this latter reason alone, it should not be comprised by the terms of the schedule; and if those terms be held to include it, it seems equally clear that the schedule needs revision.

A CONFERENCE QUESTION.

The letter published with this title at p. 40, relates to a point which we think should receive attention; and, while we have for that reason suggested to our correspondent that he should communicate with the Local Secretary in Edinburgh, it may not be out of place to express the opinion that the opportunity of promoting "friendly intercourse among those engaged in pharmacy," which is afforded by having a common place of meeting together in the evenings during the Conference meeting, is one of the most valuable features of this annual gathering. We believe also that, quite apart from the agreeable nature of those evening meetings, many members of the Conference share with us the opinion expressed as to their higher utility.

In a recent number of the *Lancet* an opinion is expressed that social gatherings, like the Conversazione of the College of Physicians, the Royal Society, the Pharmaceutical Society, the Society of Arts, etc., might be multiplied with great advantage; and that if professional and scientific men could be more frequently brought together for the purpose of pleasant mutual intercourse,—to examine the latest inventions in science and the latest novelties in connection with their calling, or to chat about politics and things in general affecting them,—jealousies would be softened down, and a wider spirit of charity would grow up amongst them. The Editor of the *Lancet* thinks that this course would be of special service to the medical profession, and we believe it would be equally serviceable to pharmacists.

Since visitors to the Conference will have to reach Edinburgh on the Monday, and will not participate in the advantage given to members of the British Association, as regards the extension of the usual limits of return tickets, we may mention that tourists' return tickets, available for a month, can be obtained at any time. The charges for these tickets are £6. 3*s*. first-class, and £2. 10*s*. third-class.

REPORT OF THE COMMITTEE TO DIRECT THE OPERATIONS OF THE SOCIETY IN COMMUNICATING WITH THE LOCAL SECRETARIES AND MEMBERS UPON THE SUBJECT OF OPPOSING THE BILL INTITULED AN ACT TO AMEND THE PHARMACY ACT, 1868.

The following is tabulated from the returns forwarded by Local Secretaries as to Petitions presented against the Bill. In some instances the number of Chemists and Druggists in the locality has not been supplied.

Proceedings of Scientific Societies.

ROYAL INSTITUTION OF GREAT BRITAIN.

At the General Monthly Meeting on Monday, Sir HENRY HOLLAND, Bart., M.D., D.C.L., F.R.S., President, in the chair, Mr. William Amhurst Tyssen Amhurst, F.S.A., M.R.S.L., and Mr. Lawrence Trent Cave, F.R.G.S., were elected members of the Royal Institution. The special thanks of the members were returned for donations to "the fund for the promotion of experimental researches." The special thanks of the members were returned to the Lord Lindsay for his present of a valuable spectroscope. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

Parliamentary and Law Proceedings.

HOUSE OF LORDS.

PETROLEUM BILL.—*July* 4.—The Petroleum Bill passed through Committee. Petitions against the Bill were presented by the Earl of Carnarvon from—

Birmingham, Merchants at.
Bristol, Oil-merchants at.
Exeter, Merchants and Shipowners at.
Hull, Merchants at.
London, Merchants and Dealers in Petroleum in.
Nottingham, Shipowners at.

HOUSE OF COMMONS.

PHARMACY ACT (1868) AMENDMENT BILL.—*June* 29.—Dr. BREWER gave notice that in Committee on this Bill he would move, in clause 2, page 2, line 1, to leave out from "If at any time" to end of clause.

Petitions against the Bill were presented from—

Alford, by Mr. Chaplin.
Basingstoke, by Mr. Sclater-Booth.
Belfast, by Mr. M'Clure.
Colchester, by Dr. Brewer.
Dorchester, by Colonel Napier Sturt.
Dover, by Major Dickson.
Gravesend, by Sir C. Wingfield.
Greenock, by Mr. Grieve.
Knaresborough, by Mr. Illingworth.
Leith, Portobello, and Musselburgh, by Mr. Macfie.
Lynn, by Mr. Bourke.
Margate, by Mr. G. Milles.
Midland Counties Chemists' Association, by Mr. Dixon.
Montrose and Brechin, by Mr. Baxter.
Newcastle-under-Lyme, by Mr. W. S. Allen.
St. Alban's, by Mr. Abel Smith.
Stamford, by Sir J. Hay.
Truro, by Sir F. M. Williams.
Weston-super-Mare, by Major Allen.
Woburn, by Colonel Gilpin.
Worcester, by Mr. Laslett.
Wrexham, by Sir W. W. Wynn.
York, by Mr. James Lowther.

June 30.—Petitions against the Bill were presented from—

Ambleside, by Mr. Jacob Bright.
Birkenhead, by Mr. Laird.
Carmarthen, by Colonel Stepney.
Chesterfield, by Captain Egerton.
Crosshills, by Lord F. Cavendish.
Deal and Walmer, by Mr. H. A. Brassey.
Doncaster, by Mr. Jacob Bright.
Ealing, Acton, and Hanwell, by Viscount Enfield.
Elgin, by Colonel Grant.
Exeter, by Mr. Bowring.
Falmouth, by Mr. Eastwick.
Flint and Holywell, by Lord R. Grosvenor.
Folkestone, Hythe, and Sandgate, by Baron M. de Rothschild.
Guildford, by Mr. G. Onslow.
Hartlepool and West Hartlepool, by Mr. Ward Jackson.
Haverhill, by Lord A. Hervey.
Kirriemuir, by Mr. Carnegie.
Kirton-in-Lindsey, by Sir M. Cholmeley.
Lewes, by Lord Pelham.
Manchester and Salford, by Mr. Jacob Bright.
Oldham and district, by Mr. Hibbert.
Penrith, by Mr. N. Hodgson.
Ripon, by Sir Henry Storks.
South Shields, by Mr. Stevenson.
Stourport, by Colonel Anson.
Tiverton, by Mr. Denman.

July 3.—In answer to a question from Mr. T. Cave, whether the attention of the Government had been drawn to the numerous petitions that have been presented against the Pharmacy Bill, and whether it was intended to proceed with the Bill during the present session,—

Mr. W. E. Forster said the Government intended to proceed with the Bill during the present session, its object being mainly to ensure that the first clause of the Pharmacy Act, passed in 1868,—which said there should be regulations for the keeping, dispensing and selling of poisons,—should be complied with. He was aware that several petitions had been presented against the Bill from chemists and druggists throughout the country, but he hoped to be allowed to take the second reading on Thursday, with a view afterwards to go into Committee, *pro formâ*, and reprint the Bill with amendments, which, he believed, would meet the wishes of many persons connected with the trade.

Petitions against the Bill were presented from—

Barnsley, by Mr. F. H. Beaumont.
Belper and Ripley, by Mr. R. Smith.
Birmingham and neighbourhood, by Mr. Dixon.
Bristol, by Mr. Morley.
Cardigan, by Sir T. Lloyd.
Leighton Buzzard, by Colonel Gilpin.
Lyme Regis and Axminster, by Mr. Portman.
Market Harborough, by Mr. Pell.
Newtown, by Mr. Hanbury-Tracy.
Otley and Ilkley, by Mr. Denison.
Patrington, by Mr. Broadley.
Perth (County of), by Mr. Parker.
Poole, by Mr. A. E. Guest.
Ryde, by Mr. B. Cochrane.
Shrewsbury, by Mr. Straight.
Southampton, by Mr. G. Gurney.
Stoke-upon-Trent, by Colonel Roden.
Tenby, Narberth, and Saundersfoot, by Mr. T. C. Meyrick.
Warrington, by Mr. Ryland.
Welshpool, by Mr. C. W. W. Wynn.
Whitby, by Mr. W. H. Gladstone.
Windsor, Eton, and Slough, by Mr. Eykyn.

July 4.—Petitions against the Bill were presented from—

Ashford, by Mr. G. Milles.
Banff, Macduff, Porsoy, etc., by Mr. Grant Duff.
Barnet, by Mr. H. R. Brand.
Bromley and neighbourhood, by Mr. Mills.
Cirencester, by Mr. Bathurst.
Edinburgh, by Mr. M'Laren.
Gosport, by Mr. W. F. Cowper-Temple.
Horsham and Crawley, by Mr. Hurst.
Howden, by Mr. Sykes.
Huddersfield, by Mr. Leatham.
Leicester, by Dr. Brewer.
Mansfield, Mansfield Woodhouse and Sutton, by Mr. F. C. Smith.
Merthyr Tydvil and Aberdare, by Mr. Fothergill.
Odiham District, by Mr. G. Sclater-Booth.
Portsmouth, by Sir J. D. Elphinstone.
Ramsgate, by Mr. Pemberton.
Runcorn, by Mr. W. Egerton.
Salisbury, by Dr. Lush.
Tetbury, Northlead and Fairford, by Sir M. Hicks Beach.
Ulverstone and Chorley, by Colonel Wilson Patten.
Watford, by Mr. Cowper.
Westminster, by Mr. W. H. Smith.

July 5.—Petitions were presented against the Bill from—

Bedford, by Mr. Heron.
Bushey and Rickmansworth, by Mr. H. R. Brand.
Kendal, by Mr. W. Lowther.
St. Ives, Camborne, Hayle and Penzance, by Mr. Magniac.
Wolverhampton, by Mr. Villiers.

July 6.—The Pharmacy Act (1868) Amendment Bill.—Mr. W. E. Forster: I beg to move the second reading of this Bill.

Mr. M'Cullagh Torrens: As I understand, it will be convenient that the Government should obtain the assent of the House for reading this Bill a second time to-night (no, no). If honourable gentlemen will favour me with their attention, I think I can satisfactorily explain why it is for the interest of those for whom they, as well as myself, are interested in this matter, that the course I am about to propose should be taken. I understand—in fact, I have reason to know—that the Government intend to bring forward a number of new clauses which may or may not in the estimation of the trade seriously affect their position. I think it is only fair that the country should know what these clauses are before we are called upon to discuss them (hear, hear). I have not the faculty which some honourable members seem to think they have, of being able to discuss clauses before they know what they really are. Having charge of this matter on behalf of a very numerous body of the trade, I am authorized by them to state that they prefer seeing the proposed new clauses before we come to discuss the Bill (hear, hear). If the right honourable gentleman who has charge of the Bill will consent that no discussion shall take place on the merits of the Bill until it is proposed to go into Committee on the measure, I should think, for the benefit of those I so unworthily though sincerely represent, that we should not be called on to discuss it at this hour (quarter past 1 o'clock), which must be left uncompleted, however regularly conducted. The Government having changed their mind on some very important details of the measure, it was but fair that we should know the nature of this altered Bill, and that time should be given (say ten days) for further consideration of the amended Bill by those interested in the country, before we are called on to pronounce an opinion upon it.

Mr. B. Cochrane: I quite concur in what has fallen from the honourable gentleman the member for Finsbury. I know there is a large body of persons in the country who are deeply interested in this Bill.

Mr. W. E. Forster: I have no intention of asking the House to enter on a discussion of the Bill, or to go to a division this evening, but I should be very glad if the House would assent to the course recommended by the honourable gentleman the member for Finsbury (no, no); and for this reason, a great deal of interest is felt in the Bill by gentlemen in the country, who are principally concerned in the progress of the measure. I believe my honourable and learned friend is only speaking the truth when he says that a large number of those gentlemen will be glad to know how the Government propose to meet their objections. If I am allowed to take the second reading I should not consider the House pledged in any way to the merits of the Bill, but that is the only way I can put before them the Amended Bill, and I propose to go into Committee, *pro formâ*, to-morrow or the next day, for the purpose of printing the Amendments (no, no, withdraw). There is no other way by which the views of the Government can be placed before the House, or the members of the trade be informed of the manner in which the Government propose to deal with it (withdraw). I undertake not to discuss the measure until Monday week, and I really will pledge the Government, in the strongest way possible, to allow an opportunity for discussing the Bill.

Sir H. J. Selwin-Ibbetson: I hope the House will not agree to what has been just proposed (hear, hear), and I will state my reasons for it. I am quite aware that the country is very anxious to see any amendments the Government propose to make in the Bill, but I confess I look with some alarm on a practice that is growing up in this House of assenting to the second reading of Bills and affirming principles without discussion (hear, hear). Supposing the Government to be anxious to amend the Bill, and that the country should have the earliest opportunity of knowing what they propose, it was in their power to place the amendments on the paper (hear, hear). They would then become public property and be circulated throughout the country the same way as if the Bill were committed *pro formâ*, and as then corrected, to be sent out. By such a course the House would not be pledged to the principle of a Bill we have not discussed. I hope the House will mark its sense of objection to what I think is a principle too lightly adopted (hear, hear).

Mr. W. E. Forster: Allow me for one moment. My sole object is to get the alterations of the Government brought before the House and the country as soon as possible. Although it is a very unusual course to take to place amendments on the paper before a Bill is read a second time, yet, as it appears to be the wish of the House that it should be done, I will do so (hear, hear).

Dr. Dalrymple: I am sorry to find there appears to be so strong an opposition to the Bill. The principle involved in the Bill being read a second time is as clear as possible, viz. that there is a right to put certain restrictions on the sale of poisons. That these restrictions have not been tested is the fault of the parties themselves; but nothing could be more unfair or unjust than that this Bill should pass as it now stands, and but for the fact that it was to be amended and fully and fairly put before the House and discussed, I should oppose the measure.

Mr. Beresford Hope: I rise to second the statement of the honourable baronet the member for West Essex. I am glad the House has made this protest against reading Bills a second time in the manner now proposed.

Mr. W. E. Forster: I will take the second reading on Monday week.

Petitions were presented against the Bill from—

Bangor and neighbourhood, by Mr. Jones-Parry.
Cheltenham, by Mr. H. B. Samuelson.
Hereford, by Major Arbuthnot.
Liverpool, by Lord Sandon.
Maidenhead, by Mr. Walter.
Manchester Society of Chemists and Druggists, by Mr. Jacob Bright.
Radcliff Bridge, by Mr. Jacob Bright.

In order to afford a ready means of comparing the amendments with the Bill as at first introduced, we reprint them here, together with the original draft and the recommendations lately issued by the Pharmaceutical Society as to the keeping, dispensing and selling of poisons.

AMENDED FORM OF A BILL INTITULED AN ACT TO AMEND THE PHARMACY ACT, 1868.

*** *The amendments are in italics.*

Whereas under the Pharmacy Act, 1868, persons selling or keeping open shop for retailing, dispensing, or compounding poisons are required to conform to such regulations as to the keeping, dispensing, and selling of poisons as may from time to time be prescribed by the Pharmaceutical Society, with the consent of the Privy Council:

And whereas the Pharmaceutical Society have failed to submit for the consent of the Privy Council any regulations for the above purposes, and it is expedient to make further provision for the making of such regulations:

Be it enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows;

1. This Act shall be construed as one with the Pharmacy Act, 1868 (in this Act referred to as the principal Act), and with the Act of the Session of the thirty-second and thirty-third years of the reign of her present Majesty, chapter one hundred and seventeen, intituled "An Act to Amend the Pharmacy Act, 1868," and those Acts and this Act may be cited together as the Pharmacy Acts, 1868 to 1871, and each of the above-mentioned Acts and this Act may be cited as the Pharmacy Act of the year in which it was passed.

2. The recited powers of the Pharmaceutical Society of Great Britain under the principal Act shall cease.

After the first day of October, 1871, *the regulations as to the keeping, dispensing and selling of poisons within the meaning of the principal Act, which are set out in the schedule to this Act, shall be observed by all persons who keep open shop for the retailing, dispensing or compounding of poisons, and shall have the same effect as regulations prescribed in manner specified in the principal Act, and the provisions of the principal Act relating to such regulations shall be construed accordingly.*

Every person who keeps open shop for the retailing, dispensing or compounding of poisons, and fails to conform with any of the said regulations shall, notwithstanding anything contained in section sixteen of the principal Act, or in section one of the Pharmacy Act, 1869, *be liable to a penalty not exceeding in the case of the first offence five pounds, and in the case of a second or any subsequent offence ten pounds, which penalties may be recovered on summary conviction as penalties under the principal Act may be recovered.*

The Council of the Pharmaceutical Society may from time to time, by resolution approved by the Privy Council, revoke, alter and add to the regulations contained in the schedule to this Act, or made in pursuance of this section, and make new regulations in their place; and such resolution so approved shall, on coming into operation, have effect as if it were contained in the schedule to this Act.

Every resolution so approved shall be published in such manner as the Privy Council may direct, and shall come into operation at the date of such publication, or such later date as may be specified in the resolution.

Sections ten and eleven of the principal Act are hereby repealed, and in lieu thereof be it enacted as follows:—

It shall be the duty of the Registrar to make and keep a *correct register, in accordance with the provisions of the principal Act, of all persons who are entitled to be registered under that Act, and to erase the names of all registered persons who have died or ceased to carry on business, and from time to time to make the necessary alterations in the addresses of the persons registered under the principal Act.*

Every registered person shall send by post, by a prepaid letter, to the Registrar, notice of his ceasing to carry on business, and of any change in his address.

To enable the Registrar duly to fulfil the duties imposed upon him, it shall be lawful for him to send by post a prepaid letter to any registered person, addressed to him at his registered address, and enclosing a form to the effect that the person signing the same carries on business at the address therein specified, and requiring such person to return the form, duly filled up and signed, to the Registrar within ten days from the date of the letter, and stating that in default further proceedings will be taken under this section.

If the letter so sent is returned to the Registrar through the dead letter branch of the Post Office, the Registrar may erase from the register the name of the person to whom the same was addressed.

If the letter is not so returned to the Registrar, but no answer is received thereto by the Registrar within three weeks after the date of the same being sent, the Registrar may send by post a prepaid registered letter, addressed as aforesaid, to the like effect as the former letter, but requiring the person to whom it is addressed to send with the form a fee of sixpence, and stating that if he fail to return such form duly filled up and signed, and such fee, his name will be erased from the register.

If the Registrar does not receive the form duly filled up and signed, and such fee, within fourteen days after the last-mentioned letter is sent, the Registrar may erase the name of the person to whom the same was sent from the register.

Any name erased in pursuance of this section may be restored by direction of the Council of the Pharmaceutical Society upon the payment of a fee of ten shillings, but the Council may remit the fee if it appear to them that the person whose name has been erased has, by reason of not having received the registered letter or otherwise, been innocent of any default under this section.

Section fourteen of the principal Act (which relates to the punishing of persons procuring registration by false representations) shall extend to any person who wilfully makes any false statement in any form sent to the Registrar in pursuance of this section, or in any other communication, verbal or written, to the Registrar relative to or to the same effect as such form, and every such person shall be liable to be punished accordingly.

The term "address" of a person in this section means the place at which he carries on business.

Schedule.

Regulations for the Keeping, Dispensing and Selling of Poisons within the meaning of 31 *&* 32 *Vict. c.* 121, *to be observed by persons keeping open shop.*

(1.) *In the keeping of poisons each bottle, vessel, box or package containing a poison shall be labelled with the name of the article, and also with some distinctive mark indicating that it contains poison.*

(2.) *In the keeping of poisons each poison shall be kept on one or other of the following systems, namely :—*

(a) *In a bottle or vessel tied over, capped, locked or otherwise secured, in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop or dispensary; or*

(b) *In a bottle or vessel rendered distinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop or dispensary; or*

(c) *In a bottle, vessel, box or package kept in a room or cupboard set apart for dangerous articles.*

(3.) *In the dispensing or selling of poisons, every bottle or vessel containing an embrocation, lotion or liniment in the composition of which any poison forms a part shall have affixed thereto (in addition to the name of the article and to any particular instructions for its use) a label, giving notice that the contents of the bottle or vessel are not to be taken internally.*

In this schedule "poison" means a poison within the meaning of the "Pharmacy Act, 1868."

ORIGINAL DRAFT OF A BILL INTITULED AN ACT TO AMEND THE PHARMACY ACT, 1868.

*** *The parts amended are in italics.*

Whereas under the Pharmacy Act, 1868, persons selling or keeping open shop for retailing, dispensing or compounding poisons are required to conform to such regulations as to the keeping, dispensing and selling of poisons as may from time to time be prescribed by the Pharmaceutical Society, with the consent of the Privy Council:

And whereas the Pharmaceutical Society have failed to submit for the consent of the Privy Council any regulations for the above purposes, and it is expedient to make further provision for the making of such regulations:

Be it enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in the present Parliament assembled, and by the authority of the same as follows :—

1. This Act shall be construed as one with the Pharmacy Act, 1868 (in this Act referred to as the principal Act), and with the Act of the session of the thirty-second and thirty-third years of the reign of her present Majesty, chapter one hundred and seventeen, intituled "An Act to amend the Pharmacy Act, 1868," and those Acts and this Act may be cited together as the Pharmacy Acts, 1868 to 1871, and each of the above-mentioned Acts and this Act may be cited as the Pharmacy Act of the year in which it was passed.

2. The recited powers of the Pharmaceutical Society of Great Britain under the principal Act shall cease, *and the Council of the said Society may from time to time submit to the Privy Council regulations as to the keeping, dispensing and selling of poisons within the meaning of the principal Act, and as to revoking or amending any such regulations previously made, and the Privy Council may, if they think fit, by order approve of such regulations.*

If at any time it appear to the Privy Council that there are no regulations for the time being in force under the principal Act as to the keeping, dispensing and selling of poisons within the meaning of the principal Act, the Privy Council may serve a notice on the Council of the Pharmaceutical Society requiring them to frame and submit for the approval of the Privy Council regulations as to the matters aforesaid, and if the Council of the Pharmaceutical Society, within the time limited by such notice, not being less than two months from the date of the service of the notice, make default in framing such regulations, or obtaining the approval of the Privy Council thereto, the Privy Council may themselves frame regulations as to the matters aforesaid.

All regulations approved or framed by the Privy Council in pursuance of this section shall have the same effect as regulations prescribed in manner specified in the principal Act.

RECOMMENDATIONS BY THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN FOR THE KEEPING, DISPENSING AND SELLING OF POISONS.

1. *That in the keeping of poisons each bottle, vessel, box, or package containing a poison be labelled with the name of the article, and also with some distinctive mark indicating that it contains poison.*

2. *Also that in the keeping of poisons, each poison be kept on one or other of the following systems, viz.*

(a) *In a bottle or vessel tied over, capped, locked, or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop, or dispensary; or*

(b) *In a bottle or vessel rendered distinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop, or dispensary; or*

(c) *In a bottle, vessel, box, or package kept in a room or cupboard set apart for dangerous articles.*

3. *That in the dispensing and selling of poisons all liniments, embrocations, and lotions containing poison be sent out in bottles rendered distinguishable by touch from ordinary medicine bottles, and that there also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally.*

SPURIOUS TEA.—*July* 3.—Mr. G. Gregory asked the President of the Board of Trade whether his attention had been called to the importation of spurious tea; and whether he had ascertained if the law, as it at present stood, prevented such importation, or provided for the summary condemnation of such tea; and, if it did not, whether he was prepared to propose legislation upon the subject.

Mr. Chichester Fortescue said he had lately received an important deputation on this subject from the sanitary authorities of the City of London, who explained to him the great abuses which occurred in the importation of those spurious teas. They exhibited to him various samples of a very remarkable character—one consisting of matter so decayed that it was offensive to the smell, and another sample containing such a quantity of iron filings that they were visible to the eye by the use of a magnet. There were other specialities of that kind. He had since then inquired into the state of the law, and had reason to think that the Commissioners of Customs had no power to prevent these practices provided that the duty were duly paid. Whether it would be right to give the Commissioners of Customs such powers, which were beyond their usual functions, he was not then prepared to say; but he would undertake to consider the question, and was now in communication with the Chancellor of the Exchequer respecting it.

TWO CHILDREN POISONED BY A WRONG MEDICINE.

On Friday, June 30, Dr. Lankester held an inquest on the bodies of Ada and Arthur Ford, twin children, aged fourteen days, who died from the effects of poison given in mistake for another medicine at the Islington Dispensary. From the evidence it appeared that the two children being somewhat poorly, the nurse in attendance upon Mrs. Ford, the mother of deceased, attended at the dispensary, and having explained how the children were, Mr. Waller, one of the medical officers, prescribed a rhubarb and soda powder to be given, a fourth part to each child occasionally. The powders were administered about half-past eleven o'clock. About two o'clock the mother looked at the children and said she thought one was dead, and the other looked so bad she was sure they were poisoned. She ran to the dispensary for a doctor, and Mr. Waller attended.

Mr. Arthur Waller, surgeon to the Islington Dispensary, deposed that he prescribed a rhubarb and soda powder, as stated, with instructions that they should be divided into four, and a part given to each child. On being sent for on Tuesday he found one child dead and the other dying. On examining the powder he found it was not what he had ordered, but a twenty-grain compound "Kino" powder, containing a quarter of a grain of opium. There was no doubt but the administration of this powder had killed the children. He had made inquiries, and as the drawer in which the powders were kept contained sixteen partitions, he could only account for these powders getting into the wrong place by accident.

Mr. John Levygill, the apothecary at the Dispensary, said he did not recollect the application for a rhubarb and soda powder, but if it were made he gave them what he supposed to be one. As the "Kino" powders were next to the rhubarb and soda, the latter might have got into the wrong compartment. The powders were all in white paper, and there were only labels on each compartment.

Mr. J. T. Glover, surgeon, stated that he had made a *post-mortem* examination of the bodies, and found that the children had been poisoned by opium. The same quantity of opium would have killed a stronger child than either of the deceased.

The jury returned a verdict—"That the deaths had taken place from the effect of an overdose of opium through accidental causes." The jury were, however, also strongly of opinion that were all poisonous powders put in coloured paper, there would be no recurrence of so serious a mistake.—*Daily News*.

DEATH FROM AN OVERDOSE OF CHLORAL HYDRATE.

An inquest was held on Friday, June 14, at Huddersfield, to inquire into the circumstances attending the death of Mr. J. S. Bowman, a commercial traveller. The deceased was stopping at the George Hotel, and on going to bed on Wednesday night had requested that he might be called at seven o'clock the next morning. This was accordingly done, but the deceased did not make his appearance; about two o'clock therefore the door was broken open, when he was found to be lying in the bed quite dead. Evidence was given that he appeared in good health and spirits the night before. In his portmanteau was found a corked bottle containing chloral hydrate. There was a glass found in the room, but it had nothing but a little water in it.

Walter Abraham Grace, of Bradford, said, I am assistant to Mr. F. M. Rimmington, pharmacist and chemist, Bradford. The directions on the bottle produced are in my handwriting. I have just seen the body of deceased, and identify him as being the same person who called at my employer's shop between one and three o'clock on Tuesday afternoon. He asked Mr. Rimmington's son for six doses of the hydrate of chloral, with 30 grains in each dose. Previous to supplying him, I, according to instructions, consulted Mr. Rimmington, who interrogated the man as to his knowledge of the article. The deceased said he was perfectly aware of its properties, and that he was perfectly familiar with it, having taken it many times before. Mr. Rimmington said the deceased's reply was quite satisfactory, and they might have taken him for a medical man, he was so familiar with the article. Mr. Rimmington then came to my dispensing counter and told me I was to make up the mixture. I made up the mixture, and placed it in the bottle now produced. Mr. Rimmington saw me make up the mixture and write a label, but, not being satisfactory, he told me to write another copy. The label contains the words, "The mixture, containing 30 grains chloral hydrate in each ounce, one-sixth part for a dose." The bottle has upon it the scale for the six doses. I wrapped up the bottle, and explained to the deceased personally that one-sixth part contained 30 grains, and, from my recollection, he replied that he was perfectly satisfied, as he understood how to take it, having taken it before. He did not tell me for what specific purpose he wanted the chloral hydrate, nor did he complain of any illness. He seemed quite sober. Thirty grains are below the average dose. I think six or eight doses is quite as much as we should supply at one time, but we should not supply that quantity, unless we knew the man had taken it before, or that he was familiar with its properties.

Mr. Hewby, surgeon, said that he found the body perfectly cold and rigid; the face was congested and the hands were blue. In the absence of a *post-mortem* examination, he thought death had been caused by an overdose of the mixture of chloral hydrate.

The jury returned a verdict that death was caused by an overdose of chloral hydrate, administered by himself without any intention to destroy life.

Selling Poison without a Label.

On Tuesday, July 4, at the Clerkenwell Police Court, William Jackson, of 11, Macclesfield Street North, City Road, was summoned before Mr. Cooke by Inspector James Taylor of the N division, charged as follows: "for that you on the 23rd day of June did unlawfully sell by retail certain poison, to wit, 'prussiate of potash,' without the box, bottle, vessel, wrapper or cover in which such poison was contained being distinctly labelled with the name of the article and the word 'poison,' and with the name and address of the seller, contrary to the statute," etc.

Police-constable Nursey, 251 N, said that the defendant kept a small druggist's shop, and on the day in question he went there and asked to be served with a small quantity of prussiate of potash. He saw the defendant's wife and she went to the back of the shop and fetched the defendant. He said he would not let him have what he wanted, because he had got in trouble a short time before for selling poison. He had been given to understand that the defendant was a bricklayer by trade.

Mr. Thomas Shaw, a licentiate of the Apothecaries' Society of London, and registered, in answer to Mr. Cooke, said that prussiate of potash was a metallic cyanide and a poison.

Inspector Taylor said that these proceedings were taken owing to a man having poisoned himself with arsenic that had been purchased at defendant's shop.

The defendant, in reply to the charge, said that the constable, when he entered, was in his shirt sleeves, and saying that he was a shoemaker, asked for the stuff in the regular course of trade. He had that morning purchased one pennyworth of the same stuff without there being any label on it. It could be purchased at any oil shop in London, and more especially in St. Luke's.

Mr. Cooke said that did not justify the defendant in acting as he had done. The Act under which these proceedings were taken was passed expressly to regulate the sale of poison, and the defendant might have been charged with two offences, for the poison the defendant had sold was classed in schedule A of the Act. The defendant had committed an offence by selling that poison to any person whom he did not know, or who was introduced by some one he did not know. The only charge he had to deal with was the one before him, but the fact that a man had poisoned himself with poison that had been purchased at the defendant's shop only showed how important it was that the provisions of the Act should be fully carried out. He should have to make an example of the defendant for the sake of the public good, and should order him to pay a fine of £3 and the costs, or in default six weeks' imprisonment in the House of Correction. The defendant was removed in custody.—*Clerkenwell News.*

[*** The person prosecuted in this case was the owner of the shop referred to in the report of a case of poisoning by arsenic which was illegally sold at that shop. (See Vol. I., 3rd Ser., p. 1000.)—Ed. Ph. Journ.]

Notes and Queries.

NOTICE.—*To prevent delay, correspondents are requested to send their communications to the Journal Department,* 17, *Bloomsbury Square, W.C., and not to the Publishers.*

EMPLASTRUM VESICANS MEDIOLANENSIS. Milanese Flies (Mouches de Milan):—

Burgundy Pitch, purified,
Yellow Wax,
Spanish Flies, powdered, of each 50 grammes.
White Turpentine, 10 grammes.
Oil of Lavender,
Oil of Thyme, of each, 1 gramme.

Melt the two first substances together, add the flies and digest over a water-bath for two hours, after which add the turpentine, and when that is dissolved, remove the vessel from the fire, taking care to stir continually till the mass is half cooled down, then aromatize with the volatile oils.

When specially indicated, dispense this plaster divided into small flattened balls weighing one gramme, wrapped into a piece of black taffeta 6 centimetres ($2\frac{3}{8}$ in.) in diameter, folded upon itself. The plaster is spread out upon this when used.

This elegant form of dispensing empl. cantharid. is common in France, although it is one of those preparations, the keeping on hand of which is not made obligatory on French apothecaries by their Pharmacopœia.—*American Pharmacist.*

CHLORAL HYDRATE AND COD-LIVER OIL.—The *Gaz. Farm. Ital.* advocates the addition of chloral-hydrate to cod-liver oil; it renders it much less nauseous, and prevents the night sweats of the phthisical patient, induces sleep, and creates appetite. It is prepared as follows:—

10 gr. pure chloral-hydrate crystals with 190 gr. cod-liver oil, digested in a sand-bath with gentle heat. Dose, six tablespoonfuls daily.

[266.]—SYRUPUS QUINIÆ ET MORPHIÆ BROMIDI.—*F. J. H.* asks for a formula for Syrupus quiniæ et morphiæ bromidi (Dr. B. W. Richardson's).

[267.]—LEMONADE POWDERS.—*A.* and *B.* will be obliged to any one who will favour them with a good formula.

[268.]—VARNISH FOR PILLS,—Would some of your readers be good enough to furnish me with a good recipe for varnishing pills to *shine* well. I have not found the usual process satisfactory.—J. T. Abbott.

[269.]—REMOVAL OF COFFEE STAINS.—*E. H. C.* would be obliged if any one would inform him how to remove coffee stains from a book; the paper is unglazed, of a rather common quality and slight blue shade.

[270.]—CEMENT FOR CORK.—Can any reader inform me of a substance that may be used for gumming strips of cork to bottle stoppers which will not give way like gum arabic when wet? or a composition that may be used for the same purpose?—J. S.

[271.]—DISPENSING.—*A. B. C.* asks how he can prepare from the annexed prescription a perfectly white creamy liniment which will not separate?

℞. Acid. Acet. fort. ʒss
Vitell. Ovi j
Ol. Terebinth.,
Aquæ, ana ℥iij.
M. ft. linim.

[272.]—SUPPOSITORIES.—Will one of the readers of the PHARMACEUTICAL JOURNAL oblige me with the best formula for a basis for belladonna, opium and camphor suppositories?—C.

POISON BOTTLES.

Sir,—Much has been said and written at various times in favour of our poisons being safe if kept in bottles of peculiar colours. Some gentlemen have also recommended a piece of sandpaper being placed on the back of the bottle, and others have strongly advised the use of fluted, spiked and angular bottles. Now, these may all be useful, but I do not consider any of them complete, because the sense of sight and touch would soon be familiar with them. When a man is distressed by too much, or, what is worse, by too little business, by long and anxious hours, by domestic and many other afflictions, he requires something more than either of the above bottles to arrest his attention should he unhappily become so distracted as to place his hand on the wrong one. He must have a physical difficulty in his way to arouse him to the fact that he is about committing a mistake, which may prove fatal to the person to whom the medicine is to be administered, as well as ruinous to himself. And this may be done by means of a very simple and inexpensive contrivance, and one which will create scarcely any delay in dispensing poisons. It is simply bands of india-rubber, arranged like the wire of a sodawater-bottle,—a collar embracing the neck of the bottle,—and attached to this a cross-band passing over the stopper, so that the stopper cannot be removed without pushing the cross-band off. And this arrangement would answer equally well for extracts, pots and jars; and if the cross-band had a loop at each extremity a suitable string might be substituted for the india-rubber collar, thus saving expense.

I should have suggested to the Society the above plan some time since, but something of the kind having been mentioned in the Journal, I thought it might be generally noticed and adopted.

Curtain Road, E.C., J. R. SUMMERS.
June 28th, 1871.

N.B.—The india-rubber bands might, of course, be applied to any of the new poison bottles.

[*** We believe that Messrs. Maw, Son and Thompson are at present engaged in bringing out a fastening for poison bottles very similar, so far as we can judge, to the arrangement described above.—ED. PHARM. JOURN.]

POISON SAFETY.

Sir,—So much having been written of late respecting the storage, etc. of poisons, one feels somewhat reluctant in throwing out any further suggestion; still, as something will ere long be thrust upon us in reference to the keeping, as well as the dispensing and selling of poisons, whether we, as chemists, like it or no,—I have been induced to suggest what appears to me a very simple, and at the same time a very efficient poison safety, viz. that over the cork or stopper, and also to slip over the neck of every bottle, etc., containing any of the poisons enumerated in schedule A, part 1, of Pharmacy Act, 1868, be placed a RED india-rubber capsule, with rim at bottom, similar to Maw's india-rubber teats, used for feeding-bottles. And that over the stoppers, etc., of bottles containing poisons described in schedule A, part 2, be placed a BLACK india-rubber capsule, thus distinguishing at a glance schedule A, part 1 from part 2. These capsules would be manufactured at a cheap rate, last a considerable time, be easily placed upon, or removed from, the bottles, etc., and obviate the necessity of untying and re-tying every bottle required for use, and I believe might admit of universal adoption.

East Southsea, 22nd June, 1871. F. W. WHEELER.

[*** The capsules proposed by our correspondent would seem to be essentially the same as those introduced by Mr. Baildon, of Edinburgh. They were exhibited by him at the Liverpool meeting of the Conference. See Vol. I. 3rd ser. p. 120.—ED. PHARM. JOURN.]

A Conference Question.

Sir,—The many and varied attractions of Edinburgh and its neighbourhood will doubtless be sufficient to induce many pharmacists to attend the meeting of the Conference in August next.

All those who know the kind feeling prevalent on the other side of the border are fully persuaded that everything which can be done to ensure the success of the meeting, and add to the comfort of the visitors, will meet with the attention of their Edinburgh brethren.

In looking through the prospectus recently forwarded to the members with the invitation to the Conversazione, one cannot help noticing the absence of an arrangement made upon previous occasions with the best results, and to which the unprecedented success of the Liverpool meeting of last year was mainly due.

It is said "that information will be given concerning hotel accommodation."

Would it not be much better to make a special arrangement with a first-class hotel to provide for such a number as would in all probability be present?

The members, then, instead of passing their evenings in small groups in the various hotels of the city, would be enabled to join together in those friendly greetings for which pharmacists when abroad are noted, and thereby carry away with them many pleasant recollections of their last merry meeting. A Conference Man.

[We are unable to add anything further to the circular which has been issued, but we would suggest that our correspondent should communicate with the Local Secretary in Edinburgh.—Ed. Pharm. Journ.]

Druggists' Prices North of the Tweed.

Sir,—If my remarks on the Scotch price list had called forth any reply, I fully expected that it would have taken the form of a challenge, to prove the northern origin of the list in question.

Happily, however, I am relieved from what would, under the circumstances, have been a somewhat difficult task, two correspondents from the North having come forward, the one to repudiate, on behalf of the Glasgow Association, the unique production, the other to avow and defend the anonymous emanation from "your committee."

Admitting my oversight of the note, "All prices exclusive of bottles," in this list, my statement holds none the less good, that fourpence is there entertained as an adequate price for a ℥j mixture (as a rule eight doses of medicine), and so on in proportion through a great part of the dispensing portion. The retail portion is, as I suppose, a more dignified department, made vastly more remunerative.

For admirably-planned dispensing price lists, commend me to those bearing respectively the names of the Manchester and Bath Chemists' Associations, each of which, being based upon a moderately-elevated view of the profession of pharmacy, entertain not fourpence (?) but one shilling as the lowest fee for dispensing a bottle of medicine.

Great efforts will be required to effect anything like a general augmentation of the wretched pittance routine and petty rivalry have assigned the chemist as the price of his labour; and those who look forward to such a consummation will, on inspecting the result of the labours of our Northern reformers (?), find it difficult to repress the exclamation, "Save us from our friends!"

Bradford, June 13th, 1871. R. G. H.

The New Pharmacy Bill.

Sir,—The days of class legislation and protection are virtually ended. The policy of Government is to legislate for the many, regardless of the interests of the few. It is in this spirit that the Bills lately introduced, and still before Parliament, have been framed. The Poisons Bill, it is said, is "intended to protect the lives and health of the public," who, it is also stated, are "supremely indifferent to the subject." The same attitude was assumed in respect of the matchless match-box measure, which, had it not met with a decided condemnation, would have now become a vexatious and unjust law. The axiom "men are but sorry witnesses in their own cause," receives a quiet illustration in the department of the governing powers, and there can be little doubt that a poison Bill of some sort will, ere long, be produced and carried into operation, notwithstanding the objections of 10,000 chemists and druggists.

The only cogent argument that is likely to produce any effect is, that the public are not uninterested spectators of the conflict. I believe that were the following address got up and laid upon the counter of every chemist and druggist in the kingdom, it would be signed by every one of our customers, from the greatest to the smallest, producing an aggregate of signatures amounting to, not tens, but hundreds of thousands, whose confidence in the skill and care of their chemists remains unshaken; and who would not wish to see an intelligent class degraded to the level of publicans, cab-drivers and marine-store dealers.

R. Goodwin Mumbray.

Richmond, S.W., June 27th, 1871.

Proposed Form of Address.

To——.

We, the undersigned, inhabitants of ——, regard with aversion any attempt to interfere with the business of chemists and druggists, as now carried on in these realms, believing that as a body of intelligent men, they possess not only the right, but the ability conscientiously to discharge the duties connected with the sale and art of dispensing medicines of any kind whatsoever, to the safety and advantage of her Majesty's subjects. And etc. etc.

"A Drumstick."—We must refer you to the rule concerning anonymous contributions.

"Ignotus" is recommended to consult a good work on arithmetic.

"Spes."—The question has been answered recently in the "Notes and Queries" column.

R. H. C. N.—You would have to pass the Preliminary Examination.

M. P. C.—We have handed your note to the Board of Examiners, where it will produce more effect than in our pages.

R. O.—It would seem that you must have had some impurity in your ingredients or in the water used.

H. Oldfield.—Legally, we believe, a sweet-wine licence would be necessary, though there may be some uncertainty on the point.

X. Y. Z.—The following formula is given by Squire:—Precipitated Chalk, 1; Spermaceti Ointment, 4; mix.

Botanist—The plant forwarded is *Polygala vulgaris*, with blue and white flowers.

Phyto.—The specimen sent is correctly named by you. We know nothing of the occurrence of *Muscari comosum*.

R. Manlove.—The specimen is very bad, but it is certainly not *Chrysosplenium oppositifolium*. It appears to be *Saxifraga tridactylites*.

"An Old M. P. S."—See an article on the Adulteration of Oils, by Mr. F. C. Calvert, Pharm. Journ. 1st Ser. Vol. XIII. p. 356.

"J. S."—In a case recently reported in this Journal (3rd Ser. Vol. I. p. 775), the Bench held that all tooth-powders came within the meaning of the Act as patent medicines.

T. Cooper.—See a paper by Professor Abel in the Pharm. Journ. 1st Ser. Vol. XVII. p. 556, for methods of treating the suspected paper-hanging, after which, if arsenic be present, it may be detected in the usual manner.

Pilula.—Use manna or the following paste:—

Tragacanth	ʒss	
Glycerine	ʒij	Misce.

A. C. Coles.—You will find a formula for syr. ferri hypophosph. in Pharm. Journ. 2nd ser. Vol. IX. p. 461. Syr. sodæ hypophosph. 3 grs. to the drachm. We do not know that the physician referred to has any special form.

Communications, Letters, etc., have been received from Mr. C. Inch, Mr. P. Squire, Mr. F. M. Rimmington, Mr. G. Brown, Mr. Abbot, Mr. B. Keen, Mr. J. Booth, Mr. R. D. Mitchell, Mr. H. Pocklington, Mr. J. Birt, Mr. R. Palmer, Mr. L. T. Ashwell, A. M., J. S., W. H. B., S. W. N., A. W., "Calyx," "Beta," "Chemicus."

MATCHES.

BY B. S. PROCTOR.

(Concluded from page 21.)

About the beginning of the nineteenth century chlorate of potash, with its wonderful oxygen-yielding power, came to the aid of the match manufacturer, and small sulphur matches, with a tip of chlorate and sugar, were ignited by touching them against the stopper of a phial of oil of vitriol. The matches were usually sold in tin boxes, with a division to hold the phial of acid, the whole being known as a chemical fire-box. Several accidents occurred from leakage of the acid, and consequent ignition of the whole boxful of matches, until the expedient was adopted of putting asbestos into the phial, and only so much acid upon it as it would absorb.

One of these old boxes is labelled thus:—

"WITHOUT PHOSPHORUS.
WATTS'
IMPROVED FIRE BOX
FOR OBTAINING IMMEDIATE
LIGHT.

Directions.—Dip the match sharply into the bottle, and instantly withdraw it.

Anderson's Place, Cornwall Road, London."

The bottle was supplied with asbestos, the chemist being expected to add the oil of vitriol at the time of sale. Matches, upon a modification of the same principle, were afterwards introduced under the name of Prometheans. They consisted of spiral cones of waxed paper, with a drop of a pasty mass of moist chlorate of potash and sugar inserted into the open end of the cone, and immersed in this mass a capillary glass tube, in which a very small portion of oil of vitriol was hermetically sealed. When dry, the match could be ignited by striking the end with any hard body, so as to break the tube, and thus bring the acid in contact with the chlorate. These matches were introduced by a Mr. Jones, of the Strand. They were usually sold in hard turned-wood boxes, and were ignited by holding the tip of the match upon the table and striking it with the bottom of the box. They were, in many respects, very good matches, but were necessarily expensive, being sold (to within the last twenty-five years) at 2*s.* 6*d.* per hundred. They are very permanent; some, which are now more than twenty-five years old, igniting as well as when new.

Besides chlorate of potash and sugar, sulphide of antimony sometimes entered into the composition used in tipping matches for chemical fire-boxes, and it was no doubt a compound of that nature, the precise materials of which, however, I have not been able to ascertain, which led to the production of the friction match, which was first made by Mr. Walker, chemist and druggist, of Stockton, in 1827. He had been making a composition for tipping matches to be used with oil of vitriol. Having stirred the same with a slip of wood, some of the composition adhered to it; this, when dry, he accidentally ignited by striking it against the hearthstone. Thus, a happy accident suggested to him the practicability of making matches which should ignite by friction without the use of oil of vitriol. His matches consisted of thin slips of wood about two inches and a half long and about the thickness of cardboard tipped with his newly-discovered composition.* They were sold in cardboard boxes, containing fifty matches, and a piece of sand-paper for igniting them, the price being a shilling. The sand-paper was folded with the rough surfaces inwards, and the match was ignited by placing the tip between these rough surfaces, and suddenly withdrawing it, while gentle pressure was applied. It is said that Mr. Walker paid three-halfpence apiece for the empty boxes, which were made for him by a bookbinder in Stockton. As this was a very important step in advance, and made by a pharmacist, we may not inappropriately quote the following notices of him.

In Richmond's local records of Stockton and neighbourhood, occurs the following:—

"May, 1, 1857. Died at Stockton, Mr. John Walker, aged 78. He was for many years a druggist at that place, and was the inventor of friction matches, the sale of which he commenced in April, 1827, charging one shilling per box, each box containing fifty lucifers."

A correspondent in the *Newcastle Daily Chronicle* supplies the following from the London *Atlas* newspaper of January 10, 1830, headed "Instantaneous Light":—

"Amongst the different methods invented for obtaining a light instantaneously ought certainly to be recorded that of Mr. Walker, chemist, Stockton-on-Tees. He supplies the purchaser with prepared matches, which are put into tin boxes, but are not liable to change in the atmosphere, and also with a piece of fine glass-paper folded in two. Even a strong blow will not inflame the matches, because of the softness of the wood underneath, nor does rubbing upon wood or any common substance produce any effect except that of spoiling the match; but when one is pinched between the folds of the glass-paper, and suddenly drawn out, it is instantly inflamed. Mr. Walker does not make them for extensive sale, but only to supply the small demand in his own neighbourhood."

"The above," adds the same writer, "is placed under 'Scientific Notices,' and we thus gain a glimpse of the first introduction of lucifer matches to supersede the flint, steel, and tinder-box process. In 1830, and for many years previous, Mr. Walker occupied a small shop at the corner of Dovecot Street, Stockton, and is well remembered in the locality as a gentleman of the old school, dressed in drab breeches and gaiters, and always sporting a particularly clean white apron. Mr. Walker afterwards removed to larger and more prominent premises in the High Street, being next door to Mr. Thomas Jennett, printer. In 1830 these matches were sold at half-a-crown per box, and remained for some time at the above price; but as the demand increased the cost was reduced, and sixpence per box was considered a moderate charge for many years. Those who professed to be 'knowing' upon the subject declared old Walker made a handsome thing out of the discovery, inasmuch as he kept the secret of manufacture as long as possible to himself."

These matches, the tips of which were composed of sulphide of antimony and chlorate of potash,

* Probably it consisted of two parts of sulphide of antimony and one of chlorate of potash made into paste with gum water, this being the composition known to be in use a short time afterwards.

required so much friction for their ignition, that the tips were frequently pulled off or worn off before the match took fire, a fault which was remedied some six or seven years later by the use of phosphorus.

Dr. Moldenhauer and Dr. Boettger are spoken of as amongst the most successful workers in the production of phosphorus matches, the composition used by the latter being as follows:—

	Parts.
Phosphorus	4
Nitre	10
Glue	6
Red Lead	5
Smalt	2

The glue being softened with water, and melted in a warm mortar, the phosphorus was stirred in somewhat in the manner of making an emulsion, the temperature used being (140° F.) a few degrees above the melting-point of phosphorus (108° F.). When these were thoroughly mixed, the nitre and colours were added, and a soft, uniform paste produced, with which the matches were tipped after having been first tipped with sulphur.

Phosphorus does not readily communicate its combustion to wood, probably on account of the phosphoric acid produced condensing upon and protecting carbonaceous or fixed materials from the action of the air; thus arises the necessity for the use of sulphur or some other volatilizable substance which is rendered gaseous and ignited by the heat of the burning phosphorus, and can readily communicate its combustion to the wood.

To avoid the unpleasant smell of sulphurous acid, the sulphur was replaced by wax or stearine in the better qualities of matches; the mode of impregnating the tips of the splints with these substances being to press the end of a bundle of them upon a hot iron plate till the wood began to char, and dipping them while thus heated into a tray of melted wax. Camphor was added to the wax by Mr. Bell.

In 1861, Mr. Letchford patented the use of paraffin for the same purpose, the object being to find a material capable of attaining this end, and sufficiently cheap to be used to the common descriptions of matches.

Chlorate of potash, which was indispensable in the early forms both of dipping and friction matches, was not only not essential, but in some respects disadvantageous in union with phosphorus. Nitrate of potash was found to give a quieter and less explosive combustion. The ease with which the phosphorus compounds ignited enabled manufacturers to use soft materials, which would not have borne the rough usage to which Mr. Walker's original friction matches were necessarily subjected. Thus, wax vestas and fusees of soft brown paper, or amadou impregnated with nitrate of potash, were added to the growing number of varieties.

After the use of phosphorus had been considerably developed, it was found that the operatives exposed to its vapours were frequently attacked with painful swellings and inflammation of the lower jaw, sometimes resulting in mortification and exfoliation of the bone. The disease was known as phosphonecrosis. Though a careful attention to cleanliness and ventilation is enough to prevent the occurrence of this malady, there is no doubt that the great suffering it had inflicted upon some of the workpeople acted as one of the inducements to adopt amorphous phosphorus, when that body was made known by Schrotter. He exposed phosphorus, in closed vessels, to a temperature of about 500° F., and found that it was changed in many of its most prominent qualities. It had become opaque, and of a dark red colour; it had ceased to be volatile and fusible; it had lost its tendencies to undergo slow combustion at low temperatures, and was no longer poisonous. But while it had lost many of the objectionable qualities possessed by phosphorus in its ordinary condition, it had also lost some of the qualities which gave phosphorus an advantage over other materials for match-manufacture,—matches of amorphous phosphorus being more difficult to ignite and burning with a sputtering flame, which qualities have hitherto prevented their coming into general use.

But Dr. Boettger, who had devoted much attention to the improvement of match manufacture, suggested in 1848 that the amorphous phosphorus might be made into a friction surface, to be used for igniting matches, tipped with a chlorate compound not capable of ignition by simple rubbing upon an ordinary rough surface. Attempts to carry out this suggestion were made with partial success by various German and French manufacturers during the years 1854 and 1855; but it was not till Messrs. Bryant and May, in August, 1855, patented a modification of this principle that these "safety matches" attained any popularity in England.

Another form of safety match was introduced in 1859 by Messrs. Devilliers and Dalemagne. Each match was tipped at both ends, one end having the chlorate and the other the amorphous phosphorus, and to ignite them the match was broken in two, and one end rubbed against the other,—an arrangement more fanciful than advantageous.

The consumption of matches has increased enormously since the facilities for their production led to a reduction in their price. About five-and-twenty years ago a witty dealer adopted for his placard the lines at the head of this paper:—

"O, Lucifer! how art thou fallen!
Only one penny per box!"

Lucifer has continued to fall ever since, and yet we may say almost all varieties of lucifers are above the price of rubies—Bryant and May's "Rubies;" red-tipped matches of a very cheap quality, being sold at 2*s.* 6*d.* per gross of boxes. This price, low as it is, is not more surprising than the great number produced,—the above firm making daily no less than 1250 gross of boxes of this quality alone, that is about thirteen millions of matches per day.

It might be supposed that, with so great a production and so small a price, there was not scope for further progress in this manufacture; yet the very magnitude of the craft gives a prospect of ample remuneration to any one who can devise an improvement in the quality or greater economy in any department of the work. Various suggestions have been made which have not yet been carried out, but some of which will no doubt afford a handsome profit to any one, be he chemist or manipulator, who finds the means of making them practically available. For example, the proportion of phosphorus formerly used was about one-seventh of the tipping composition, but has been considerably reduced by being more finely divided; and it is said that, by dissolving the phosphorus in bisulphide of carbon, it may be reduced to $\frac{1}{300}$th of the quantity now commonly employed; and Wiederhold has shown that, in the experimental scale at least, good matches may be made with chlorate of potash and hyposulphite of lead, without the use of phosphorus at all.

TESTING PETROLEUM.

BY PROFESSOR ATTFIELD.

In ascertaining the temperature to which a specimen of petroleum must be warmed before its vapour can be ignited, different experimenters obtain different results. The fact is this "flashing-point" varies according to circumstances; unless, therefore, two operators work under exactly similar conditions, their reports will not coincide. In the British Petroleum Act of 1868 somewhat minute directions for applying the flashing test to samples of petroleum are given in a schedule. As originally drawn up, those directions were supplied to the Government by Mr. Abel, Dr. Letheby and myself, and related to the testing of the liquid when contained in a three-inch half-filled cup. After they left our hands, they were made to apply to petroleum contained in a two-inch full cup; the protection from draughts afforded to the surface of the liquid by the upper part of the half-filled cup being substituted by that of a screen so placed round the full cup, that the efficiency of the original directions should not be affected. That is to say, a sample of petroleum flashing at 100° in the unscreened half-filled cup should flash at 100° in the screened full cup. This should be borne in mind by all persons testing petroleum, as the screen can be so constructed or so arranged as to cause flashing-points to be above or below the standard now given. Just before the Act passed, I pointed out to the Government that the alteration would lead to endless disputes, and was assured by letter (which I still possess) that the construction of the apparatus was only varied in a point of detail to meet an objection; that, in short, the screen was to be so efficiently disposed as not to interfere with the standard previously fixed. I may add that one year later (June 1869) in a Bill for consolidating and amending the Petroleum Acts of 1862 and 1868, this standard was maintained with the concurrence of the wholesale and retail petroleum traders, a *covered* screen (which gives results similar to those obtained in the half-filled cup) being directed to be employed. It is to be hoped that this standard, which has been accepted by all parties interested in the sale of mineral oils, will rigidly be adhered to in any attempt at further legislation respecting these liquids. In a Bill now (June 1871) before Parliament, the oils are directed to be tested in a *covered cup*, and the defining clause describes "petroleum" as being a certain liquid giving off inflammable vapour below 85° Fahrenheit. It is to be expected that this is the exact equivalent of the foregoing standard—that petroleum flashing at 85° in the closed vessel would flash at 100° in the open vessel. If not, one section or other of oil traders will probably prevent the maturation of the Bill; a result to be avoided if possible, for fresh legislation is sorely needed. My own testing apparatus is so constructed as to give results such as just indicated, results which I believe to be in exact accordance with the intentions of the Legislature. I may state, shortly, that it is a modification of what is known in trade as "Miles's instrument," with a screen five inches high; no cover to the screen, and with the front third of the smoke-holes of the outer casing permanently closed. The removal of the cover of the screen produces no difference in the flashing-point of a sample of petroleum, the walls of the screen being sufficiently high to protect the cup from draughts in an ordinary room; still I operate without it, to avoid objections that might be raised against the apparatus in a court of law, no special mention of a cover to the screen being made in the Petroleum Act (1868). I close up the front "smoke-holes" (as I have called the holes through which escape the products of combustion of the flame that heats the water-bath), in order to avoid a slight inconstancy of results caused possibly by draughts from these apertures. Miles's instrument, as sold to the public, gives results which are close to those I obtain by the slight modification I have described but the latter gives me those results with greater constancy and certainty.

CLEARING NUTS.

(*Strychnos potatorum.*)

BY M. C. COOKE, M.A.

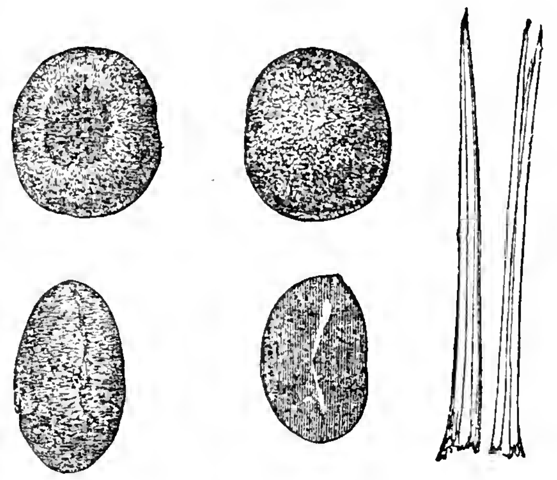
The clearing nuts of India are the produce of a tree which is described as larger than that of the nux vomica. It is without thorns or tendrils; leaves very shortly petioled, elliptic, acute, glabrous, membranaceous, five- and almost penninerved; corymbs axillary, opposite, shorter than the leaf; corolla hirsute within; berry one-seeded; flowers greenish-yellow, fragrant. It is found on the Coromandel coast, the Concans and the western Ghauts, flowering in April.

The native names given by Moodeen Sheriff are,—*Nirmali*, Hindustani, Bengali and Gujerati; *Chilbinj*, Dukhni; *Tetran Kottai*, Tamul; *Chilla-gingalu*, Telugu; and *Tetran-parala*, Malayalim.

The fruit, says Ainslie, when very young, is made into a preserve and eaten, but is reckoned, in its mature state, amongst the emetics of the Tamul doctors of southern India, given in powder in the quantity of about half a teaspoonful. The dried seeds are used for the purpose of clearing muddy water, one of them being usually rubbed hard for a short time round the inside of the earthen pot; the water is afterwards poured into it, and left to settle. The impurities soon subsiding, the water will be found clear, tasteless, and wholesome. Roxburgh adds that the natives never drink clear well-water if they can get pond or river water, which is always more or less impure, according to circumstances. These seeds are therefore constantly carried about by the more provident part of our officers and soldiers in time of war, to enable them to purify their water. They are easier obtained than alum, and probably less hurtful.

The tree grows to a larger size than the nux vomica, and is not so common, being only found amongst mountains and woods of great extent, flowering during the hot season. The berry is shining, and black when ripe, containing only one seed, whereas that of nux vomica is many-seeded. (See

Pharm. Journ. 1st ser. Vol. IX.) Roxburgh says that the wood is hard and durable, and is used for various economical purposes. The seed is broadly lenticular, about half an inch in diameter and a quarter of an inch in thickness; of a dirty whitish-grey colour, and covered with a thick coating of delicate appressed hairs. These hairs are in bundles of from three to six, agglutinated together longitudinally; but when separated each hair is seen to be a simple, pointed, cylindrical cell. To the naked eye, the surface of the seeds appears to be mealy rather than hairy.



Seeds of *Strychnos potatorum*, nat. size; hairs magnified 60 diameters.

The seeds in powder, mixed with honey, are applied to boils to hasten suppuration; also with milk in sore eyes. When used as an emetic in southern India, the seeds are given in powder. Dr. Kirkpatrick says that the seeds are employed as a remedy in diabetes; and they are mentioned in the Taleef Shereef as useful in gonorrhœa, etc. Their chief use, however, consists in their application to the clearing of muddy water.

Dr. Pereira* suggested that the peculiar property of these seeds depends "on the presence of albumen and casein in the seeds, which act as fining agents, like those employed for wine and beer. If the seeds be sliced, and digested in water, a thick mucilaginous, ropy liquid is obtained, which, when boiled, yields a coagulum. If this be removed, a further coagulum is obtained by the addition of acetic acid. These reactions show the presence of albumen and casein." Dr. O'Shaughnessy suggested that the clearing action depends on astringency in the fruit, which Dr. Pereira considers insufficient.

Other seeds are employed in other countries for like purposes; and Niebuhr states, in his 'Travels through Arabia,' that the inhabitants of Cairo, in Egypt, render the muddy water of the Nile quite clear by rubbing bitter almonds, prepared in a particular manner, on the inside of the earthen jars in which the water is kept.

It is not so much the seed as the pericarp that commends itself to our notice. The former is not employed medicinally, whilst the latter is in common use amongst the natives as an emetic.

The use of the fruit as an emetic seems to have been wholly confined to the native practitioners. It has been supposed that the reason why it has never acquired repute is the improper way in which it is administered. The whole fruit is generally powdered, and given in about half a teaspoonful doses. It is not surprising, therefore, that failure should take place, since the large seeds are not emetic, the dry pulp of the fruit and the pericarp alone possessing that property. If these are used separately, the result is said to be very satisfactory.

When sold separately, the emetic portion of the fruit is found in the bazaars in two conditions. In one condition it is in thin, scaly, and shell-like pieces, which are shining externally, and of a greenish- or yellowish-brown colour. This is the pericarp removed when the fruit is dry. In the other condition it is formed together with the mucus into large balls or masses weighing about one pound. In this condition it contains a large quantity of dry mucus, and is much superior in action to the other form. Mr. Moodeen Sheriff states that the dry mucus appears to be more efficacious in dysentery than ipecacuanha.

The dose of the simple powder of the pericarp, prepared in the usual way, and kept in a stoppered bottle, is from 40 to 50 grains as an emetic, and from 15 to 30 in dysentery.

[N.B.—This article was in type before that quoted from the *American Journal of Pharmacy* at p. 23 had appeared; but its publication had been delayed on account of the woodcut.—Ed. Pharm. Journ.]

FLUID EXTRACTS AND THEIR MENSTRUA.

BY EDWARD R. SQUIBB, M.D.

(*Continued from page* 25.)

This process of repercolation has been described in previous papers, but it may be useful here to offer a table of examples, carried out to an exaggerated extent, to exhibit its scope and capacity; and yellow cinchona, dandelion, and senna are selected for illustration. All these drugs were taken in the very fine powders as met with in the markets. One Pharmacopœia portion of 7680 grains of each was taken for each percolation, and three percolations of each drug were made. The percolate from the first portion of each was taken to moisten and percolate the second, and the percolate from the second portion of each was taken to moisten and percolate the third.

The menstruum used for yellow cinchona was a mixture of one part, by weight, of glycerine, and three parts, by weight, of stronger alcohol. That used for the senna was diluted alcohol, and that used for the dandelion was a mixture of equal weights of stronger alcohol and water. The yellow cinchona and dandelion were each moistened with 8 f℥, of menstruum and percolate, and the senna with 9 f℥. All the moistened powders were passed through a sieve before packing, and were packed and managed alike, each pint as it came from one funnel being poured on top of the other.

It will be seen by reference to the first table that it is estimated that the Pharmacopœia *may* get in yellow cinchona 55 per cent. of the extract from the bark, or 866 grains in the two pints. By the last cinchona column of the table of repercolations it will be seen that if the first four pints from the third portion be mixed together, each pint of the mixture will contain almost as much extract of cinchona as the officinal two pints, and the whole four pints will make, by adding the next four pints of the column, eight pints, having nearly the strength of the officinal preparation, and this from three portions of powder.

If the fluid extract of cinchona be changed in the new Pharmacopœia to double the present officinal strength, and the standard for percolation be unchanged, then this column would yield about $2\frac{1}{2}$ pints of double the present officinal strength. But if the standard be increased so that the preparation shall contain 80 per cent. of the extract, or 1244 instead of 866 grains, then the first pint of the column is not strong enough, and another portion must be percolated with the percolate from the third portion. This portion may be larger or smaller than the others in proportion to the wants of the operator, and

will yield accordingly, the larger portions being more economical.

In the case of dandelion (should not the Pharmacopœia change the English name to taraxacum ?) the Pharmacopœia is estimated to get 86 per cent. or 3222 grains of the extract in its pint. This would make the first two pints of the last dandelion column nearly officinal. But if the standard be reduced to the 80 per cent. uniformity, or 2993 grains instead of 3222 to the pint, the column would yield nearly 2½ pints of that strength.

In the case of senna, the Pharmacopœia, as estimated, may get 78 per cent. or 1972 grains of the extract in its prescribed pint of fluid extract. The last senna column of the table would yield about 2¼ pints of this strength. But if the standard be increased to 80 per cent., or 2032 grains of extract to the pint, the column would yield just 2 pints of this strength.

Of course the weaker percolates of these final columns of this table yield proportionately more when applied to other fresh portions of powder, but in some instances at least, if not in all, repercolation cannot be carried on indefinitely, because of the weak percolate becoming overloaded with extract—the 20 per cent. which is rejected and goes on accumulating—which is assumed here to be medicinally feeble. After a year or two of active practice, it becomes necessary to recover the alcohol from the weaker of the weak percolates, only carrying on the stronger ones. In no case need each separate portion of the residuary weak percolate be kept separate from one making to the next, but the different strengths may be grouped together so as to preserve the whole in three or four bottles for each substance.

From the above considerations it would follow that a fluid extract representing a drug minim for grain, might be defined or described as a solution containing 80 per cent. of the extract of that drug, which is soluble in a given prescribed menstruum. And fluid extract of senna, for example, would be powdered senna repercolated with diluted alcohol until equal volumes of the menstruum and percolate weighed at the same temperature, differ to the extent of 14·5 per cent. = 988 grains to the pint.

The menstrua for fluid extracts need much revision and much research, for upon the menstruum a large part of the therapeutical as well as pharmaceutical success depends. The writer has only very imperfectly studied this branch of the subject, and yet too much time and space would be required to give an abstract of the observations made. He must therefore be content with offering his judgment as based on his experience.

The officinal "alcohol," defined as "spirit of the specific gravity 0·835," seems to be no longer needed in the Pharmacopœia, its place having been well taken by the common so-called "95 per cent. alcohol," or "alcohel fortius" of the Pharmacopœia. This might now be called in the Pharmacopœia, as it is in the market, simply alcohol. Since the last revision of the Pharmacopœia the Government has taken charge of the spirit market, and one result of legislation upon it has been to reduce the strength of the market grades. Ten years ago it was easy to get the so-called "95 per cent. alcohol" and "cologne spirit" from any good maker, containing 92 per cent., or of the officinal specific gravity 0·817. But of late years, in the writer's experience, this is always difficult and generally impossible. In a review of some fifty barrels or more from several good makers, including "Atwood's Alcohol," at various times within the past year, and all bought to special order, and not in the general market, the specific gravity has only once reached ·817, all the others varying between ·818 and ·824 with an average of about ·820. A ten-gallon keg bought in the common market, of a first-rate house, and with the brand of a good maker on it, stamped by the United States Revenue officer as containing "10 wine gallons," "Proof 188," contained 8 gallons and 7 pints, yet gave no evidence of leakage, and had a specific gravity of ·82058. This probably fairly represents the market at the present day, and if so, 91 rather than 92 per cent. should be aimed at by the Pharmacopœia.

Some reform in the mercantile management of alcohol is much needed, and the influence of this Association might be used to bring this about at an earlier day than it would naturally come through popular demand. When the so-called "95 per cent. alcohol" sold for 40 to 45 cents per gallon, the "shortage" of half a gallon or a gallon on each barrel was of far less moment than it is now with a price of $2, or thereabouts; and the difference of temperature between summer and winter,—or between 10° C. = 50° F., and 30° C. = 86° F.—of a fraction over 2 per cent. in the measuring, was also of less moment. Either through erroneous gauging, or through some skill in making barrels, or through both together, it is very rare to find a barrel of alcohol that holds out measure even in summer temperatures, and the rule is that they fall short from half a gallon to one and a half gallons to the barrel, while of late years the writer never knew a barrel to overrun the gauge. And as the United States Inspector's certificate always certifies the gauge, the alcohol-maker throws himself upon this, and there is no redress. Besides this there can be nothing more clumsy, nor more difficult to comprehend in common usage, than the plan of defining the strength by degrees above and below proof, and the quantity by proof gallons. If it was desirable to keep the consumers or users of alcohol so befogged that they could not detect deficiencies in strength or measure, hardly a better plan could be adopted, and the advisers or experts of the General Government, who are responsible for the present method, could not have better subserved the interests of the Whisky Ring, or damaged the interests of the consumer had they been paid for it.

The strength should always be indicated by percentage of absolute alcohol *by weight* and not by volume, and this should be determined by apparent specific gravity.

It should always be bought and sold by weight, the barrels being tared, just as castor oil, linseed oil, cotton-seed oil, etc., are of late years.

Five gallons alcohol, specific gravity ·8202 at 15·6° C. = 60° F., measured at 21° C. = 69·8° F., weighs 34 lbs. avoirdupois, or nearly 6 lbs. 13 oz. to the gallon. This alcohol contains about 91 per cent. by weight of absolute alcohol.

The officinal alcohol fortius, specific gravity ·817, containing about 92 per cent. of alcohol by weight, if measured at 15·6° C. = 60° F., weighs just about the same. So that about 5·4° C. = 9·8° F. of temperature, is equal to 1 per cent. in strength.

If bought and sold by weight, or by weight gallons, which would be the first step, temperature would not have to be taken into consideration.

Alcohol of specific gravity ·81674 at 15·6° C. = 60° F., when weighed at 25° C. = 77° F., has an *apparent* specific gravity of ·808767, and at 30·6° C. = 87° F., ·80400, or about ·00085 for each Centigrade degree of temperature. By apparent specific gravity is meant that although the alcohol is weighed at the higher temperature given, it is compared with the same volume of water at the lower temperature of 15·6° C. = 60° F.

One pint of this alcohol, officinal "alcohol fortius,"

at 10·6° C. = 51° F.	weighs	387·72 gram.	= 5983	grains.
at 30·6° C. = 87° F.		379·87 „	= 5862	„
20° C. = 36° F.		7·85 „	= 121	„

Alcohol of specific gravity ·82154 at 15·6° C. = 60° F. when weighed at 25° C. = 77° F. has an *apparent* specific gravity of ·81342, and at 30·6° C. = 87° F., ·80889, or about ·000843 for each Centigrade degree of temperature. One pint of this alcohol, which is about the common commercial strength,

at 15·6° C. = 60° F.	weighs	388·05 gram.	= 5988	grains.
at 25·6° C. = 78° F.		384·15 „	= 5928	„
10° C. = 18° F.		3·90 „	= 60	„

The next alcoholic menstruum which the writer has found necessary thus far, is a mixture of equal parts, by weight, of stronger alcohol and water. This mixture rejects much more of the troublesome mucilaginous portions of such drugs as dandelion than the diluted alcohol does.

Equal weights of alcohol specific gravity ·81953 at 15·6° C. = 60° F., and water, give a mixture having a specific gravity

at 15·6° C. = 60° F. ·92858.
at 25° = 77° F. ·92003. Difference, ·00089 for each 1° C.

One pint of this mixture

at 10·6° C. = 51° F.	weighs	439·93 grm.	= 6789	grains.
at 30·6° C. = 87° F.	„	433·03 „	= 6682	„
20° C. = 36° F.		6·9 „	= 107	„

(*To be continued.*)

DUST AND SMOKE.

BY PROFESSOR TYNDALL.

(*Concluded from page* 28.)

We have thus been led by our first unpractical experiments into a thicket of practical considerations. In taking the next step, a personal peculiarity had some influence upon me. The only kind of fighting in which I take the least delight is the conflict of man with nature. I like to see a man conquer a peak or quench a conflagration. I remember clearly the interest I took twenty years ago in seeing the firemen of Berlin contending for mastery with a fire which had burst out somewhere near the Brandenburger Thor; and I have often experienced the same interest in the streets of London. Admiring as I do the energy and bravery of our firemen, and having heard that smoke was a greater enemy to them than flame itself, the desire arose of devising a fireman's respirator. But before I describe what has been done in this direction, let me draw your attention to the means hitherto employed to enable a man to live in dense smoke. Thanks to the courtesy of Captain Shaw, I am enabled to show you the action of the "smoke-jacket," known abroad as the "Appareil Paulin," from its supposed inventor. The jacket is of pliable cowhide. It has arms and a hood, with eye-glasses. With straps and buckles the jacket is tied round the wrists and waist, and a strap which passes between the legs prevents it from rising. On the left side of the jacket is fixed a screw, to which the ordinary hose of the fire-engine is attached, and through the hose air instead of water is urged into the space between the fireman's body and the jacket. It becomes partially inflated, but no pressure of any amount is attainable, because the air, though somewhat retarded, escapes with tolerable freedom from the wrists and waist. Hence the fireman, when his hose is long enough, can deliberately walk into the densest smoke or foulest air. But you see the use of the smoke-jacket necessitates the presence of several men; it also implies the presence of an engine. A single man could make no use of it, nor indeed any number of men without a pumping engine. Its uses are thus summed up in a communication addressed to me by Captain Shaw:—

"This smoke-jacket is very useful for extinguishing fires in vaults, stopping conflagrations in the holds of ships, and penetrating wells, quarries, mines, cesspools, etc.—any places, in short, where the air has become unfit for respiration.

"The special advantages of this jacket are its great simplicity, its facility for use, and the rapidity with which it can be carried about and put on; but its drawback is, that it requires the use of an engine or air-pump, and, consequently, is of no service to one man alone. For this latter reason smoke-jackets, although very effective for enabling us to get into convenient places for extinguishing fires, have very rarely proved of any avail for *saving life*."

Now it is that very want that I thought ought to be supplied by a suitable respirator. Our fire-escapes are each in charge of a single man, and I wished to be able to place it in the power of each of those men to penetrate through the densest smoke into the recesses of a house, and there to rescue those who would otherwise be suffocated or burnt. I thought that cotton-wool, which so effectually arrested dust, might also be influential in arresting smoke. It was tried; but, though found soothing in certain gentle kinds of smoke, it was no match for the pungent fumes of a resinous fire, which we employ in our experiments in the laboratory, and which, I am gratified to learn from Captain Shaw, evolves the most abominable smoke with which he is acquainted. I cast about for an improvement, and in conversing on the subject with my friend Dr. Debus, he suggested the use of glycerine to moisten the wool, and render it more adhesive. In fact, this very substance had been employed by the most distinguished advocate of the doctrine of spontaneous generation, M. Pouchet, for the purpose of catching the atmospheric germs. He spread a film of glycerine on a plate of glass, urged air against the film, and examined the dust which stuck to it. The moistening of the cotton-wool with this substance was a decided improvement; still the respirator only enabled us to remain in dense smoke for three or four minutes, after which the irritation became unendurable. Reflection suggested that in combustion so imperfect as the production of dense smoke implies, there must be numerous hydrocarbons produced which, being in a state of vapour, would be very imperfectly arrested by the cotton-wool. These in all probability were the cause of the residual irritation; and if these could be removed, a practically perfect respirator might possibly be obtained.

I state the reasoning exactly as it occurred to my mind. Its result will be anticipated by many present. All bodies possess the power of condensing in a greater or less degree gases and vapours upon their surfaces; and when the condensing body is very porous, or in a fine state of division, the force of condensation may produce very remarkable effects. Thus, a clean piece of platinum-foil placed in a mixture of oxygen and hydrogen so squeezes the gases together as to cause them to combine; and if the experiment be made with care, the heat of combination may raise the platinum to bright redness, so as to cause the remainder of the mixture to explode. The promptness of this action is greatly augmented by reducing the platinum to a state of fine division. A pellet of "spongy platinum," for instance, plunged into a mixture of oxygen and hydrogen, causes the gases to explode instantly. In virtue of its extreme porosity, a similar power is possessed by charcoal. It is not strong enough to cause the oxygen and hydrogen to combine like the spongy platinum, but it so squeezes the more condensable vapours together, and also acts with such condensing power upon the oxygen of the air, as to bring both within the combining distance, thus enabling the oxygen to attack and destroy the vapours in the pores of the charcoal. In this way, effluvia of all kinds may be virtually burnt up, and this is the principle of the excellent charcoal respirators invented by Dr. Stenhouse. Armed with one of these, you may go into the foulest-smelling places without having your nose offended. Some of you will remember Dr. Stenhouse lecturing in this room with a suspicious-looking vessel in front of the table. That vessel contained a decomposing cat. It was covered with a layer of charcoal, and nobody knew until told of it what the vessel contained.

I may be permitted in passing to give my testimony as to the efficacy of these charcoal respirators in providing warm air for the lungs. Not only is the sensible heat of the breath in part absorbed by the charcoal, but the considerable amount of latent heat which accompanies the aqueous vapour from the lungs is rendered free by the condensation of the vapour in the pores of the charcoal. Each particle of charcoal is thus converted into an incipient ember, and warms the air as it passes inwards.

But while powerful to arrest vapours, the charcoal respirator is ineffectual as regards smoke. The particles get freely through the respirator. In a series of them tested downstairs, from half a minute to a minute was the limit of endurance. This might be exceeded by Faraday's method of emptying the lungs completely, and then filling them before going into a smoky atmosphere. In fact, each solid smoke particle is itself a bit of charcoal, and carries on it, and in it, its little load of irritating vapours. It is this, far more than the particles of carbon themselves, that produces the irritation. Hence two causes of offence are to be removed: the carbon particles which convey the irritant by adhesion and condensation, and the free vapour which accompanies the particles. The moistened cotton-wool I knew would arrest the first, fragments of charcoal I hoped would stop the second. In the first fireman's respirator, Mr. Carrick's arrangement of two valves, the one for inhalation, the other exhalation, are preserved. But the portion of it which holds the filtering and absorbent substances is prolonged to a depth of four or five inches. On the partition of wire gauze at the bottom of the space which fronts the mouth, is placed a layer of cotton-wool, moistened with glycerine; then a thin layer of dry wool; then a layer of charcoal fragments; a second thin layer of dry cotton wool, succeeded by a layer of fragments of caustic lime. The succession of the layers may be changed without injury to the action. A wire-gauze cover keeps the substances from falling out of the respirator. In the densest smoke that we have hitherto employed, the layer of lime has not been found necessary; in a flaming building, indeed, the mixture of air with the smoke never permits the carbonic acid to become so dense as to be irrespirable. But in a place where the gas is present in undue quantity, the fragments of lime would materially mitigate its action.

In a small cellar-like chamber downstairs, with a stone flooring and stone walls, the first experiments were made. We placed three furnaces containing resinous pine-wood, lighted the wood, and placing over it a lid which prevented too brisk a circulation of the air, generated dense volumes of smoke. With our eyes protected by suitable glasses, my assistant and I have remained in this room for half an hour and more, when the smoke was so dense and pungent that a single inhalation through the undefended mouth would be perfectly unendurable; and we might have prolonged our stay for hours. Having thus far perfected the instrument, I wrote to Captain Shaw, the chief officer of the Metropolitan Fire Brigade, asking him whether such a respirator would be of use to him. His reply was prompt; it would be most valuable. He had, however, made himself acquainted with every contrivance of the kind in this and other countries, and had found none of them of any practical use. He offered to come and test it here, or to place a room at my disposal in the City. At my request he came here, accompanied by three of his men. Our small room was filled with smoke to their entire satisfaction. The three men went successively into it, and remained there as long as Captain Shaw wished them. On coming out they said that they had not suffered the slightest inconvenience; that they could have remained all day in the smoke. Captain Shaw then tested the instrument with the same result. From that hour the greatest interest has been taken in the perfecting of the instrument by Captain Shaw himself. He has attached to the respirator suitable hoods. The real problem is practically solved, and I can only say that if a tithe of the zeal, intelligence and practical skill were bestowed on the cotton-wool respirator that Captain Shaw has devoted to the fireman's respirator the sufferings of many a precious life might be spared, and its length augmented.*

The lecture was concluded as follows:—"Thus have we been led from the actinic decomposition of vapours

* Mr. Ladd has also proposed a form of mouthpiece which promises well, and Mr. Cottrell has attached to it an ordinary fencing-mask. This will probably be the form of apparatus finally adopted.

through the tails of comets and the blue of the sky to the dust of London, from the germ theory of disease down to this fireman's respirator. Instead of this trivial example I could, if time permitted, point to others of a more considerable kind in illustration of the tendency of pure science to lead to practical applications. Indeed, those very wanderings of the scientific intellect which at first sight appear utterly unpractical, become in the end the wellsprings of practice. Yet I believe there is a philosophy embraced by some of our more ardent thinkers (who, I fear, on many points commit the well-intentioned, but fatal mistake of putting their own hopeful fancies in the place of fact) that would abolish these wanderings of the intellect and fix it from the outset on practical ends alone. I do not think that that philosophy will ever make itself good in the world, or that any freedom-loving student of nature could or would tolerate its chains."

A short time before the lecture I had an opportunity of inspecting the apparatus of Mr. Sinclair, which has been tested and highly spoken of by the superintendent of the Manchester Fire Brigade. The original idea is due to Von Humboldt, who proposed it for the Hartz mines. Galibert constructed the apparatus in an improved form, and it has been still further improved by Mr. Sinclair, who has purchased Galibert's patent. It consists of an air-tight bag, from which issue two tubes that unite on a single one with a respirator mouthpiece. The bag is filled with air, and the wearer inspires through one valve and expires through another. The expired breath is carried to the bottom of the bag, and is stated to remain there in consequence of the chilling experienced in its passage downwards. A bag of not inordinate size is stated to be sufficient to supply a man with air for twenty minutes. Mr. Sinclair's apparatus was exhibited during the lecture.

J. T.

SUPPOSITORIES.

AN INAUGURAL ESSAY, BY F. M. GOODMAN.

(*Continued from page* 27.)

Preparation.—Several years ago it was customary to mould a cone of some vehicle, then bore a hole into its base, and into this opening was inserted the medicinal substance; the opening was then closed by pouring in a little melted vehicle and smoothing off with a spatula. But in boring these holes there is danger of cracking the cone. A much better and far less troublesome method, is to fill the mould with melted vehicle, and when it has begun to *set*, or has formed a thin coating on the inside of the mould, the still liquid portion may be poured out, and a very perfect hollow cone is the result. These cones may be kept on hand, and any substance prescribed can be inserted, and the openings closed as above mentioned.

When the material to be used as a vehicle is melted, it should never be put into the dish in large pieces, for such a prolonged application of heat is necessary to melt them that the substance becomes unnecessarily hot, and consequently requires a considerable time to cool. The best way is to have the material as finely divided as possible. To *cut* it into small pieces, or to *scrape* it, is rather difficult, but the following plan will be found very expeditious, and has the desired effect, viz. Take a plane, such as carpenters use, invert it, letting it be at rest; spread a piece of paper under it, and "cocoa-butter the plane and not plane the cocoa-butter." Having on hand a supply of this shaved material, be it either cocoa-butter and spermaceti, or suet, the necessary quantity is weighed and placed in a dish, and a very slight heat is employed —just enough to render it fluid.

As generally prepared, the medicinal ingredients are intimately mixed throughout the entire mass, which should be perfectly free from lumps, to prevent the accumulation of which is the most difficult part of the operation.

In preparing suppositories it is always best, in the experience of the writer, to use two dishes—one in which to melt the vehicle, and the other to be used for mixing the medicinal ingredients, as extracts, or other substances that may have been ordered. The latter vessel also is to receive the melted vehicle added in small portions from the other dish. If the vehicle is too warm when mixed with the solution of the extract, the extract will separate. This difficulty may be overcome by setting the dish in cold water and stirring constantly till the mixture becomes thick, by which time it is usually smooth. When the remainder of the warm vehicle is added it will raise the temperature of the cooled portion, in doing which its own temperature will be diminished, and the whole will be smooth and uniform. When it has cooled sufficiently, indicated by its consistence, which should be that of honey, it may be poured into the moulds.

In making urethral suppositories, the writer has found the following to be a rather difficult method, though recommended by some. It is certainly less convenient than moulding in a glass tube: Take a sufficient quantity of the shaved material, place in a dish and heat enough to render it a *little soft* (without melting it)—about the consistence of paste. This can also be done in a warm mortar, which, being very thick, will retain the heat for a considerable length of time; enough of the substance may be removed to make one or two suppositories, and the remainder will retain its soft condition while left in the warm mortar. While the substance is in this semi-solid condition, remove it from the dish or mortar to a board about twelve inches wide, divided into two-inch spaces. The board is constructed on the principle of a pill-machine, having strips on either side, so arranged that they may be replaced by strips of other sizes, according to the diameter desired for the finished suppository, which varies from one to three-sixteenths of an inch. There is also provided a flat piece of wood for a roller. The material is placed upon the board, and rolled out as in rolling pills, into pieces which may be twelve inches long, if the operation be successfully conducted. The rolled mass is then divided into equal parts according to the two-inch marks upon the board.

The difficulty in this process is that the substance is not very tenacious, and upon cooling cracks and crumbles beneath the roller, though one or two may be rolled at a time very readily.

When the urethral suppository is moulded in the funnel-tube, the method adopted to remove the moulded mass is to get the tube *very* cold, so that a little pressure with the piston will expel it, or, to get it thoroughly chilled, then to dip it into water warmed to about 85° or 90° F., and removing it from the water, to apply pressure by the piston; when two inches are expelled, cut it off, and expel two inches more, etc. When cut off, the pieces may be laid gently on a piece of paper, or allowed to drop into cold water.

In order to fill this tube, the lower end must be closed, which may be done by dipping it into the melted vehicle, placing the finger over the upper orifice, and then holding the lower end in cold water. The substance within the end will congeal and prevent the egress of the liquid portion subsequently added.

In using the metallic moulds, it is a source of great annoyance to have the suppository stick fast to the mould, which is invariably caused by not having the mould cold when filled. This is an extremely essential point. The tray should be filled with ice and water, and allowed to stand a few minutes before using, in order that the mould may become thoroughly chilled.

In an article written by Mr. J. B. Moore, which appeared in the *American Journal of Pharmacy*, vol. 40, page 226, he considers it in accordance with a good product to have the moulds dusted with lycopodium, arrowroot, or other similar substance, as *well* as being chilled, and this *may* be essential if the moulds are *never cleaned*, but is certainly not, as he has probably observed, if they are properly polished. A mould, after having been used five or six times, should be well cleaned with powdered pumice, then polished with whiting, and this *must* be done if we expect a good product.

In making extract of opium suppositories, some powder the extract, in order to do which it has to be perfectly dry, and in drying it loses from 5 to 15 per cent. of moisture, which necessarily increases its strength. The writer, however, prefers reducing this extract, as well as most others, to a thin consistence with water, which in the amount necessary is unobjectionable. Sometimes glycerine is better.

Elm is frequently prescribed in the form of a suppository for its emollient effect, and may be incorporated in the following manner: Cut the elm into small thin strips, macerate for half an hour in hot water, strain through muslin with strong expression; repeat the maceration and straining again; mix the strained liquids and evaporate. If any salts are prescribed in connection with the elm, they should be dissolved separately and mixed with the mucilage, and the whole should be evaporated to a very thick consistence; to this paste, while still hot, the melted vehicle should be added, in small quantities at a time, with vigorous stirring. When it begins to thicken, fill the moulds, and when cold, with a spatula, scrape the surface quite level.

If the operations have been properly conducted, the suppositories will drop out upon inverting the mould.

From the foregoing remarks we extract the following three paragraphs as giving the essential requirements for the production of perfect suppositories:—

First. Have the moulds clean.

Second. Have them very cold when filled.

Third. Have the substance about the consistence of treacle when poured into the moulds.

Dispensing.—In dispensing suppositories care should be taken that they are placed in a box of the proper size, and are well packed to prevent their being broken while in the hands of the messenger. In very warm weather some pharmacists direct the messenger to carry the package by a loop in the string, which they form for that purpose in tying it up. This is to prevent their becoming soft, which might happen if put into the pocket or grasped with the hand; but this precaution is unnecessary in moist weather; indeed, it can scarcely be called a *precaution*, for, being carried in that manner it is apt to be exposed to the direct rays of the sun during transportation, which would be more apt to fuse them than the heat from the body.

It is customary to place cotton above and below the suppositories in dispensing, and for this purpose the common white cotton is frequently employed, but the bright pink, or jeweller's cotton, appears much better. It should be laid on the counter and pressed with the hand, and then cut of the proper size to fit the box, which should be of the following dimensions:—for one dozen vaginal, three and one-fourth inches long, two and one-fourth inches wide, one and three-fourth inches deep. For one dozen rectal, two inches long, one and a half inches wide, one and three-eighth inches deep.

The box should be constructed with regard to its use, and be made of some material that will not show the grease spots. A box covered with paper made in imitation of morocco, of a dark brown or black colour, is perhaps best adapted to this purpose, for it does not show the grease, and on this account would be preferred by all who wish the reputation of neat and tasty dispensers.—*The Chicago Pharmacist.*

THE PHARMACY BILL.

MEETING AT HULL.

At a Meeting of Chemists and Druggists, held on Tuesday evening at the Cross Keys Hotel, Market Place, Hull, which was well attended, Mr. Baynes in the chair, the following resolutions were unanimously adopted:—

"1st. That this Meeting having carefully considered the proposed Government amendments to the new Pharmacy Bill, acknowledges the desire of the Right Honourable W. E. Forster to meet the wishes of the trade, but is of opinion that the compulsory and penal clauses of the amended Bill are highly objectionable, and would fail to accomplish the objects sought, and strongly urges the withdrawal of the Bill, or reference to a select Committee, it being impossible to deal with the question of poisons during the present session of Parliament, and without full information on the subject."

"2nd. That in the interests of the public, and on principle, this meeting strongly objects to any compulsory regulations or penal restrictions, which do not apply to all dispensers of poisons alike, whether keeping open shops or not."

"3rd. That the best and most effective protection against accidental poisoning is the competency of the dispenser, and this being provided for by the Act of 1868, and registered chemists being already under stringent regulations in the sale of poisons and heavy responsibilities in the event of culpable negligence, and abundant evidence having been found during the recent agitation that great care is exercised by them in the dispensing and storing of poisons in the manner best adapted to their respective businesses, so as to ensure freedom from accidents, this meeting is of opinion no necessity exists, nor can any case be established for special legislation in the case of registered chemists."

"4th. That the preamble of the Pharmacy Act, 1868, declaring it is expedient for the safety of the public 'that chemists and druggists should possess a competent practical knowledge of their business,' will be best complied with and the object attained, by the Pharmaceutical Society devoting itself energetically to the advancement of pharmaceutical education, especially in the provinces, and that any action taken by the Society having reference to the internal management of pharmacies, should be in the form of suggestions or recommendations only, it being, in the opinion of this meeting, impossible to frame regulations which could safely or judiciously be made compulsory on all chemists throughout the kingdom."

"5th. That the Secretary be instructed to forward a copy of the foregoing resolutions to the Members of Parliament for the borough and East Riding, asking them still to oppose the Bill, and that they be forwarded to the Pharmaceutical Journal."

MEETING AT NEWCASTLE-UPON-TYNE.

A Meeting of the Pharmaceutical Chemists and Chemists and Druggists of Newcastle-upon-Tyne and Gateshead, was held in the College of Medicine, Newcastle, July 12, 1871, to consider the alterations proposed to be made in the "Pharmacy Act Amendment Bill;" J. W. Swan, Esq., in the chair.

The Bill as first printed, together with the proposed amendments having been read and considered, it was moved by Mr. Swan, seconded by Mr. Hunter, and resolved, "That this meeting sees in the new Pharmacy Bill an uncalled-for, premature and dangerous unsettling of the Act of 1868, under which poison regulations are now in force, and which duly provides for the enactment of additional regulations, presumably on the necessity for such arising; that in the opinion of this meeting the question of the enactment of additional compulsory regulations is one of so delicate and dangerous a nature that its settlement demands the utmost care and deliberation at the hands of those who are practically acquainted with the subject; and that whereas there is an entire absence of public urgency in the case, and even considerable risk of increased danger resulting from hasty and unpractical legislation, therefore it is desirable to allow the Act of 1868 to continue without the interference of any new legislation."

It was moved by Mr. Brockett, seconded by Mr. Owen, and resolved, "That inasmuch as the principal portion of the dispensing of medicines in Great Britain is performed by medical practitioners who will not be affected by the Bill even in its amended form, the proposed legislation would establish the striking anomaly, that poisons under the Act would or would not be subject to regulations according to the *place in which they were dispensed*, without any relation to their dangerous properties; this meeting, therefore, regards the measure as unwise, impolitic and unjust."

Moved by Mr. Coates, seconded by Mr. Hall, and resolved, "That this meeting is of opinion that the regulations for the storing of poisons, contained in the schedule of the amended Bill, are unsuited to the case, and unlikely to produce any good results; and further, that the schedule of poisons contained in the Act of 1868, intended to regulate the *sale* of poisons, is totally unfitted as a basis for regulations in respect to *storage* and *dispensing*."

Moved by Mr. Eno, seconded by Mr. Jobson, and resolved, "That in the opinion of this meeting, the only safeguard at present needed in addition to the regulations relating to the sale of poisons imposed by the Act of 1868, is improved education, and that is already provided for by the compulsory powers of the Pharmaceutical Society in respect to examinations."

It was announced by Mr. Owen that, in accordance with the resolution of a former meeting, upwards of £40 had been subscribed by chemists in Newcastle and some of the surrounding towns towards meeting past and prospective expenses in opposition to obnoxious legislation, and that after meeting expenses up to the present time, he had been enabled to invest in a building society the sum of £25, that the Secretary might feel that there was a little fund at his back whenever he might see necessary to take prompt measures for the protection of the trade.

MEETING AT MANCHESTER.

Copy of resolutions unanimously passed at a Meeting of Pharmaceutical Chemists and Chemists and Druggists, held at the Memorial Hall, Albert Square, Manchester, July 12th, 1871:—

Moved by Mr. Gill, seconded by Mr. Kerfoot, "That this meeting of the Pharmaceutical Chemists and Chemists and Druggists of Manchester and vicinity, is of opinion that the amendments to the Pharmacy Bill do not remove or mitigate the objections to the proposed legislation, and desires to express its determined and continued opposition to the Bill.

"1st. As it deprives the members of the Society of a constitutional right conferred by clause 1 of Pharmacy Act, 1868.

"2nd. It introduces into an Act of Parliament legislation for minute details of internal business arrangements, which would expose chemists to great inconvenience, from the large number of articles to which regulations would apply and the varying interpretation put on the requirement.

"3rd. That as the Act of 1868 makes full provision for sale of poisons, and prescribes educational qualifications for all dealers, the public is amply protected, and further legislation for storing is uncalled for and unnecessary, and would, indeed, be prejudicial as tending to weaken the sense of personal responsibility.

"4th. That the imposition of heavy penalties for undefined offences will be most unjust, vexatious to the trade and against public interest.

"5th. That the strong and almost unanimous expression of opinion from the trade is entitled to respect, and as the amendments proposed do not touch the objectionable principle of the Bill, as interfering unduly and unjustly with the freedom of an educated and responsible body of men, it is hoped that Members of Parliament will not relax their efforts to procure the withdrawal of the measure."

Moved by Mr. R. Hampson, seconded by Mr. W. Wilkinson, "That a copy of this resolution be forwarded to all Members of Parliament."

MEETING OF CHEMISTS AND DRUGGISTS AT LEEDS.

A Meeting of Registered Chemists was held on Wednesday, July 12th, at the Philosophical Hall, Leeds; Mr. W. Smeeton, President of the Leeds Chemists' Association, in the chair.

The following resolutions were carried unanimously:—

Moved by Mr. G. Ward, F.C.S., seconded by Mr. E. Yewdall, "That this meeting has carefully considered the amendments to the Pharmacy Bill offered by the Right Hon. W. E. Forster. It thankfully recognizes them as improvements, and their introduction as supplying an ample justification of past opposition to the Bill; viewing the amended Bill upon its merits, this meeting feels compelled to record its opinion, that by its partial application to dispensers of medicine, it would cause increased danger to the public, would be harsh and unjust towards those to whom it applies, and that its inconsistencies would bring into disrepute the principle of the systematic storing of drugs."

Moved by Mr. S. Taylor, seconded by Mr. J. Day, "That copies of the foregoing resolution be sent to the members for the borough and the division of the West Riding, and that they are requested to give Mr. Torrens the support of their votes in opposing the Bill, or at least promote its being referred to a Select Committee for further inquiry."

The thanks of the meeting were voted to the Chairman.

MEETING AT NOTTINGHAM.

At a large and important Meeting of the Chemists of Nottingham and district, held in the rooms of the Nottingham and Nottinghamshire Chemists' Association, the following resolutions were unanimously adopted:—

Moved by Mr. Waterall, seconded by Mr. Parker,—

"That the objections of this meeting to the Pharmacy Bill now before Parliament are,—

"1st. That the Act of 1868 did not pledge the Pharmaceutical Society to institute regulations of a compulsory character for the dispensing, keeping and selling of poisons.

"2nd. That such regulations are unnecessary, an unwarrantable interference with the freedom, and an insult to the intelligence of the chemists as a body.

"3rd. That regulations only applying to those keeping open shop, and not to all dispensers of medicine, are partial and unjust.

"This meeting, having discussed and considered the proposed amendments to the Pharmacy Bill introduced by the Right Hon. W. E. Forster, and, whilst acknowledging the concessions, regrets its inability to accept them, as removing the objections to the Bill."

Proposed by Mr. White, seconded by Mr. Jackson,—

"That the resolutions passed at this meeting be forwarded to the Members of Parliament for the town and county of Nottingham, with the earnest request that they will continue to support the prayer of the petition already presented to the House against the Bill."

The Pharmaceutical Journal.

SATURDAY, JULY 15, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACY AND THERAPEUTICS.

THE proposal introduced by Professor PARKES, seconded by Professor CHRISTISON, and carried by a considerable majority of the Medical Council, to the effect that pharmacy should form an early subject of the student's curriculum, and that therapeutics should be taught as a separate branch at a later period, was justly described by Dr. ANDREW WOOD as one of the most important measures which that body had ever discussed and passed. In most schools, south of the Tweed particularly, the two subjects were taught together, and at a stage of the student's career when he could derive least profit from the study. In others, pharmacy was taught to the almost entire exclusion of therapeutics, or *vice versâ*, according to the taste or convenience of the lecturer. This unsatisfactory state of matters comes to an end as soon as the licensing and teaching bodies adopt (as they can hardly refuse to do) the proposal of their representatives in the Council.

Scarcely less important than this innovation on previous academic arrangements, was the suggestion also introduced by Dr. PARKES, that pharmacy should be taught in the tutorial or practical method, and not, as is so often done, from the professorial chair. This latter method was justly denounced by Sir DOMINIC CORRIGAN as preposterous,—the students acquiring painfully in the form of lectures what could far more conveniently be learned from a book, or, best of all, from tutorial instruction and demonstration in a well-appointed laboratory, or even shop. The time, indeed, is not far distant when the two subjects—pharmacy and therapeutics—will not only be taught separately in the medical student's course, but will finally be apportioned to distinct callings; the former to the duly qualified pharmaceutical chemist, the latter to the duly qualified medical practitioner. Division of labour is becoming more and more the rule in the professions,—in none more than in the healing art. The time allotted to the medical student for perfecting himself in the sciences preliminary to his purely professional studies is all too brief for the purpose; and his educators are more and more convinced that certain subjects should either be entirely dropped from his curriculum, or relegated to an inferior place in it. They are the less reluctant to advocate such a policy when they find that those subjects belong more properly to other callings, with whose members they may safely be left in trust. Such a subject is pharmacy. The public will have as much confidence in the medicines prepared by the duly qualified pharmaceutist as in the prescriptions enjoined by the duly qualified practitioner,—certainly more confidence in each exercising his proper functions apart than attempting to fulfil the functions of both. The guarantee that drugs are prepared *secundum artem* is as valid as the guarantee that they are prescribed *secundum artem*; and it seems useless to insist on medical students qualifying themselves for the former when they have but too little time to qualify themselves for the latter.

POISON REGULATIONS.

IT will have been evident to our readers that the amendments introduced into the Pharmacy Bill by Mr. FORSTER indicate on his part a much greater disposition to consider the objections raised to the Bill in its original form than was apparent when the deputation waited on him on the 24th ult. Without attempting to discuss the question whether the amendments sufficiently meet the objections that have been urged, we think it right to state that some opponents of the Bill are now disposed to take a more favourable view of it.

The action hitherto taken in reference to the Bill certainly indicated that it was opposed by a majority of members of the Society and of the trade, and the letters published this week will show that there is still a strong opposition to it. However, those who look with favour on the Bill are exerting themselves, and it is but just to them as well as to the opposing party, that we should make this known.

We have been requested by Mr. SANDFORD to publish a letter which he has addressed to the Local Secretaries of the Society, calling upon them and the members generally to exercise their independent judgment on the amended Bill, but urging various considerations which, in his opinion, should induce them to waive further opposition.

We have also been requested by the Secretaries of the two Chemists' Defence Associations to publish a circular which they have addressed to the trade, stating reasons for recommending uncompromising opposition to the amended Bill.

Both these documents appear to be of such importance as to claim a prominent place in the Journal, and therefore we print them together here in the order they reached us, and we commend them equally to the careful consideration of our readers.

"47, PICCADILLY, LONDON,
"*July* 10*th*, 1871.

"Sir,—My long and intimate association with the Pharmaceutical Society, my seven years' experience of the duties of the Presidency, and my personal connection with the Pharmacy Act of 1868, embolden me to believe that I shall, at least, be favoured with a fair hearing if I venture on the somewhat unusual course of addressing my fellow-members at this very important epoch in the existence of the Society. I think I am justified in calling the present conjuncture of affairs an epoch, because the Act of '68, which gave us great privileges, affixed as a condition thereto the performance of a certain duty, and this being the period when, by some means or other, regulations are to be commenced, I think it may fairly be called an epoch. This brings me to the question, all important at this moment, how shall those regulations be made? Do not imagine, if you please, that the notion of a duty undertaken is my own merely; all Members of Parliament with whom I have talked on the subject, whether they be favourable or adverse to the new Pharmacy Bill, agree in such an interpretation of the first section of the Act of '68.

"The facts of the case stand thus:—The Pharmaceutical Society declined at its last Annual Meeting to prescribe *regulations*, but set its seal of approval on certain methods of storing and dispensing poisons which had been most carefully set down by men knowing on the one hand the dangers, on the other the difficulties, in the way of dispensers. The Privy Council, who are in fact concerned in carrying out the Act of '68, said, naturally enough, you have not done your duty, and we must either urge you to do it, or do it ourselves independently of you. Hence the origin of the Pharmacy Bill which passed the House of Lords a few weeks ago, and is now in progress in the Commons. I would not have you under any misapprehension respecting the delay which has arisen. When the Bill came for second reading last Thursday, it was not postponed for any reason which concerns the Bill itself, as you may see by the discussion which has been published in the PHARMACEUTICAL JOURNAL, but merely because many members wished to protest against a growing infringement on the forms of the House, *i.e.*, reading Bills which are to be extensively altered, without giving the House a previous opportunity of seeing what those Amendments are.

"The Bill originally proposed is short and simple. It gives to the Council of our Society the power to submit regulations, from time to time, to the Privy Council for approval, and, if need be, to amend or revoke such regulations. It then states that if no regulations are in force, the Privy Council may call on us to frame some; and if we fail to do that and obtain the approval of the Privy Council thereto, that body may act without reference to us.

"When this Bill was first brought to our notice, the Council discussed its merits and demerits, resolved to watch its progress and endeavour to improve it.

"I was deputed, with the President, to see the officials of the Privy Council; and on doing so, we were met freely and fairly by concessions at once. First it was proposed to take away all initiative power from the Privy Council, by embodying *our own regulations* in a schedule to the Bill, and giving us authority to amend and revoke them from time to time, with approval of the Privy Council. Next it was agreed to add a clause which would compel *all* persons keeping open shop to observe the same regulations. Thus the two grievances were removed, and chemists would not be branded with what had been called the indignity of conforming to rules from which others were exempted. I thought we had thus succeeded admirably; but at a future meeting the Council, by a majority of *one*, decided still to oppose rather than amend, *although generally admitting that the objections to the Bill had been removed;* and you have had circulars, asking you, as plainly as possible, to confirm them in this opposition. It is at this conjuncture that I ask you to exercise your *free and independent* judgment in the matter,—not simply to continue your agitation if you disapprove, but if you approve, and think with me, that the Bill in its amended form (the Poison bottle, let me remind you, has been struck out of the dispensing clause) will be the best settlement we can hope to get of the question, and that an early settlement will be conducive to the good of our Society, to signify to those who represent you in Parliament that these fair Amendments being made, you no longer desire to obstruct its progress. In order that you may see exactly the scope of the Amendments, I enclose herewith a copy of the original Bill, side by side with a draft of that which will be submitted to the House on Monday next by Mr. Forster. We know the nature and extent of the regulations; we know that they are already adopted in very many establishments both in London and the country; that they are so elastic that almost any pet method of storing poisons which is not named in them would not be excluded by them; and further, that at a very full meeting of our Society a majority of nineteen only decided against making them at once compulsory. Beyond all this, we know that if, owing to the late period of the session, the Bill be shelved now, it will surely be reproduced at the very commencement of next session, when time will be in favour of the supporters rather than the opponents of the Bill, and perhaps 'Inspectors,' the necessity for whose appointment was so kindly suggested to Mr. Forster by the deputation a fortnight ago, may be provided for us.

"I could find many members of our Council—perhaps even a majority—to sign this letter with me, but as I am already a marked man for venturing to uphold what I believe to be the best interest both of the Society and the trade, in opposition to the last voting of my colleagues, I prefer standing alone in this communication, and I am sure you will believe me always

"Very faithfully yours,

"GEORGE W. SANDFORD."

Original Clause.	*Amended Clause.*
And the Council of the said Society may from time to time submit to the Privy Council regulations as to the keeping, dispensing and selling of poisons within the meaning of the principal Act, and as to revoking or amending any such regulations previously made, and the Privy Council may, if they think fit, by order approve of such regulations. If at any time it appear to the Privy Council that there are no regulations for the time being in force under the principal Act as to the keeping, dispensing and selling of poisons within the meaning of the principal Act, the Privy Council may serve a notice on the Council of the Pharmaceutical Society requiring them to frame and submit for the approval of the Privy Council regulations as to the matters aforesaid; and if the Council of the Pharmaceutical Society, within the time limited by such notice, not being less than two months from the date of the service of the notice, make default in framing such regulations, or obtaining the approval of the Privy Council thereto, the Privy Coun-	After the first day of October, 1871, the regulations as to the keeping, dispensing and selling of poisons within the meaning of the principal Act, which are set out in the schedule to this Act, shall be observed by all persons who keep open shop for the retailing, dispensing or compounding of poisons, and shall have the same effect as regulations prescribed in manner specified in the principal Act, and the provisions of the principal Act relating to such regulations shall be construed accordingly. Every person who keeps open shop for the retailing, dispensing or compounding of poisons, and fails to conform with any of the said regulations shall, notwithstanding anything contained in section sixteen of the principal Act, or in section one of the Pharmacy Act, 1869, be liable to a penalty not exceeding in the case of the first offence five pounds, and in the case of a second or any subsequent offence ten pounds, which penalties may be recovered on summary conviction as penalties under the principal Act may be recovered.

cil may themselves frame regulations as to the matters aforesaid.	The Council of the Pharmaceutical Society may from time to time, by resolution approved by the Privy Council, revoke, alter and add to the regulations contained in the schedule to this Act, or made in pursuance of this section, and make new regulations in their place; and such resolution so approved shall, on coming into operation, have effect as if it were contained in the schedule to this Act.
All regulations approved or framed by the Privy Council in pursuance of this section shall have the same effect as regulations prescribed in manner specified in the principal Act.	Every resolution so approved shall be published in such manner as the Privy Council may direct, and shall come into operation at the date of such publication, or such later date as may be specified in the resolution.

"Dear Sir,—The defeat of Mr. Forster's effort to read the Amended Pharmacy Act the second time last Thursday night, speaks volumes in favour of the action which has been taken in opposing this obnoxious Bill. It has been observed by one fully conversant with the general routine of business in the House of Commons, that to find so many independent members remain till so late an hour, except on special occasions, is a most uncommon occurrence, and powerfully evinces the interest taken in the present subject. The thanks of the whole trade are due to these gentlemen for thus practically demonstrating to their constituencies that the numerous expressions of dissent to the Bill which had been received were not disregarded, but that their interests were considered and watched by their representatives. Would that we could extend the compliment to all our representatives at Bloomsbury Square! We should not then find ourselves in the anomalous position of having to protect ourselves by combined action against those who ought to be our protectors.

"Having touched upon this subject, we cannot refrain from further expressing the feeling of regret which pervades the trade at seeing persons, whose election our two Associations supported, on the distinct avowal of sympathy with our views, now systematically voting in opposition to those opinions.

"In consequence of the alterations proposed by Mr. Forster, and confidentially communicated to the Pharmaceutical Council for consideration at the Meeting held Wednesday the 5th, a lengthy and earnest discussion took place, resulting in the adoption of the following resolution:—'That this Council has carefully considered the amendments to the Pharmacy Bill, introduced by the Right Hon. W. E. Forster, and regrets that it is unable to accept them as removing its strong objections to the Bill.' The members voting as a majority in favour of this resolution were,—Messrs. Atherton, of Nottingham; Bottle, of Dover; Frazer, of Glasgow; Reynolds, of Leeds; Sutton, of Norwich; Woolley, of Manchester; Betty and Greenish, of London,—showing most distinctly that—if these gentlemen reflect the opinions of their constituencies,—all the large towns and centres of population continue firm in their opposition to the Amended Bill.

"Let us now for a moment consider the position in which these amendments place us.

"In the first place, all open shops are now included. Does this satisfy us? Are we to be silenced by the fact that others will be drawn into the net in which we are threatened to be taken? Assuredly not! In all our personal interviews with members of Parliament we have been most careful, when exhibiting the anomaly of making laws applying to chemists, whilst others keeping open shops identical with our own were left unfettered, to assert our distinct objection to the principle of Government interference in such matters of practical detail, and also the absence of any desire on our part to inflict on others burdens and penalties to which we so strongly object for ourselves. If Mr. Forster's desire, however, is really the protection of the public, in order to be fully consistent therein he must of necessity include not only surgeons with open shops, but hospitals, dispensaries, infirmaries, wholesale dealers, oil and colourmen, drysalters, and every place where poisons are prepared, kept, or supplied in any way for public use, otherwise his Bill will be but partial in its operation, and unjust in its principle.

"A second alteration is, the removal of the power of initiating regulations from the hands of the Privy Council into the hands of the Pharmaceutical Council, the effect of which would be to deprive the Society, in its corporate capacity, of the power it now possesses of accepting or rejecting such additional regulations, and transferring the entire authority and power into the hands of the Pharmaceutical Council. To this we also distinctly object. Our voices have hitherto been raised against the assumption of that power by the Privy Council, on the ground that members of that body are of necessity ignorant of the essential practical details; we now, with equal distinctness, protest against the members of the Pharmaceutical Society being excluded from the power of expressing an opinion upon questions which vary so considerably in different localities, remembering that the representative character of that Council (as regards locality) may at any time, by circumstances over which we can have no control, be entirely destroyed, as illustrated only a few months since, when the seven members of Council elected by 'drawing of lots' were every one provincial men, leaving London entirely unrepresented.

"The third alteration is also one of great importance, appealing to every one of us in accents unmistakable, viz. the increase of penalty for omitting to carry out the prescribed regulations from five to ten pounds, for the second and subsequent offences against the law. Added to which, according to the 26th clause of the Act, 1868, the Privy Council may direct the name of any person convicted of any offence against this Act to be erased from the register.

"This we consider a most arbitrary exercise of power which in practice would be highly prejudicial to our interests, and add very materially and unnecessarily to our anxiety in conducting business.

"For the above reasons we feel satisfied you will feel it your duty to use every possible effort to prevent the passing of the Bill next Monday, the 17th inst.; to this end we would remind you that nothing carries more weight to the minds of your representatives in Parliament than communications from their own constituents. We would venture therefore to press very earnestly upon you to write, without a day's delay, to your members, showing them that the alterations, instead of removing objections, simply extend the ground of our disapproval, and urging upon them to give the Bill their unqualified opposition.

"We would further suggest that any surgeons keeping open shops in your neighbourhood should at once be made aware of the alterations in the Bill, by which they will be brought under the control of the Council of the Pharmaceutical Society.

"We are, Sir, your obedient servants,

"ROBT. HAMPSON, *Hon. Sec. to the*
"*Chemists' Defence Association, Manchester.*

"EDWIN B. VIZER, *Hon. Sec. to the*
"*Metropolitan Chemists' Defence Association.*"

THE REGISTER.

We have already had occasion to call attention to grave inaccuracies in the Register, and to defects in the provisions of the Pharmacy Act, 1868, for the keeping of a Register. These defects have lately been rendered apparent in sending out the circular of recommendations as to the keeping, dispensing and selling of poisons; for out of 12,894 persons whose names are on the Register, circulars could be sent to only 12,550, owing to defective addresses; and out of the circulars sent, 1065 were returned through the Dead Letter Office. According to this, there appear to be 1409 errors in the Register.

In order to remedy this state of things, advantage has been taken of the Pharmacy Act Amendment Bill now before Parliament, and, with the consent of Mr. Forster, a section has been introduced into it, amending the provisions of the Act of 1868.*

We call attention to this matter because it seems to be one of the points to be weighed in considering the Bill as now amended, and because it is of importance to the whole trade that a correct Register should be kept.

The Guernsey *Star* reports that a silver medal has been awarded to Mr. Adolphus Arnold, of Guernsey, for his "iodine and chemical products from sea-weed" and "sea-salt" exhibited in the Channel Islands Exhibition.

Transactions of the Pharmaceutical Society.

July 5, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.
MR. EDWARDS, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Carr, Frazer, Greenish, Groves, Hills, Reynolds, Sandford, Savage, Shaw, Smith, Sutton, Williams, and Woolley.

The minutes of the previous meetings were read and confirmed.

Pharmacy Bill.

The President called the attention of the Council to the following letter, received from the Medical Officer of the Privy Council:—

"*Medical Department of the Privy Council*,
"*July 4th*, 1871.

"Sir,—I am directed by Mr. Forster to inform you that he has drafted certain clauses, which he is ready to propose as Amendments to the Pharmacy Bill now before Parliament, and which he hopes would remove the objections which your Society has expressed to the Bill in its present form.

"And I am to say that Mr. Forster has given instructions that a copy of his proposed amendments should be sent to you by the printer as early as can be to-morrow morning, with a view to your bringing them at once under the consideration of the Council of the Society.

"I am, Sir,
"Your obedient servant,
"(Signed) John Simon.

"*The Secretary to the*
"*Pharmaceutical Society.*"

The Secretary then read the proposed amendments, and laid copies on the table.

* See p. 35.

The President observed that as the subject now before the Council was important, and demanded immediate consideration, he would at once submit a motion thereon.

It was accordingly moved by the President, seconded by the Vice-President,—

That this Council considers the amendments which the Right. Hon. W. E. Forster proposes to make in the Pharmacy Bill satisfactory, and hereby withdraws its opposition to that Bill.

Amendment—

Moved by Mr. Betty, seconded by Mr. Woolley,—

That this Council has carefully considered the amendments to the Pharmacy Bill introduced by the Right Hon. W. E. Forster, and regrets that it is unable to accept them as removing its strong objections to the Bill.

For the Amendment (9)—

Messrs. Atherton, Betty, Bottle, Frazer, Greenish, Reynolds, Shaw, Sutton and Woolley.

Against (8)—

Messrs. Carr, Edwards, Groves, Haselden, Hills, Sandford, Smith and Williams.

Mr. Savage was present at the division, but did not vote.

The amendment was then put as a substantive motion and carried.

Moved by Mr. Betty, seconded by Mr. Woolley—

That the Report of the Council's vote on the Pharmacy Bill be furnished to Mr. M'Cullagh Torrens.

Moved by Mr. Edwards, seconded by Mr. Williams—

That the *number* and *names* of those who voted be added to the Report sent to Mr. Torrens.

For (9)—

Messrs. Carr, Edwards, Frazer, Groves, Haselden, Hills, Sandford, Smith and Williams.

Against (7)—

Messrs. Atherton, Betty, Bottle, Greenish, Reynolds, Shaw and Woolley.

The Amendment being carried, the motion was passed with the additional words.

Moved by Mr. Hills, seconded by Mr. Frazer, and

Resolved—That the Right Hon. W. E. Forster be applied to for permission to publish the draft Amendments, which have been submitted to this Council this morning, in the next issue of the Journal.

Moved by Mr. Bottle, seconded by Mr. Reynolds, and

Resolved—That the Secretary do report to the Right Hon. W. E. Forster the decision of this Council in reference to his proposed Amendments to the Pharmacy Bill.

Admission of Reporters.

Mr. Betty, who had given notice of a motion on this subject, withdrew it in favour of Mr. Reynolds.

Moved by Mr. Reynolds, seconded by Mr. Betty—

That this Council is willing that reporters for the press should attend its sittings, a separate application being made on behalf of each Journal desirous of such attendance, and the permission that may be granted being subject to the continued willingness of the Council.

Amendment, moved by Mr. Carr, seconded by Mr. Sandford—

That the Society's own reporter be engaged to attend the monthly and special meetings of the Council, for the purpose of taking a full report of the proceedings, that the Publication Committee be authorized to publish in the Journal and Transactions of the Society the whole, or such portion of the Report as they may deem necessary.

For the Amendment (10)—
Messrs. Bottle, Carr, Edwards, Frazer, Groves, Haselden, Hills, Sandford, Sutton and Williams.

Against (8)—
Messrs. Atherton, Betty, Greenish, Reynolds, Savage, Shaw, Smith and Woolley.

The Amendment was then put as a substantive motion, and carried.

The Report of the Finance Committee was presented, showing on the General Fund account a balance in the Treasurer's hands of £2509. 18*s.* 0*d.*, and submitting for payment accounts, salaries, etc., amounting to £1470. 9*s.* 9*d.*; and showing on the Benevolent Fund account a balance of £578. 14*s.* 7*d.*

Resolved—That the Report be received and adopted, and payments made.

Resolved—That the Treasurer be requested to pay the several annuitants their quarter's annuities in advance to Michaelmas next.

Resolved—That the Report of the Library, Museum and Laboratory Committee be received and adopted.

The Committee having recommended that certain gentlemen should be deputed to make arrangements for the Evening Meetings of the Pharmaceutical Society, it was

Resolved—That the following be requested to undertake that duty:—The President, Vice-President, Mr. Daniel Hanbury, F.R.S., Professors Redwood, Bentley and Attfield, and Dr. Paul.

Resolved—That the Reports and Recommendations of the Parliamentary Committees of the 14th, 19th and 24th June, and 4th July be received and adopted.

Resolved—That the Report of the Provincial Education Committee be received and adopted, and that the Treasurer be requested to pay the following sums recommended by the Committee:—

Ten pounds to the Society of Chemists and Druggists of Aberdeen.

Ten pounds to the Nottingham and Notts Chemists' Association.

Ten pounds to the Midland Chemists' Institute.

Moved by Mr. Carr, seconded by Mr. Groves,

Resolved—That the Report of the Special Committee "to direct the operations of the Society in communicating with the local secretaries and members upon the subject of opposing the Bill" be received and adopted.

Professor Redwood was reappointed Professor of Chemistry and Pharmacy for the ensuing year.

Professor Bentley was reappointed Professor of Botany and Materia Medica for the ensuing year.

Professor Attfield was reappointed Professor of Practical Chemistry and Director of the Laboratory for the ensuing year.

William Augustus Tilden, D.Sc., was reappointed Demonstrator for the ensuing year.

Mr. John Moss was reappointed Assistant Demonstrator for the ensuing year.

Dr. Paul was reappointed Editor of the Society's Journal for the ensuing year.

Mr. Francis Passmore was reappointed Sub-Editor of the Society's Journal for the ensuing year.

A letter from the Medical Department of the Privy Council office was read, approving the appointment of Examiners for England and Wales and Scotland.

Mr. Alexander Noble was appointed an Examiner in Scotland, subject to the approval of the Privy Council.

REPORT OF THE BOARD OF EXAMINERS.

England and Wales.

June, 1871.

Examination.	Candidates examined.	Candidates passed.	Candidates failed.
Major	10	8	2
Minor	28	20	8
	38	28	10

Preliminary. One Certificate was received in lieu of this Examination.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be respectively granted a diploma stamped with the seal of the Society:—

Byles, James Henry..........London.
Churchill, Henry............Reading.
Lake, Richard..............Colchester.
Overton, Charles Arthur......Horncastle.
Pretty, Charles..............Birmingham.
Savory, Harry Banting......Painswick.
Walker, John Sydenham......Manchester.
Wing, Lewis................Torquay.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be elected Members:—

Savory, Harry Banting......Painswick.
Walker, John Sydenham......Beverley.

Resolved—That the following registered Chemists and Druggists be elected Members of the Society:—

Bagshaw, William..........Oldham.
Bass, James Thomas........Hemel Hempstead.
Campion, Robert............Harlow.
Coates, George Henry........Barlow.
De Witte, Henry Huskisson..Liverpool.
Gabriel, John Wild..........London.
Maunder, William..........Teignmouth.
Newbigin, James Leslie......Alnwick.
Rogers, Robert..............Plymouth.
Troke, Charles..............Stamford Hill.

Resolved—That the following, having passed their respective examinations, be elected Associates in business:—

MINOR.

Awbery, Albert Richard......Henley-on-Thames.
Sowray, Joseph............York.
Tomlin, Albert Roberts......Barnsley.

MODIFIED.

Barnett, Thomas James......Castle Hedingham.
Finch, Albert Henry........Swansea.

Resolved—That the following, having passed their respective examinations, be elected Associates of the Society:—

MINOR.

Baldock, James Thomas......Rochester.
Beach, Tom Clarke..........Great Malvern.
Bradley, William............Dudley.
Butcher, Henry............Sheffield.
Fegan, John................Exeter.
Fingland, William, jun.......Thornhill.
Goulden, Herbert............London.
Holme, William James......Bacup.
Hughes, James..............Swansea.
Jones, William Ellis........Barmouth.
Mills, Robert................London.
Rammell, Edward..........Crediton.
Rogers, John Maulden......Newport Pagnell.
Watmore, James............Wokingham.

Williams, Jabez Vivian ......Ramsgate.
Wood, Alexander............New Brentford.

MODIFIED.

Finch, Thomas..............Edinburgh.
Herbert, William............Southwark.
Johnson, Arthur ....Rotherham.
Mason, John.................Hastings.
Midgley, Charles............Bradford.
Spyer, Newton..............Watlington.
Turpin, Alfred Barritt ......Oxford.

Provincial Transactions.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

At a Council Meeting held in the library of the above Association on Friday, July 7, the following circular was ordered to be printed and circulated amongst the chemists of the Midland Counties:—

"Dear Sir,—At the last meeting of the Council of this Association it was resolved to endeavour to extend its operations and the sphere of its usefulness by taking more active cognizance of the various questions relating to trade and education which have especially arisen out of the Pharmacy Act of 1868, and by providing rooms in Birmingham for the transaction of the business of the Association, for the general purposes of a trade office, reading and club rooms, and for any other objects connected with the interests of chemists and druggists.

"The Midland Counties Chemists' Association is not without its records of useful services. Amongst these may be mentioned the successful influence (as the Council believe) which it has brought to bear upon the Government in the framing of the Petroleum Act, in a form which it is expected will be acceptable to chemists;—in the providing of excellent courses of lectures for students in chemistry and pharmacy, in the winter of 1869–70, and in the compilation of the Midland Counties Chemists' Price Book, which has had so much demand that a second edition is already issued. And yet, having regard to the important interests of the great midland district, the Council are conscious that the Association has not yet risen to the full position which it ought to occupy. Twenty years ago the 'Birmingham Pharmaceutical Institution' was second to none in the provinces, but since its decadence, associations of chemists in other great centres, such as Liverpool, Manchester, Leeds, Nottingham, Bristol, have conspicuously come to the front, and now maintain, with unabated ardour, their vigilant supervision of whatever relates to the interests and welfare of pharmacy. They have each their representatives in the Council of the Pharmaceutical Society in London, whilst the chemists of the Midland Counties of England and Wales, covering an area of more than 100 miles from east to west, or from north to south, with Birmingham for their commercial centre, do not possess a powerful organization, and do not now possess one representative at the London Board.

"It is with the intention of remedying this state of things that the Council of the Midland Counties Chemists' Association now makes an appeal to all chemists residing within the vast district of which Birmingham is the centre, to unite together in the formation of a vigorous Association. The passing of the Pharmacy Act of 1868 has imposed upon chemists the necessity of a higher education, which will in due course of time elevate the general character of the trade, and invest it with greater responsibilities. The provision of facilities for the education of young men in pharmacy, chemistry, etc. etc., is rendered easy in Birmingham, where appliances for this purpose exist in abundance. The Council of the Association invite young men, desirous of availing themselves of courses of lectures in aid of their studies, to communicate early with the honorary secretaries, who will give them information of the terms on which classes in connection with the Queen's College may be formed.

"Besides these just claims upon the services of such an Association as this, there are others affecting the privileges of chemists and druggists under the Pharmacy Act of which the Association will take cognizance. It is well known that there are persons who continue with impunity to sell poisons who are not registered under the Act, and who thus render themselves obnoxious to the law, but who, in the absence of any prosecutor, escape its penalties. All members of the Association are invited to report to the Council any cases of the evasion of the Pharmacy Act which they are able to substantiate, and measures will thereupon be taken to protect the privileges of its members in this respect.

"The Council will also make it their business to watch the various questions on which (like the present 'Amended Pharmacy Act,' now before the House of Commons) the expression of opinion throughout the country is so important. It may be here mentioned that the Council have sent one petition to Parliament on this question, and have set on foot another to be signed by individual chemists, praying Parliament to suspend the present Act until the recent 'recommendations' of the Pharmaceutical Council have been tried, or until all other dispensers of medicine in Great Britain are included in one measure of regulation.

"It will also be the duty of the Council of the Association at the next election of the Council of the Pharmaceutical Society, to insist upon the claims of Birmingham and the Midland Counties to one seat (at least) on the Board in London, of which this district has been deprived by the action of other Associations.

"The offices of the Association, which are now open at the Quadrant Chambers, Birmingham, are furnished with the nucleus of what it is hoped will become a useful library of reference and research for chemists in all questions affecting their trade occupation, and for assistants desirous of qualifying themselves for the examinations. Periodicals are laid upon the table, and there is accommodation in the rooms for the reception and display of any trade novelties which manufacturers or firms in business may desire to bring under the notice of druggists; the only condition required in sending such articles being that they shall become the property of the Association, and be sent carriage paid.

"Meetings of the Association will be held in these rooms on the first Friday in each month, at three o'clock P.M., for the transaction of business. All members throughout the Midland Counties are earnestly invited to attend these meetings, and to support them by their influence. The rooms will be freely at the service of all assistants and apprentices (members of the Association), where they may hold meetings, read original papers, and use them for the purposes of a club. The rooms will be open from 10 A.M. to 10 P.M. All chemists (members of the Association) and their friends are invited freely to make use of the accommodation they afford by making it a general rendezvous, chemists' exchange, club room, reading room, writing room, house of call, etc. etc., and a place of neutral ground for meeting trade travellers, for whose samples, if desired, one of the rooms may be occasionally engaged.

"It remains only to add, that to promote these varied objects, an increase of the income of the Association is necessary. At present 102 gentlemen are members of it. It will need an increased number of members and of subscriptions to maintain the objects in view efficiently. The *minimum* subscription is 5*s*. per annum for principals and 2*s*. 6*d*. per annum for assistants and apprentices of chemists. Many voluntary subscriptions, however, on a more liberal scale, are already offered and made, as well as liberal donations towards the preliminary expenses of the offices."

A vote of thanks was passed to the Council of the Pharmaceutical Society for a grant of £10 in aid of the library fund.

Proceedings of Scientific Societies.

THE GENERAL MEDICAL COUNCIL ON PHARMACY AND THERAPEUTICS.

On Thursday, the 6th inst., this body met under the presidency of Dr. PAGET. The subject before it was the recommendations of the Committee on Education. Dr. PARKES, in bringing these forward, proposed, first: "That it is desirable that instruction in pharmacy should be separated from that in therapeutics, and that the former should be attended at an early, and the latter at a later, period of the medical curriculum." The Council, he remarked, had much reason to be satisfied with the influence produced by the reports of the visitors of examinations and the report of the Committee on Professional Education in 1869. The licensing bodies had adopted all the more important of the suggestions made to them. This was but natural, as the suggestions had been well conceived, and had been met by the licensing bodies in a proper spirit. As to the proposal now before the Council, he said that it was obvious that instruction as to the drugs used in medicine, and the means of compounding them, should be separated from instruction as to their use, which could be adequately understood only when the student had attended courses on physiology, medicine and surgery. The majority of the more experienced teachers of these subjects had, in the Committee's Report of 1869, strongly recommended the teaching of pharmacy at a different stage of the medical curriculum from the teaching of therapeutics. Dr. Christison, whom the Council should respect as much as any English or European authority, had expressed himself strongly in favour of the proposed separation. Dr. Aquilla Smith had given the same opinion. The educational report had recommended that the teaching of pharmacy should be made more practical and tutorial than hitherto; but this was a point for the licensing bodies to deal with. That such a plan, however, was desirable was proved by the manner in which the course was carried on in the University of Aberdeen. Dr. Harvey, the professor there, might publish his account of the course with advantage; while Dr. Macrobin, the member of Council for that University, would corroborate his opinion as to the satisfactory working of the plan.

Dr. CHRISTISON seconded the motion. The defects of the present system he had been the first to see, and the first to suggest its improvement. Materia medica had formerly a very comprehensive signification, including the natural history and character of medicines, and the mode of preparing them for use; their action, so far as it was known, and the diseases to which they were applied, to which was afterwards added the subject of dietetics as a remedy. For a long time materia medica continued to be so understood in Scotland, whose seats of learning borrowed the system very largely from the Dutch school. Materia medica, however, was not now regarded in the same way; and he was much surprised, on engaging in his present professorship, to find that the London Apothecaries' Society gave it a totally different meaning. The students were required to attend a course on this subject the first year. Now, materia medica, properly understood, could not possibly be studied in the first year. The more important parts of it could be taken up only at an advanced period. On making inquiry he found, what the shortness of the London course had led him to suspect, that it was almost always only a course of pharmacy. It was sometimes argued that the branch of pharmacy having attained such perfection in the hands of pharmaceutical chemists, practitioners might leave the subject unstudied. It appeared to be forgotten, that in many parts of the country, medicines were not to be obtained from a chemist but only from the practitioner, who ought, therefore, to know their distinctive characteristics. The subject should be studied practically as well as by lectures. This, however, was not always possible. Edinburgh University lacked (in the mean time, at least) the requisite accommodation. In a good practical dispensary the students could be well taught in a body, if there was adequate accommodation. It was not necessary that the patients should swallow all the prescriptions made up by the students. The subject might be taught in a short time, so as to obviate the necessity of the student obtaining instruction at a chemist and druggist's, which was now generally required when an apprenticeship had not been served. Thus the student's work would be really lessened. Of course the period of study should be early,—after chemistry and botany. With regard to therapeutics, some persons thought it beneath consideration. This was partly due to the way in which it had been taught. He declined to say anything specific on that subject; but he knew that in many schools therapeutics had been greatly neglected. The subject might be made highly attractive; and it included many points beyond the sphere of the lecturer on the practice of medicine, unless he went far out of his way. Therapeutics, as a course, should come near the end. It was most important in giving effect to the other branches. Without it the most accurate diagnosis would be incomplete.

Dr. MACROBIN supported the motion.

Dr. HUMPHRY moved, and Dr. APJOHN seconded, as an amendment, "That practical instruction in pharmacy may, with advantage, be substituted for formal lectures on the subject, and should be attended at an early period of the professional curriculum; and that instruction in therapeutics should be conducted at a later period of the professional curriculum, either by a special course of lectures, or as an essential part of the course of lectures on medicine and surgery."

Dr. ANDREW WOOD and Dr. AQUILLA SMITH supported the original proposal and criticized the amendment. Ultimately, after a desultory and slightly acrimonious discussion, Drs. Parkes and Christison carried their point by a decisive majority.

Parliamentary and Law Proceedings.

HOUSE OF LORDS.

PETROLEUM BILL.—*July* 7.—The report of amendments in the Petroleum Bill was brought up and agreed to.

NITRO-GLYCERINE ACT (1869).—*July* 10.—The Earl of Shaftesbury presented a petition from proprietors, managers, miners and others interested and employed in ironstone mines at Whitehaven, praying that so much of the Nitro-Glycerine Act of 1869 as extends its provisions to dynamite may be repealed, or that an Act may be passed declaring that dynamite shall be excluded from the operation of the said Act, and that dynamite and all other explosives used in mines and quarries may be placed on the same footing and subject to the same restrictions as gunpowder is now by law subject to.

HOUSE OF COMMONS.

Pharmacy Act (1868) Amendment Bill.—*July* 10.—Petitions against this Bill were presented from—

Chichester, by Lord H. Lennox.
Congleton, by Mr. W. Egerton.
Harwich, by Colonel Jervis.
Launceston, by Mr. Lopes.
Lewes, by Lord Pelham.

July 11.—Petitions against the Bill were presented from—

Biggleswade, by Mr. A. Russell.
Caistor, by Mr. R. Winn.
Gloucester, by Mr. Price.
Great Yarmouth, by Sir E. Lacon.

July 12.—A petition against the Bill was presented from Peterborough, by Mr. Whalley.

Nitro-Glycerine Act (1869).—*July* 7.—A petition from Whitehaven was presented by Mr. C. Bentinck to the same effect as that mentioned above (House of Lords).

Poisoning of Seventeen Children by Calabar Beans.

An incident is reported from Liverpool, which, apart from the large number of children injured, is remarkably similar to one that occurred in the same town seven years since, and reported in this Journal.*

On Monday last seventeen children, who with others had been playing on some waste ground in Boundary Street, where a quantity of rubbish—probably the sweepings of a ship or warehouse—had been deposited, were found to be suffering from the effects of poison. Amongst the rubbish the children had found a quantity of Calabar beans, some of which they had eaten. Eleven of the children were taken to the shop of Mr. Smith, druggist, in Athol Street, who immediately administered emetics and rubbed their chests with spirits of turpentine. Medical assistance was obtained, and these and the other children were pronounced to be out of danger the same evening.

The police have not yet discovered whence the rubbish came, or who were the persons culpable in depositing it in a public place. Three loads of the rubbish were at once removed, and buried in a pit covered with clay.

Poisoning by Prussic Acid.

An inquest has been held in Liverpool on the body of Samuel Hudson, aged 40. It appeared from the evidence that the deceased was eccentric, nervous and irritable in manner, and in the habit of drinking. Latterly he seems to have been in money difficulties and depressed in his mind. On Saturday morning he went to Messrs. J. H. and S. Johnson's, druggists, Church Street, and asked for an ounce bottle of prussic acid. He said that he wanted it for photographic purposes, and requested that it might be put into a peculiar-shaped bottle. Being a customer to the firm, and not appearing otherwise than usual, he was served with the prussic acid. The same afternoon a workman employed by him found him lying dead in his workshop.

Dr. W. J. Morris, from the Southern Dispensary, made a *post-mortem* examination of the body, and found that death had resulted from prussic acid, there having been more taken than would be certain to destroy life.

Verdict—"Died from swallowing prussic acid, but how administered there was not sufficient evidence to show."

* 2nd Ser., Vol. VI., p. 134.

Alleged Poisoning by Arsenic.

Much excitement prevailed at Cambridge on Monday last, owing to the exhumation of a man named Day, and the further examination of the widow of the deceased, who was reapprehended on Saturday in consequence of the detection of poison in a pudding on a second analysis made by Professor Liveing. The body was exhumed early in the morning, and the portions of it required by Dr. Letheby were sent to London in charge of an officer. At the police-court the town-clerk stated that since the last occasion of the woman appearing in court, Professor Humphry, Dr. Pagett and Professor Liveing had been consulted, and they were now awaiting the report of Dr. Letheby, but sufficient additional evidence would be given for a remand.

Professor Liveing, Professor of Chemistry in the University of Cambridge, said that he made an analysis of the pudding before the day of the adjourned inquest, but detected no poison. On Saturday last he made a further analysis of another part, and found some arsenic.

The prisoner, who said that she was innocent and did not put anything into the pudding, was remanded.

Obituary.

THOMAS HAWKES TANNER, M.D.

Medicine has lost an able and zealous practitioner in Dr. T. H. Tanner, who died at Brighton on the 7th inst., at the early age of forty-six. Dr. Tanner was educated, we believe, at the Charterhouse and King's College, London; becoming a member of the Royal College of Surgeons of England in 1847, and graduating as Doctor of Medicine at St. Andrew's in the same year. His career will hereafter be cited as one of the first in which success was attained not by reputation won at hospitals or societies so much as in the pages of medical journals and of publications addressed to the student and the general practitioner. His works, most of which were enlarged from their original tiny dimensions to stout octavos, enjoyed immense popularity with the candidate for examination and the "run-and-read" physician. They were remarkable for the skill with which their author worked down the latest results of science to undergraduate apprehension or to general practice, and were the means of winning him a professional name, which he was rapidly raising in the esteem of his brethren when death removed him from his wide circle of patients and friends.

DR. A. KEITH JOHNSTON.

The author of the 'National Atlas,' and still more of the 'Physical Atlas,' deserves a passing notice at our hands. Dr. A. Keith Johnston died on Sunday at Ben-Rhydding, in his sixty-seventh year. He was trained for the medical calling in Edinburgh, the city of his birth. Wisely, however, he devoted himself to the science of geography, in its largest sense; and in 1843 gained the applause of the learned at home and abroad by his 'National Atlas,' a work which cost him fifteen years' research in the geographical literature of nearly every European tongue. This was succeeded by his 'Physical Atlas,' which, suggested by Berghaus, superseded that geographer's work by its fulness and accuracy of information on the geology, meteorology, climatology, hydrography, magnetism, etc., of the globe, with the vegetable and animal kingdoms which inhabit it. A member of every geographical society of note throughout the world, he took an active interest in the meteorological and epidemiological societies. He did much for medical geography; and only a few weeks before his death he received the Royal Geographical Society's medal in token of that body's appreciation of his services. Greatly esteemed in private and public, he goes down to the grave with the honour of having done more for geography, from its humblest educational up to its highest scientific aspects, than any man of his time.

The Amended Pharmacy Bill.

Sir,—Mr. Forster will ask the House of Commons on Monday next to vote the principle of the Bill for the amendment of the Pharmacy Act. There is time to say a word on this principle and the form of procedure adopted by the Government on this occasion.

The intention of the Pharmacy Act, 1868, we may all agree at the outset, was to ensure the public safety. On its spirit, or mode of fulfilling that intention, the Privy Council and our body are of opposite opinions; the former stating that it should be carried out by mechanical arrangements, whilst we insist that the spirit of the Act is educational, and attains its result by educating chemists for their business. On this point Mr. Forster agrees with us; having stated to the first and second deputations of the Council that if all chemists possessed the same educational qualifications as the gentlemen present, no regulations would be necessary. He also stated at the last interview that he had answered a letter received from Mr. Schacht to the same effect.

On these repeated assertions we found the justice of our claim for non-intervention. It is a narrow issue, and we raise it on the question. We are daily adding to our ranks those only who give proof to our examiners and to the Government assessor of their fitness for their calling, and will not this legislation permanently affect them? The Bill, as first drawn by the Privy Council, was pressed forward in the House of Lords with all the momentum of a Government measure. The first intimation the Council received of such a Bill existing was a summons to attend a special meeting for the purpose of considering a Bill which had been read a second time in the House of Lords the previous evening.

This was an act of injustice to the Pharmaceutical Council, and one of discourtesy to the Peers, inasmuch as discussion on the second reading was balked. *Inter alia,* the Lords were not permitted to be informed of the attempted design by the Privy Council to impose upon the trade, by a side-wind, that peculiar bottle which in 1868 they had formally condemned, and which Lord Salisbury had freely attacked as involving a principle of legislation alien to the spirit of laws which should prevail in this country.

A Bill started so unfairly could not escape rude checks in its course. It was found to be merely a Bill of pains and penalties, so unable to endure the touch of criticism, that when brought face to face with public opinion the Privy Council was fain so far to alter its provisions as to virtually constitute it a new Bill. Thus the House of Commons judged when it met the motion for the second reading by cries of "withdraw" too general to be disobeyed by the Minister.

The House of Lords had thus, by listening to the representations of Government, sanctioned by their vote a Bill which its authors were compelled within a month materially to change. Not a considerate or respectful manner of treating that assembly! Mr. Forster says such a course is not unusual; and we say perhaps the great suspicion and the hostile votes that assembly has so repeatedly of late bestowed on Government measures may be read by the light of this transaction.

The Government having thus, in the face of Mr. Forster's expressed opinion, disregarded the spirit of the Act, 1868, viz. that the calling of a chemist and druggist is a responsible one, and those following it should be educated to fulfil its duties, has floundered in a sea of difficulties. In attempting to remove anomalies which were inherent to their Bill, their amendments, or, more properly, their new Bill, violates the spirit of the Act which they allege it supplements. Of what offence has the medical profession been guilty that both the Act of 1868 and Dr. Brewer's Amended Act should be violated? In these Acts clauses specially exempt medical men from interference; the present Bill seeks to impose upon them the present and all future regulations which the Pharmaceutical Council and the Privy Council may deem proper to impose; and, although the present Bill restricts its operation to those keeping open shops, it may, if allowed to go into committee, come out in a form scarcely recognizable to any of us. Perhaps some logical mind in committee will urge that a medical man is the best judge how he shall conduct his business, another that if any are to be under this Act, why not all,—hospitals, dispensaries, private surgeries?

We as a body declare that regulations which we objected to for ourselves are not more acceptable because imposed upon others. We have not yielded to the tempter, who says in effect, You think my proposals evil, but now you can more gracefully yield to my solicitations, for I have the same intentions towards your sister. We reply, that acquiescence in such a proposal, and for such a reason, would only add to the family disgrace.

The Government, catering for support to its Bill, has sought by such a proposition to disarm the opposition of chemists; and a letter recently sent to members of the trade shows that these means have not proved wholly unsuccessful.

The poison bottle is cast overboard,—what policy can guide the Privy Council? A short time since it was insisting that the public safety demanded the adoption of such a bottle; now it leaves the public safety to shift for itself without it. Did it find that, like its proposal to regulate the dispensing of poisons in single doses, it would not quite do? or is it that, failing to secure that amount of support it calculated upon in the House of Commons, it now comes forward, having re-adjusted its Bill, dropping the bottle on one side and picking up the surgeons on the other? We are told these concessions are proposed by the Government as a compromise to answer our objections to some details of the Bill. The time for compromise would have been more gracefully chosen before the threatened defeat of the whole measure; and if compromise be the right principle upon which to act, until how recently has the Privy Council been wanting in it?

The fact is, our great strength in this conflict has been the disapprobation of such attempted over-legislation by a Government department entertained generally by the members of the House of Commons. We watch very jealously in this country any attempt at bureaucratic government. The powers of the Privy Council are great, and for that reason are the more jealously watched; otherwise, following the natural tendencies of unelected bodies, its irresponsibility would lead it into abuses not inconsistent with its name, which would cause it to become in time the Star Chamber of the nineteenth century.

It is only an inexpressible awe for any communication from the Privy Council that can explain the attitude taken by preceding Councils. They have proved to be made of very squeezable materials—swayed now by those letters from the Privy Council Office, now by the opposition of their constituents, now proposing to the Privy Council regulations for storing poisons, now at the bidding of that body adding the poison bottle; then proposing these regulations to the trade, then voting them as recommendations; and, lastly, at the annual meeting not concealing their desire, if they did not vote, for giving these regulations the force of law. They have been actuated by the policy of making things pleasant all round; but, like the old man and his ass, they have "tried to please everybody and pleased nobody."

Strengthened by the confidence and support of the great body of our trade, the present Council has dropped this india-rubber policy. The only pressure they should answer to is that of public opinion; and so long as that speaks in favour of an opposition to the principle of this Bill, so long ought they to endeavour to destroy it, by every means their office affords.

S. C. Betty.

The Report of the Special Committee.

Sir,—In the Journal of July 8th you publish the returns forwarded by local secretaries as to petitions against the Pharmacy Bill. Under Brighton I find it stated, number of chemists and druggists in town 52, and number of signatures obtained 52.

If this is intended to convey the impression that all the Brighton chemists signed this petition it is, as far as I am concerned, incorrect. I am a Brighton chemist, and neither have I, nor do I intend, to append my signature to such a document.

In inserting these lines in your next number, you will greatly oblige

J. Schweitzer.

[*** These returns were furnished by the Committee.—Ed. Pharm. Journ.]

Sir,—In the recent returns requiring the numbers of those who signed against Mr. Forster's Bill, and also the number of chemists in the respective towns, opposite Brighton was 52, in each case. This has led to an erroneous conclusion, which I am desirous of rectifying. All that I saw readily signed the petition, but as some were out their names did not appear. Others, however, on the register, but not in business on their own account, signed, which seemed to me in number equal to those that were out. Subsequently, on going more carefully through the names, I find 56 chemists in Brighton in business. I have heard that one of the absent ones was opposed to the petition, and therefore, in justice to him and the other three whom I did not see, this explanation is due.

July 11*th*, 1871. W. D. SAVAGE.

Sir,—The tabulated return of chemists and druggists is very much calculated to mislead, so far as Kingston-upon-Hull is concerned, and therefore I must ask you to permit me to explain to those it may interest that while the number of persons on the register is 124, the actual number of chemists in business, as nearly as I can ascertain, is 90, all of whom have signed the petition against the new Pharmacy Bill, with one exception.

Please insert this in next issue of PHARMACEUTICAL JOURNAL.

Hull, July 11*th*, 1871. FRANCIS EARLE.

Sir,—In the list of petitions in your last number I notice an error regarding the Newcastle petition. I stated that there were about 70 chemists in Newcastle, and that the petition was signed by the chairman and secretary of the meeting, according to its unanimous vote.

BARNARD S. PROCTOR.

Newcastle-on-Tyne, June 11*th*, 1871.

A CONFERENCE QUESTION.

Sir,—In Saturday's Journal there is a letter, of which you take notice, from "A Conference Man," regarding certain arrangements in connection with the annual meeting of the Conference shortly to be held here.

The suggestion made by your correspondent, "Would it not be better to make a special arrangement with a first-class hotel?" etc., is not only a good one, but doubtless an idea possessed by many members of the Association. Let me, however, say that at this particular season of the year it is impossible to secure, so long beforehand, such accommodation. No hotel here will engage rooms for the forthcoming meeting, while many state they expect numerous demands from former visitors at this season, so that they are unwilling thus early to fix for any number of rooms.

Those having apartments to let as lodgings seemingly show the same feeling, and, so far as my exertions have gone in this direction, I have been very much discouraged.

That it would be a very agreeable thing for our members to congregate in one large hotel is undoubted, but the difficulties ahead may be shortly noticed.

1. Who could tell how many rooms to engage and become answerable for? We have nearly 1900 members, how many will come to Edinburgh?

2. From the middle of the present month on till October the constant influx of strangers to this place is almost inconceivable.

3. Not only do the pharmaceutical gentlemen require accommodation, but the members of the British Association are also expected at this very period in considerable numbers.

Reasons 2 and 3 are as well known to those having rooms to let as to us, and they can therefore be quite independent until nearer the time.

However, I can faithfully promise that if any parties will send me a special request and authority to engage rooms, I will be most happy to do all I can to fulfil their desire, and will get as many in one hotel as I possibly can.

I may mention, in illustration of the difficulty referred to, that one house, having 150 bedrooms to let, on my expressing to the landlord a desire that he would promise me a certain number, replied, "I cannot do this, as we will have more than 150 American visitors just about the very time you would require those rooms."

I may, however, shortly remind those intending to honour Edinburgh on this occasion, that on Tuesday evening we have our conversazione; on Wednesday evening there will be the introductory address of the British Association; on Thursday evening the public dinner of the Conference will take place; while throughout Monday, Tuesday, Wednesday and Thursday the Craigie Hall, 5, St. Andrew Square, will be open from 9 till 6 as a reception room, where some one will be constantly in attendance to give any information which may be required.

JOHN MACKAY, *Hon. Sec.*

119, *George Street, Edinburgh,*
July 11*th*, 1871.

POISON BOTTLES.

Sir,—Seeing in your last issue two letters concerning poison-bottles, each adopting a method of fixing the cork or stopper, I beg to ask how many chemists would take the trouble to remove a fastening before they could get at the contents of the bottle, and the few who would do so, would they all replace it after use? If not, it would be of little value.

I suggest a small bell attached to the neck of each bottle, which would not give extra trouble, and could be seen, felt and heard on taking up the bottle to get at the contents. I hope this suggestion may prove useful from

"ALARM BELL."

THE 'GRAPHIC' ON POISON REGULATIONS.

Sir,—I beg to call your attention to a short article in the *Graphic* of July 8th, respecting a case of poisoning at the Islington Dispensary, in which Kino powder was given for rhubarb and soda. *Mr. Graphic* seems to blame the chemist, and not the dispenser at the dispensary, for not having his packets properly labelled. Are we to put up with this, I ask you? Does not such an article make the public shudder, and drive them from the doors of a chemist, consequently injuring his trade? Ought not *Mr. Graphic* first examine the chemist's drawers, and see for himself if the packets or powders are properly labelled? Or where can he find one chemist in fifty or a hundred who keeps kino powders ready weighed up?

I consider it very hard that chemists should have to carry the cargo of mistakes made in public dispensaries. I think some, at least, of your readers will agree with me. I hope some one more able than I will bring the case before *Mr. Graphic*, and explain to him the difference between a chemist's establishment and that of a dispensary.

Bath, July 10*th*, 1871. "FAIRPLAY."

E. Marshall.—Prussiate of potash is not a metallic cyanide within the meaning of the Act, neither is it a poison.

"*Calyx.*"—'The Journal of Botany, British and Foreign,' edited by Dr. Seemann, assisted by Dr. Trimen and Mr. J. Baker, and published at 10, Little Queen Street, Lincoln's Inn Fields, W.C.

"*Associate.*"—The work is out of print, but second-hand copies may sometimes be met with.

Robert Stewart.—(1.) 'Pharmacopœa Borussica,' editio septima, 1862. (2.) See Vol. I. p. 995.

W. L. Scott.—Our correspondent's letter, as far as we are able to read it, contains nothing beyond what we have already published on the subject referred to.

We are compelled, from want of space, to defer the publication of several communications.

The following journals have been received:—The 'British Medical Journal,' July 8; the 'Medical Times and Gazette,' July 8; the 'Lancet,' July 8; the 'Medical Press and Circular,' July 12; 'Nature,' July 5; the 'Chemical News,' July 8; 'Gardeners' Chronicle,' July 8; the 'Journal of the Society of Arts,' July 8; the 'Grocer,' July 8; 'Produce Markets Review,' July 8; the 'English Mechanic,' July 7; the 'Canadian Pharmaceutical Journal' for July; 'Journal de Pharmacie et de Chimie' for February and March.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. R. D. Mitchell, Mr. J. Birt, Mr. F. V. Ballard, Mr. T. Brewis, Mr. A. W. Postans, Mr. A. H. Mason, Mr. J. Addison, Mr. A. T. Brenner, Mr. E. J. Beale, Mr. M. C. Cooke, Mr. J. Abraham, J. S., W. H. B., S. W. N., T. P. B., C. D. C., E. H., R. S., "Chemicus," "Fair Play," "Theta."

NOTES ON SOME EASTERN VARNISH-TREES.

BY JOHN R. JACKSON, A.L.S.,
Curator of the Museums, Royal Gardens, Kew.

"We sell six sorts of varnish; to wit, the dry varnish, which is made of oil of spike, fine turpentine, and sandarac melted together. The second is white varnish, call'd Venetian varnish, which is oil of turpentine, fine turpentine and mastick melted together. The third is spirit varnish, which is compos'd of sandarac, white karabe, gum elenic and mastick. The fourth is golden varnish, which is of linseed oil, sandarac, aloes, gamboge and litharge of gold. The fifth is China varnish, which is of gum lac, colophony, mastick in tears and spirit of wine. The sixth is common varnish, which is nothing else but common turpentine dissolv'd in oil of turpentine, as observ'd speaking of turpentine before. There is another varnish, some of the religious make; but, as we do not deal in it, I shall not trouble my self or the reader about it. As to the use of varnish that is best known to the workmen, whose business it is to deal in the several sorts, whereby they understand which is the properest for their particular use."

So wrote Pomet in his 'Compleat History of Druggs,' published in 1725. Since that time, we have not only added to the list of compound or manufactured varnishes, but discovered other natural exudations which are generally known as varnishes. Two useful Indian varnish-producing trees are the *Melanorrhœa usitatissima*, Wall., and the *Holigarna longifolia*, Roxb. They both belong to the Natural Order *Anacardiaceæ*. The former is a large, hard-wooded forest-tree, found growing from Tenasserim and Pegu to Munnipore. To collect the varnish with which the tree abounds holes are made in the trunks, and pieces of bamboo, closed at the lower ends, inserted. These bamboo pipes are left for a day or two to fill. The juice, as it flows from the tree, is white, but it becomes black by exposure to the air. In order to preserve it for use it has to be kept in water. It is very extensively used by the natives for varnishing or lacquering all kinds of household articles, furniture, etc. The juice of *Holigarna longifolia*, which is also a large tree, is likewise collected and used as varnish by the natives of Malabar. It is very acid, and, like that of *Melanorrhœa*, will raise blisters or swellings if applied to the skin. Another, and certainly the most interesting, of the Anacardiaceous varnish-producing trees is a species of *Rhus*, a genus of some notoriety, inasmuch as some of the American species, as *R. venerata* and *R. Toxicodendron*, are reputed to have caused such extraordinary effects of poisoning from the mere handling of any portion of the plant, that they have become almost as familiar as the Upas tree of Java. The varnish-producing species to which we have alluded is *Rhus vernicifera*. It is a small tree, native of Japan, and yields, it is said, the best varnish or lacquer, in the use of which the Japanese are, and have been, so famous. The tree is very extensively cultivated in many parts of Japan, and yields, besides varnish, a quantity of wax. One product, however, suffers at the expense of the other, for if the trees are tapped for the sake of the lacquer, which is usually done before they come to full maturity,—some have said at the age of three years,—and which frequently ends in the death of the tree, no wax can, of course, be obtained. In some districts, where a higher value is set upon the wax than upon the varnish, the extraction of the latter is prohibited. At the time of collecting, the varnish is about the thickness of cream, and of a lightish colour, changing to black, and becoming thick by exposure. It is cleared from impurities by straining: at one time very fine paper was used for this purpose.

Of the mode of preparing it for use, nothing certain seems to be known. The old Japanese lacquer ware was far superior to that of the present day, and it is said that the ancient mode of preparation has been lost to the modern Japanese. Some travellers, however, tell us that if the varnish is used in its pure state it is very clear, and every mark or grain of the wood upon which it is laid is distinctly visible; but the natives frequently mix with it other materials, such as finely-ground leaf-gold or pulverized charcoal, which, of course, renders it opaque, and with which they produce various designs. The Japanese use it for varnishing many of their articles of household furniture.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.
DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

LIQUOR CALCIS.

[§ 438 grams require for neutralization at least 20 cub. centims. of the volumetric solution of oxalic acid.]

100 cub. centims. of the volumetric solution are neutralized by $\frac{1}{10}$ of half a molecule of lime, or $\frac{56}{20} =$ 2·8 grams; therefore in 438 grams there would be $\frac{1}{5}$ of this, or ·56 gram of Ca O.

Lime water exposed to the air gives a deposit of carbonate. Very distinct crystals are sometimes produced in this way when, as in an imperfectly-stoppered bottle, the carbonic acid gas has been admitted very gradually.

LIQUOR CALCIS CHLORATÆ.—For the quantitative test, see CALX CHLORATA.

LIQUOR CALCIS SACCHARATUS.

This solution contains 1·54 per cent., or almost exactly twelve times the amount of lime in ordinary lime water. If heated, it deposits a compound of lime and sugar, $3\,CaO\,.\,C_{12}H_{22}O_{11}$, which redissolves on cooling.

LIQUOR CHLORI.

Chlorine gas is generated by the action of hydrochloric acid on black oxide of manganese.

$$MnO\,.\,O + 2\,HCl + 2\,HCl$$
$$= MnCl_2 + Cl_2 + H_2O + H_2O.$$

Chloride of manganese remains in the generating flask. The chlorine gas is passed first through a little water to wash it, and then into the water in which it is to be dissolved. The solution is to be kept in the dark, since under the influence of light chlorine decomposes water, with production of hydrochloric acid and evolution of oxygen.

[§ A yellowish-green liquid, smelling strongly of chlorine, and immediately discharging the colour of a dilute solution of sulphate of indigo. Evaporated, it leaves no residue.] Mixed with iodide of potassium in excess, it gives free iodine, which requires for the discharge of its colour an amount of the volumetric solution of hyposulphite of sodium corresponding to 0·6 per cent. of chlorine.

For a comparison of the properties of chlorine, bromine and iodine, see Vol. I. p. 526.

Equal volumes of hydrogen and chlorine gases weigh respectively 1 and 35·5. Chlorine is therefore a very heavy gas. Its specific gravity, taking air as unity, is $35·5 \times ·0693 = 2·46$. If, therefore, chlorine gas is required, it is usually collected by allowing it to run from the delivery tube into a bottle, from which it displaces the air. Chlorine dissolves in about half its volume of water; with a small quantity it unites to form a crystalline hydrate. Its great affinity for hydrogen causes it to decompose almost all organic bodies by removing that element from them. It combines with an equal volume of hydrogen gas to form hydrochloric acid gas. The combination occurs instantly with explosion when the mixed gases are exposed to sunlight.

Liquor Ferri Perchloridi Fortior.

Iron wire is first dissolved in hydrochloric acid so as to give solution of ferrous chloride.

$$2HCl + Fe = FeCl_2 + H_2.$$

This is filtered, mixed with a further quantity of hydrochloric acid and some nitric acid. The liquid thus obtained is nearly black from the retention of the nitric oxide gas produced by the decomposition of the nitric acid. On boiling briskly there is a sudden evolution of a gas which gives red fumes as it escapes, and the liquid then assumes a clear orange-brown colour.

$$\underset{\text{Ferrous chloride.}}{6FeCl_2} + \underset{\text{Hydrochloric acid.}}{Cl_6H_6} + \underset{\text{Nitric acid.}}{2(NO.O.HO)}.$$

$$= \underset{\text{Ferric chloride.}}{3Fe_2Cl_6} + \underset{\text{Nitric oxide gas.}}{2(NO} + \underset{\text{Water.}}{H_2O} + \underset{\text{Water.}}{H_2O)}.$$

[§ Diluted with water it is precipitated white by nitrate of silver, and blue by yellow prussiate of potash; but not at all by red prussiate of potash.] These tests indicate its character as a chloride and as a ferric salt; the third that it is free from ferrous chloride. It is apt sometimes when carelessly prepared to contain nitrate; this can be destroyed by well boiling with a little more hydrochloric acid.

Liquor Ferri Pernitratis.

Iron wire is dissolved in nitric acid diluted with water so as to moderate the action. The solution is then filtered and made up with distilled water.

The reaction which takes place is as follows :—

$$\underset{\text{Iron.}}{Fe_2} + \underset{\text{Nitric acid.}}{6(NO_3H)} + \underset{\text{Nitric acid.}}{2(NO.O.HO)}.$$

$$= \underset{\text{Ferric nitrate.}}{Fe_2(NO_3)_6} + \underset{\text{Nitric oxide gas.}}{2(NO} + \underset{\text{Water.}}{H_2O} + \underset{\text{Water.}}{H_2O)}.$$

It is therefore parallel to that which occurs in the case of the perchloride.

This solution gives also a blue precipitate of Prussian blue, Fe_4Fcy_3, with yellow prussiate; but no precipitate with red prussiate of potash.

Liquor Ferri Persulphatis.

Sulphate of iron is dissolved in water mixed with the proper quantity of sulphuric acid; to the solution nitric acid is added, and the black liquid boiled till after the disengagement of the nitric oxide gas, the liquid becomes clear red.

$$\underset{\text{Ferrous sulphate.}}{6FeSO_4} + \underset{\text{3 molecules of sulphuric acid.}}{(SO_4)_3H_6} + \underset{\text{2 molecules of nitric acid.}}{2(NO.O.HO)}.$$

$$= \underset{\text{Ferric sulphate.}}{3Fe_2(SO_4)_3} + \underset{\text{Nitric oxide gas.}}{2(NO} + \underset{\text{Water.}}{H_2O} + \underset{\text{Water.}}{H_2O)}.$$

The solution gives the same reactions with the red and yellow prussiate of potash as the two last.

In one fluid-drachm of each of these solutions there are the following quantities in grains :—

Liq. Ferri	Perchlor.	Pernit.	Persulph.
Iron .	10·94	1·82	8·00
Peroxide of Iron (Fe_2O_3)	15·62	2·60	11·42
Approximate ratio—	6	1	4·4

Liquor Hydrargyri Nitratis Acidus.

The mercury dissolved in cold, slightly diluted, nitric acid gives mercurous nitrate.

$$\underset{\text{Mercury.}}{6Hg} + \underset{\text{Nitric acid.}}{6NO_3H} + \underset{\text{Nitric acid.}}{2(NO.O.HO)}.$$

$$= \underset{\text{Mercurous nitrate.}}{6HgNO_3} + \underset{\text{Nitric oxide.}}{2(NO} + \underset{\text{Water.}}{H_2O} + \underset{\text{Water.}}{H_2O)}.$$

And then on boiling the solution with the excess of acid as directed, the mercurous is converted into mercuric nitrate.

$$\underset{\text{Mercurous nitrate.}}{6HgNO_3} + \underset{\text{Nitric acid.}}{6NO_3H} + \underset{\text{Nitric acid.}}{2(NO.O.HO)}.$$

$$= \underset{\text{Mercuric nitrate.}}{6Hg(NO_3)_2} + \underset{\text{Nitric oxide.}}{2(NO} + \underset{\text{Water.}}{H_2O} + \underset{\text{Water.}}{H_2O)}.$$

The B. P. tests indicate that it is a mercuric nitrate (yellow precipitate with potash) free from mercurous salt (no precipitate with dilute HCl).

CUNDURANGO.

BY THOMAS ANTISELL, M.D.

In the month of March of this year, Mr. Flores, Minister of Ecuador at Washington, forwarded a box containing a vegetable medicament which he had received from his government for presentation to the State Department, and requested that some analyses and experiments might be made with it, to test its medicinal value. The samples of the drug were stated to have grown in the province of Loja, Ecuador; and extracts from the official journal accompanied the parcel, showing that great medicinal virtues were attributed to the wood and bark of the tree known as *Cundurango*. The extracts were testimonials from Doctors Cæsares and Eguigureu of that province, as to its great value in cancer, fungus, hæmatodes and constitutional syphilis. These statements were supported by a letter from Mr. Rumsey Wing, the United States minister resident at Ecuador, to Hon. H. Fish, Secretary of State, testifying to the medicinal virtues of the plant as admitted by the natives of Loja, in which he mentions that a decoction of the fruit is known to be a poison, and that the parts of the plants used medicinally are the bark and leaves.

During the month of April a sample of the plant (small branches) was received at this Department from Hon. Mr. Fish, with the request to have an analysis made and reported to him for the benefit of the Ecuador government. Meanwhile, the plant itself had been tried, in the form of a decoction, upon some patients in this city affected with cancer, and with apparently considerable relief to the sufferers.

About one pound and a quarter in weight were received for analysis.

The sample consisted of stem and branches of apparently a shrub, but was unaccompanied by leaf or root, so that the botanical characters of the plant could not be determined.

The stem is woody, and covered by a greenish or ash-grey bark, the former tint being due to the lichens on its surface; the branches are from half an inch to a little over an inch in diameter, averaging about the thickness of the finger; the woody fibre is straw-coloured and brittle, breaking with a sharp fracture; it is almost tasteless, having a slightly aromatic and bitter flavour when chewed.

The bark contains whatever medicinal virtues are in the plant. It is of grey colour, slightly ribbed or fluted longitudinally from unequal contraction while drying on the branch; increasing in thickness in proportion to the diameter of the woody stem, in the thicker branches constituting more than half the weight of the whole, in the thinner somewhat less than half; readily separable from the stem by pounding or bruising, when it comes off in clean longitudinal pieces, brittle in the transverse fracture; of a warm, aromatic, camphor and bitter taste, resembling the cascarilla of the old collections. Under the lens it is readily resolvable into three layers: 1st, the inner layer or cambium of reticular woody tissue, having granules of starch and particles of resin imbedded; 2nd, a middle layer of woody fibre and dotted ducts, resinous particles also in this layer; and 3rd, the cuticular or outer layer of cells, of a brownish colour, and containing colouring matter and tannic acid.

The usual methods of filtration from digestion in the usual solvents, as gasolene boiling at 110°, ether, alcohol, carbon disulphide, water, etc., were adopted.

1. Ratio of bark to wood—

Bark	49·72	Mean of these experiments.
Wood	50·28	
	100·	

2. 100 parts of bark yield—

Moisture at 100° C.	8·
Mineral salts (ash)	12·
Vegetable substance	80·
	100·

3. This vegetable matter was separable into the following:—

Fatty matter soluble in ether, and partially in strong alcohol	·7
Yellow resin, soluble in alcohol	2·7
Gum and glucose from starch	·5
Tannin, yellow and brown colouring matters (extractive)	12·6
Cellulose, lignin, etc.	63·5
	80·

No crystalline alkaloid or active principle was separable by the usual methods of proximate analysis. A plan similar to that used for cinchona alkaloids, and also that by precipitation with diacetate of lead, was tried. By distillation no volatile oil or acid was obtained.

Whatever medicinal virtues the plant may possess must reside either in the yellow resin or in the extractive; the former is soluble in alcohol, and the latter in water. In the watery decoction some of the resin is diffused, but the greater portion of the resin is not extracted by the water. The therapeutic position of the plant, judged from analysis, might be among the aromatic bitters.—*Amer. Journ. Pharm.*

ENGLISH CHLOROFORM IN GERMANY.

BY DR. F. VERSMANN.

Many professors of German laboratories and proprietors of chemical works have adopted the valuable plan of communicating to the journals, from time to time, observations and points of practical experiences made in the course of their investigations; and it would be well if this plan was imitated here, as much labour and trouble may often be saved by this liberal exchange of practical information.

This arrangement, like everything good, is, however, not quite unalloyed, for it sometimes happens that statements are published which are of little use, or which, on examination, are found to be incorrect. The last is the case with a communication in a current number of Buchner's 'Repertorium der Chemie,' and as this special incorrectness bears on an English article, it may not be out of place to rectify it. Mr. E. Schering, in his practical communication, asserts that abroad English chloroform, sp. gr. 1485, is, for anæsthetic purposes, preferred to the German (the Prussian Pharmacopœia prescribes a specific gravity of 1500) because of its greater stability.

According to Mr. Schering, the presumption was natural that the English product had been obtained from chloral, and this idea was actually verified by Mr. Hager's investigation, who found it to be chloral chloroform with an addition of ·75 to ·80 per cent. of alcohol; but not a word is said as to the manner in which this result had been arrived at. Mr. Schering refers his readers to his price list of last year, in which he quotes chloral chloroform, and he informs them that he now keeps an article of sp. gr. 1485, identical with the English, or, according to his own words, adulterated with alcohol.

Mr. Hager actually distinguishes the two preparations; he says, the chloral chloroform becomes slightly coloured on addition of strong sulphuric acid, whereas the pure, obtained from hypochlorite of lime and alcohol, remains colourless.

Another difference is said to be, that ordinary chloroform, on being allowed to evaporate on a watch-glass, gives off, with the last few drops, a distinct foreign smell, indicating the presence of other chlorine compounds, which may be the cause of the ready decomposition of the chloroform when exposed to the light, and this is not the case with the product obtained in the new manner.

The manufacture of chloral in quantities and at a reasonable price, is of so recent a date that it is scarcely necessary to recall the fact that seldom, if ever, the supply of any chemical compound responded so readily to the demand, as with the chloral. The price of chloral hydrate was, at the commencement of last year, 112*s.* a pound; before the year was out it had gone down to 12*s.*, and it is now sold at 5*s.* and even less.

Surely at this time when the hydrate commanded such high prices and the manufacture was in its infancy, no English manufacturer would have dreamt of converting chloral into chloroform, and with the present low prices and the high duty on alcohol, he is all but excluded from the market; it is well known that very nearly all chloral hydrate is imported from Germany, and I believe I am correct in stating that only two English firms do manufacture it in quantities.

Mr. Schering's whole argument necessarily falls to the ground, and for the best of reasons, the manufacture as assumed by him would never pay. It would perhaps have been wiser if he had prided himself upon the purity of his product instead of boasting of selling an adulterated article. His tests are of course worthless, because even less than 1 per cent of alcohol will be sufficient to produce slight coloration with sulphuric acid, but it is scarcely necessary to treat the matter as a chemical question.

FLUID EXTRACTS AND THEIR MENSTRUA.

BY EDWARD R. SQUIBB, M.D.

(*Continued from page 46.*)

Diluted alcohol, as at present officinal, consists of equal measures, at 60° F., of alcohol of specific gravity ·835 and distilled water, and has a specific gravity

at 15·6° C. = 60° F. ·94118.
at 25·2° C. = 77° + F. ·93438.

This, when made from alcohol s. g. ·81674 at 15·6° C.,

requires 100	measures of the alcohol	at 15·6° C. to	
112·54	„ „ distilled water	at 15·6° C. or	
100	„ „ „ „	15·6° C.	
require 88·85	„ „ the alcohol	at 15·6° C.	

Made by weight,

100 parts of the alcohol	require	136·86 distilled water,	
or 100 „ distilled water	„	73·06 alcohol.	
100 „ alcohol, s. g. ·835,	„	119·84 distilled water,	
or 100 „ distilled water	„	83·44 alcohol, ·835.	

One pint of this diluted alcohol

at 10·6° C. = 51° F. weighs 446·30 gram. = 6887 grains.
at 30·6° C. = 87° F. „ 439·69 „ = 6785 „

20° C. = 36° F. 6·61 „ = 102 „

Made with alcohol s. g. ·8208 at 15·6° C. = 60° F.,

100 parts alcohol require 135 parts distilled water, and the s. g. of the mixture

at 15·6° C. = 60° F. is ·941849.
at 25° C. = 77° F. is ·935422, or ·000684 for ca. 1° C.

One pint of this mixture

at 10·6° C. = 51° F. weighs 446·50 grm. = 6890 grains.
at 30·6° C. = 87° F. „ 439·75 „ = 6786 „

20° C. = 36° F. 6·75 „ = 104 „

A mixture of three parts, by weight, of stronger alcohol, and one part glycerine, proves to be a very good menstruum for cinchona and rhubarb, and may be found applicable to other drugs.

Made with alcohol of s. g. ·81674 at 15·6° C.
and glycerine „ 1·2523 at 15·6° C.,

the mixture has a specific gravity

at 15·6° C. = 60° F. ·90050.
at 25° C. = 77° F. ·89296, or ·000802 for ca. 1° C.

One pint of this mixture

at 10·6° C. = 51° F. weighs 427·30 gram. = 6594 grains.
at 30·6° C. = 87° F. „ 419·82 „ = 6479 „

20° C. = 36° F. 7·48 „ = 115 „

The other special menstruum thus far studied by the writer is one that has been found well adapted to wild cherry bark, pareira brava and uva ursi. This is a mixture of two parts stronger alcohol, three parts glycerine, and five parts water. By measure this is very nearly two measures each of the alcohol and glycerine, and four of water.

Made from alcohol of s. g. ·81953 at 15·6° C., and glycerine s. g. 1·2523 at 15·6° C., it has a s. g.

at 15·6° C. = 60° F. 1·03833,
at 25° C. = 77° F. 1·03283, or nearly ·0006 for ca. 1° C.

One pint of this mixture

at 10·6° C. = 51° F. weighs 492·03 gram. = 7593 grains.
at 30·6° C. = 87° F. „ 486·97 „ = 7514 „

20° C. = 36° F. 5·06 „ = 79 „

It appears very probable that special menstrua for special drugs can and should be very much multiplied. Indeed, it may be regarded as almost certain that a proper degree of research would show that every drug requires a special menstruum in order to secure the best results. If there be a rule of any general applicability, it is that for drugs which contain definite alkaloids, the menstruum should be as strongly alcoholic as possible a rule which is in opposition to former practice.

It remains now to notice the prominent fluid extracts with which the writer has had most experience, in detail.

FLUID EXTRACT OF ACONITE ROOT.

Not officinal, but should be, and should always bear a red label. The root should be in very fine powder, and the menstruum stronger alcohol. The officinal quantity of powder requires 5 f℥ for moistening, and the moistened powder should be passed through a sieve before packing. A pint of the menstruum at 25° C. = 77° F., weighs about 5907 grains, and a pint of the finished preparation, at the same temperature, should weigh about 6350 grains, giving a difference of about 440 grains, varying somewhat with the quality of the root and the dryness of the powder.

FLUID EXTRACT OF BELLADONNA ROOT.

Not officinal, but should be, as stronger and more uniform than that yielded by the leaf. The two are not necessary, and if the leaf was dropped, the root would soon go into general use. The fluid extract should always bear a red label.

The root should be in very fine powder, and the menstruum stronger alcohol.

FLUID EXTRACT OF BUCHU, OFFICINAL.

The leaf should be green and fresh, the short buchu the best, and be in very fine powder. Many menstrua tried, with various portions of glycerine and water, but none so good as stronger alcohol. About 8 f℥ required to moisten the powder, which should be passed through a sieve before packing. A pint of the menstruum weighs about 5907 grains, and a pint of the finished preparation about 6677 grains, giving a difference of about 770 grains.

FLUID EXTRACT OF CIMICIFUGA, OFFICINAL.

The root being in very fine powder, the officinal plan yields an excellent preparation by repercolation. The process could, however, be much simplified.

FLUID EXTRACT OF CINCHONA, OFFICINAL.

The bark should be in very fine powder, the menstruum one part glycerine and three parts alcohol, and 8 f℥ should be used to moisten the powder before sifting. Many menstrua were tried with this drug, but none seemed to answer so well as the mixture indicated. With it a fluid extract was prepared of which a minim represented about one and a half grains, and this has now stood more than four months without a deposit. Therefore, a preparation of one minim to the grain, or double the present officinal strength, would probably stand indefinitely, and this change of strength is, in the writer's judgment, very desirable. The details of this percolation are given in the tables. In the management of this drug the weak percolates become overloaded with extract from time to time, but the alcohol can be easily recovered from them without much damage, as the glycerine takes care of the alkaloids and bitter principles.

The writer has found no demand for fluid extract of colchicum root, and believes it to be a useless preparation, while that of the seed is so commonly used, and a more uniform preparation.

(*To be continued.*)

THE THEORY OF DISINFECTANTS.*

BY T. P. BLUNT, M.A., F.C.S.

The light which has recently been thrown upon the nature of contagion and infection by the labours of Pasteur and others, the results of which have been ably summarized by the President of the British Association in his late inaugural address at Liverpool, seems to point the way to clearer and more comprehensive views than those commonly entertained at present regarding the operation of the substances known as disinfectants.

These may be divided into two classes:—1. Those which act by the oxidation and total destruction of the virus contained in infected matters, together with the foul gases which usually accompany it, and which are, in fact, nature's danger-signals of its presence. 2. Those substances which do not possess the active chemical properties of the first class, yet are proved by experience to have a similar power of arresting and checking the spread of infection. The latter are, for the most part, the more ancient and popular, having apparently in some cases been suggested by a just but unreasoning instinct. Thus we find that the use of sulphurous acid, as evolved from burning sulphur, dates even from Homeric days; while the burning of pitch and aromatic gums for disinfectant purposes has an origin at least equally remote.

An attempt will be made, in the course of the observations which follow, to bring the operation of the large majority of the latter class under a general law which shall furnish us with an explanation of their true character. This is especially desirable, since it is to be feared that, for want of such an explanation, many good and valuable disinfectants have been condemned by chemists, on theoretical grounds, as mere deodorizers,—not assailing the virus of infected substances, but rather masking their poisonous character by precipitating their offensive gases. An objection to this view at once meets us, in the utter disproportion between the volume of the gases to be fixed and the quantity of salt practically found sufficient for the object required, while it breaks down altogether when applied to such disinfectants as the new "chlor-alum" or chloride of aluminium of Mr. John Gamgee, or the well-known carbolic acid. Before endeavouring to supply a more probable theory, it may be well to remind you that the researches already mentioned have established the fact that contagion and putrefaction, if not actually identical, are processes so closely allied that they require exactly similar conditions; the latter appearing to consist of a kind of disease propagated from particle to particle of a decomposing substance, and ending in its entire destruction. Hence it may be inferred with perfect safety, that any agent which arrests putrefaction is capable also of abolishing the properties of contagion and infection.

This conclusion at once puts into our hands a valuable instrument of research; for while it is difficult, and often impossible, to investigate directly the disinfectant action of a substance, the inquiry being surrounded by innumerable sources of error, the properties of an antiseptic are perfectly well defined and open to the clearest demonstration. Thus, in the case of the two bodies mentioned above, carbolic acid and chloride of aluminium, the antiseptic action of the first is well known, and has long been usefully applied; while that of the latter is maintained in the most positive manner by its introducer, Mr. John Gamgee, who certainly brings forward overwhelming proof of it in his recorded experiments upon meat and fish; and hence, on the grounds given, we are justified in regarding these substances as good and useful disinfectants. It may be stated, in passing, that the deodorizing power which these and other similar bodies possess is probably due to their antiseptic action; the offensive gases of decomposition being sooner lost by diffusion, and their fresh production being entirely suspended.

Let us now proceed to a consideration of the origin of the remarkable properties which we have described. This appears to have been traced with some degree of probability, in the case of carbolic acid, by Dr. Joseph Hirsch, the writer of an article which appeared in the *Chemical News* about the end of February, 1869. He advances the bold and ingenious speculation, that the disinfectant action of that substance depends upon its power of coagulating albumen. He supposes that the acid finds its way into the minute organisms, which propagate disease by diffusion through their investing membrane; that it coagulates the albumen which they, in common with all germinal matter, contain as a necessary constituent; and thus practically destroys their vitality as perfectly as immersion in boiling water terminates that of an egg.

In order to test the accuracy of the view thus enunciated, I selected a substance of which the albumen-coagulating power was well known, and examined it with regard to its antiseptic, and, therefore, disinfectant properties. The substance chosen was nitro-muriatic acid, which has long been in use as a test for albumen in urine. The experiments were conducted as follows.

a. Two samples of fresh healthy urine, passed at the the same time, each measuring about one ounce, were placed side by side. To one of them six drops of strong nitro-muriatic acid were added. In a few days, the unacidified specimen was covered with a thick crust of mould; while that to which the acid had been added was unaltered, except by a slight darkening of colour and deposition of crystals of uric acid.

b. Some fresh meat was pounded into an emulsion with water,—the whole divided into two equal portions of about six drachms each. To one of them six drops of strong nitro-muriatic acid were added, as in the former case. In a day or two, the unacidified sample was quite putrid and offensive; while that to which the acid had been added retained the smell of fresh meat, and continues to do so still, after the lapse of nearly a month.

I now proceeded to test some of the salts commonly used as disinfectants, with respect to their possession of this power of coagulating albumen. The examination was conducted thus. One part of the salt to be tested was dissolved in one thousand parts of distilled water, and the solution was mixed thoroughly with the fresh white of egg. The salts examined were iron-alum, sesquichloride of iron, common alum, chloride of zinc and nitrate of lead. Coagulation followed immediately in every instance. In one or two cases the dilution was carried much further,—one part of the salt to three or four thousand of water. Here, too, coagulation followed in one or two seconds.

It may be remarked, in passing, that the hæmostatic action of the iron-salts is probably to be attributed in great measure to this faculty of coagulating albumen, exercised upon the serum of the blood.

The attempt to obtain similar results from the sul-

* Read before the annual meeting of the Shropshire Scientific Branch of the British Medical Association.

phites entirely failed. They appeared, indeed, to retard coagulation by other reagents. The coagulating power of sulphurous acid was faint and ill defined.

If we review the evidence now before us, we shall find that it stands thus.

We start with two assumptions,—the first justified by recent research, the second borne out by analogy, viz. that infection results from the transference and development of minute germs; and that these germs contain albuminous matter as a necessary constituent, the coagulation of which terminates their existence. Upon these assumptions we frame our major premiss,—that "all coagulators of albumen are disinfectants;" and, having arrived at this result by a process of pure reasoning, we proceed to prove its truth by experiments upon the antiseptic, and so upon the disinfectant, properties of a well-known albumen-coagulator. Having thus established our fundamental proposition, we produce experimental proof of our minor premiss—that "nearly all the substances to which popular experience has assigned the property of arresting the spread of infectious diseases, where that power is at present unexplained, are coagulators of albumen." The conclusion then necessarily follows, that these substances are disinfectants; and thus a vindication of their efficiency is furnished in those cases where it has been called in question by chemists on the ground that no sufficient explanation of their action had been offered.

The above conclusion does not apply to sulphurous acid and the sulphites. In their case, we must probably look for some more remote physiological effect upon germinal existence.

Note on the Use of Hydrochloric Acid as an Antiseptic.

It is probable that hydrochloric acid, which shares the properties attributed to nitrohydrochloric acid in the foregoing remarks, will be found to be a valuable preservative of animal food. A piece of meat, immersed for fifteen minutes in a mixture of one part of the acid to three of water, remained entirely free from putrefactive change after nearly a fortnight, though the action of the acid was not sufficiently powerful to prevent the appearance of a small quantity of mould. The meat was then immersed in a dilute solution of carbonate of soda, and the superficially absorbed acid was thus converted into common salt. This reaction obviously gives hydrochloric acid a great advantage over other antiseptics, which introduce into the food a foreign substance, inimical by its very nature, in most cases, to the process of digestion.—*The British Medical Journal.*

SOLUTIONS OF ALKALOIDS IN MEDICATED WATERS.

In the July number of the *American Journal of Pharmacy*, Professor Maisch mentions a case that had been brought under his notice, in which a prescription ordering sulphate of morphia dissolved in peppermint water, having been dispensed with peppermint water made according to the United States Pharmacopœia, by triturating the oil with carbonate of magnesia and water, it was found that the sides of the bottle, upon its being brought back for a renewal of the prescription, were covered with crystals. The crystals were collected, and, upon examination, proved to be morphia. He calls attention to the fact that the process of the United States Pharmacopœia, above alluded to, yields in all cases a medicated water having an alkaline reaction, which is shown by the reddish-brown colour produced by it in a diluted solution of turmeric. He says, "If chloride of ammonium and ammonia water are added to such a medicated water, any soluble phosphate will, in a short time, produce a dense cloudiness and finally a precipitate. It is unnecessary to enter into the causes of the solubility of magnesia under these circumstances; the fact is a plain one, and the possibility of dangerous effects very obvious. Neutral salts of insoluble (in water) alkaloids may be dissolved in such medicated waters, but the alkaloids will be gradually precipitated in a form in which they cannot be uniformly diffused in the liquid even by agitation; hence the possibility, if the separated alkaloid does not firmly adhere to the vial, that the last dose may contain an excessive amount of a poisonous article; while, in case it should adhere with sufficient firmness, the result might be, at least, disappointment in the effects, if nothing worse, in consequence of insufficient medication." Professor Maisch thinks that this furnishes an additional and strong argument for the preparation of medicated waters by distillation; and that, where waters prepared from volatile oils by the aid of magnesia are used, it is the duty of pharmacists to neutralize or slightly acidulate them when poisonous alkaloids are to be dissolved therein.

FUNDAMENTAL DIFFERENCE BETWEEN THE STRUCTURE OF ALBUMEN AND THAT OF CASEINE.

BY J. ALFRED WANKLYN.

Among the determinations of the quantity of ammonia evolved by the action of alkaline permanganate of potash on organic substances, Chapman, Smith and myself have already published that caseine yields 7·6 per cent of ammonia, and that albumen yields about 10 per cent. We considered, however, that a result of such importance required confirmation; and refraining from drawing the conclusions legitimately following from it, pointed out that in the instance of the caseine taken for our experiment some further guarantee was desirable. Confirmation has been given; caseine having been shown to yield 6·5 per cent. of ammonia—rather less than before, and, consequently, even further removed from albumen than was at first represented.

In ultimate percentage composition albumen and caseine are indistinguishable. In oxidation products they have, up to the present time, been considered as being alike. Only in some small reactional characters, as, for instance, that the one is, and the other is not, precipitable by acetic acid, had they been distinguished. The difference in the yields of ammonia, which we now insist upon, points to deep-seated difference in chemical structure, and shows that albumen and caseine, which are metameric, and possibly, even isomeric with one another, belong to different chemical families.

Inasmuch as the albuminous compounds of young mammals have necessarily been obtained by metamorphoses of the caseine supplied in the milk which they feed upon, the process of assimilation must consist partly in fundamental chemical change, and not merely in morphological changes and superficial chemical alterations.—*Milk Journal.*

PILL-MASSES FOR PROTOSULPHATE OF IRON AND CARBONATE OF POTASH.

In the *American Journal of Pharmacy*, Professor J. M. Maisch, referring to a combination of protosulphate of iron and carbonate of potash sometimes prescribed in the form of pills, and the various methods proposed for overcoming the hygroscopic tendency of the carbonate of potash, speaks with approval of a suggestion made in the *Pharmaceutische Zeitung* to substitute for the iron sulphate an equivalent quantity of the exsiccated salt, and, after triturating it with the potash salt, to beat it with honey into a mass of proper consistence. The slower solubility of the exsiccated salt would necessarily render such pills slower in their effects, but probably not sufficiently so, he thinks, to be objectionable. He reports that he has obtained excellent results by manipulating as follows:—Sulphate of iron, granulated by precipitation of its solution with alcohol, is rubbed together with the carbonate of potash; the mixture becomes soft and changes in colour, in consequence of the formation of carbonate of iron and the liberation of water of crystallization. Powdered tragacanth is now added, and by beating with a few drops of syrup a very good pill-mass is obtained. The proportions may be seen from the following:—

℞ Ferri Sulphat. pur.
Potassæ Carbonat. pur. aa. ʒij
Pulv. Tragacanthæ ʒss
Syrupi Simplic. gtt. v–vj
M. ft. pilul. No. 60.

Sulphate of iron always gives more or less trouble in the formation of pill-masses with the usual excipients. In many cases a little glycerine will probably be found superior to any other, as is the case with the following prescription, which will give a crumby, unsatisfactory mass with syrup, honey and mucilage, but is unobjectionable when glycerine is employed:

℞ Ext. Nucis Vom. gr. x
Ferri Sulphat. gr. xx
Quiniæ Sulphat. ℈ij
Glycerine, gtt. v–vj
M. ft. pilul. No. 20.

It is remarkable what a large amount of the other excipients the above mixture will take up, while five or six drops of glycerine will have a by far better result.

THE PHARMACY BILL.

NORTH BRITISH BRANCH OF THE PHARMACEUTICAL SOCIETY.

At a meeting of the Council of the North British Branch of the Pharmaceutical Society, Mr. Baildon submitted a motion, which was seconded by Mr. Ainslie, that the Council approves generally of the Amended Bill. The motion was carried, one member only dissenting.

PHARMACEUTICAL AND CHEMICAL ASSOCIATION, SHEFFIELD.

The following letter, submitted to this Society by Mr. G. B. Cocking (Vice-President), and unanimously adopted, has been forwarded to Members of Parliament:—

"*Pharmaceutical and Chemical Association Rooms,*
"*Sheffield, July 14th*, 1871.

"To A. B., Esq., M.P.

"Dear Sir,—At a meeting of the Council of the above Association held last evening, it was resolved to solicit your continued opposition to the 'Act to amend the Pharmacy Act, 1868,' as amended by the Right Honourable W. E. Forster, believing that the objections to the principles contained in the said Act, as already petitioned against by the members of this Association, remain as strong as ever.

"Any protection against poisoning, to be complete or satisfactory, must include the dispensers in private surgeries, public hospitals, infirmaries, parish and other dispensaries, as well as those in 'open shops.' Medical prescriptions are dispensed in private surgeries (for other than private patients) in this and other towns, yet in the amended Act they would be exempt from the poison regulations.

"If the public safety requires any precautionary enactment such as that now proposed, it is certainly desirable and just that all persons, without exception, who keep, sell, or dispense poisons should be equally subjected to any penal restrictions that the Government may adopt.

"The amendments proposed by Mr. W. E. Forster cannot be considered either fair and just to pharmacists or satisfactory to the public, unless the following sentences be eliminated therefrom, viz.:—

"1. In notice of motions, page 1939, 2nd amended clause, 4th line, 'Who keep open shop for the,' the clause then reading thus, '*All* persons retailing, dispensing,' etc.

"2. In 3rd amended clause, 1st line, 'Who keeps open shop for the,' the clause then reading thus, '*Every* person retailing, dispensing,' etc.

"3. Page 1940 (schedule), 2nd line, substitute 'all persons' for 'by persons keeping open shop.'

"With these or equivalent alterations the Act might be considered fair and impartial.

"We are, dear Sir, on behalf of the aforesaid Council,
"Yours respectfully,
"J. T. Dobb, *President*.
"Henry W. Maleham, *Sec.*"

LETTER ADDRESSED TO MEMBERS OF PARLIAMENT.

The following is a reprint of a circular posted to Members of Parliament on Saturday last, and referred to by Mr. Sandford in his letter.*

"*15th July*, 1871.

"Sir,—In 1868, when the Pharmacy Bill was before Parliament, the Pharmaceutical Society had to resist, as strongly as possible, the introduction of restrictive clauses which would have seriously fettered chemists in their daily avocations. This could only be done on the plea that legislators, being utterly unacquainted with the details of the business, were not fairly able to make regulations respecting it, and that chemists themselves were the only fit and proper persons to perform that duty. Acknowledging the force of the arguments used on that occasion, Parliament left the details of the regulations to be observed in the sale and keeping of poisons in the hands of the Pharmaceutical Society and the Privy Council conjointly; the former to initiate, the latter to approve. The Council of the Society, with great care and trouble, framed a code of regulations, simple, practicable, sufficiently elastic as they believed to prevent serious inconvenience, and yet highly conducive to the safety of the public; the regulations were, in fact, taken from the systems of precaution practised in the best regulated establishments. The Society, in whom the power was vested, did not support the views of its Council, and refused by its vote to sanction the recommendation of these or of any regulations for the approval of the Privy Council with the view of their being made compulsory. Thus occasion has been given for the introduction of the Pharmacy Bill now before the House of Commons. That Bill, as it came from the House of Lords, was certainly objectionable in some of its provisions. It gave the Privy Council too absolute power, and left untouched many shops kept by medical men and others, who have special exemptions under the Act of 1868. Mr. Forster's amendments of the Bill will remove both these objections; the first by embodying in a schedule the regulations framed by chemists themselves, thereby relinquishing at once the proposed arbitrary power of the Privy Council; the second by making the provisions of the Bill applicable to all persons who sell or dispense poisons in open shops. Medical practitioners, in the ordinary exercise of their profession, would have perfect immunity from the provisions of this Bill, but in an open shop for the sale and dispensing of medicine, a doctor becomes a retail dealer, and in that shop should conform to rules as other retail dealers. Believing that an early settlement of this question will conduce to the welfare of chemists and druggists, as well as to public safety, *we have presumed to point out to you*

* See p. 79.

how completely the objections to the Bill have been removed, and trust you will support it accordingly.

"We have the honour to be, Sir,
"Your obedient servants,

METROPOLITAN CHEMISTS' DEFENCE ASSOCIATION.

At a meeting of the Committee, held at Freemasons' Tavern, July 18th, the following resolutions were unanimously adopted:—

Proposed by Mr. Urwick, seconded by Mr. Vizer—

"That the Chairman be requested to express to W. T. M'Cullagh Torrens, Esq., M.P., the special and sincere thanks of this meeting for his valued services which have resulted in the withdrawal of the Pharmacy Bill."

Proposed by Mr. Greenish, seconded by Mr. Pattison—

"That this meeting desires to express its sense of obligation to Jacob Bright, Esq., M.P., for his cordial assistance in resisting the Pharmacy Bill."

Proposed by Mr. Urwick, seconded by Mr. Hemingway—

"That the Chairman be requested to thank Dr. Brewer, M.P., for the step he has taken in connection with the Pharmacy Bill."

Proposed by Mr. S. C. Betty, seconded by Mr. Bland—

"That this meeting tenders its hearty thanks to all those Members of Parliament through whose influence and services the Pharmacy Bill has been successfully opposed." EDWIN B. VIZER, *Honorary Secretary*.

The Pharmaceutical Journal.

SATURDAY, JULY 22, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PHARMACY BILL.

ALTHOUGH the withdrawal of this Bill was received with general approval in the House of Commons on Monday evening, we cannot avoid expressing regret that it was not then dealt with more definitively than by withdrawal, to which even important measures are subject at this stage of the Session, and more especially under existing circumstances.

We regard it as a misfortune that this question should still be left unsettled, for the letters and other documents we publish to-day in reference to the subject of poison regulations sufficiently show that the result will be a continuance of conflict. Those who are more or less favourable to compulsory regulations are evidently aggregating together, and making use of the example set by the opponents of the Bill. If they continue to do so with anything like the energy and activity manifested by those who have opposed the Bill there is every reason to anticipate that the contest is by no means at an end. We cannot hope to take leave of this Bill by endorsing on its history *requiescat in pace*, and must be content to regard the next few months rather as an armistice, during which it will be the duty of every one connected with British Pharmacy, whether directly or indirectly, to consider well and seriously how much he may be disposed to yield of that which, in the heat of controversy, may have seemed to him indispensable.

We would suggest that the time for discussion is now past and that its continuance might only serve to aggravate an antagonism, which is far from being conducive to the advancement of pharmaceutical interests. It is, we think, rather by individual reflection on all the circumstances bearing on the object of the Bill, and by conference between the several members of the trade, that we should be disposed to hope for such a result being arrived at as would satisfy all, and admit a possibility of united action between the Society and the Privy Council in reference to the very difficult question of poison legislation.

Above all things we would urge upon those who may not hitherto have adopted the precautions recommended by this Society in regard to the storing of poisons, that they should at once remove all ground for complaint on this score, and that according to their particular circumstances, they should give the fullest possible effect to the recommendations issued by the Council.

THE SCOTT CENTENARY.

THE members of this year's Pharmaceutical Conference will find their place of meeting unusually attractive. In addition to the natural beauty of Edinburgh, and its attractions, particularly in early autumn, the SCOTT commemoration will afford them an altogether exceptional opportunity, not only of seeing and listening to some of the most distinguished noblemen, statesmen and *littérateurs* of the land, but also of witnessing a collection of works of art unique in its kind. On Saturday, the 15th inst., was opened, under the auspices of Sir WILLIAM STIRLING MAXWELL, the SCOTT exhibition of pictures and art treasures illustrative of the novels, poems and miscellaneous works of the "great wizard of the North." Probably no one but Sir WILLIAM could have commanded, from the numerous possessors of these treasures, such a hearty and simultaneous response to his appeal for a month's loan of them. The catalogue, just issued, will give some notion of the variety, rarity, and beauty of the collection. A finer or more effective commentary on the works of a man of creative genius was never brought together, except perhaps the DANTE exhibition during the commemoration at Florence in 1865. And if, in addition to their inspection of these art treasures, the members of our Conference attempt a "raid" into the "land of SCOTT," whether on the borders or in the highlands, they will have more than ordinary reason to congratulate themselves on the errand which brought them to Edinburgh in August, 1871.

We learn there is now every prospect of Parliament House being obtained for the reception-room of the British Association. Soirées will be held on the evenings of Friday, August 4, and Tuesday, August 8; on Thursday evening, August 3, there will be a discourse by Professor ABEL, On some recent investigations and applications of explosive agents; and on Monday evening, the 7th, there will be another discourse by Mr. E. R. TYLER, on The relation of primitive to modern civilization.

It is proposed to have excursions on Thursday, the 10th, to the coast of East Lothian and Berwickshire, under the superintendence of Professor GEIKIE; to the top of Ben Ledi, under Professor BALFOUR, and a dredging expedition to the Bass Rock, under Professor WYVILLE THOMSON. Other excursions are proposed to Dalmeny and Hopetown House—to Roslin and Hawthornden—to Abbotsford, Melrose, and Dryburgh, and to the Pentlands, including Messrs. COWAN's paper works.

SCIENCE AT CROSS PURPOSES.

IT has long been alleged as one of the chief advantages of such annual *réunions* as the British Association that they bring together representatives of every department of the same field; that they afford opportunities, not otherwise available, for certain scientific interests to make themselves seen, or heard, or felt, in presence of their neighbours; and that thus there is promoted a mutual respect among the sciences which goes far to neutralize the narrowness and self-sufficiency inseparable from the growing system of division of labour. This advantage has, of late years, been much enhanced by the meeting, within a few days' interval, of other scientific associations besides the British; for example, the Medico-Psychological, the British Medical, the Social Science, to say nothing of our own annual Conference held simultaneously with the British Association. N. M., the *savant*, whatever may be the subject of his special cultivation, has thus been enabled to pass from meeting to meeting to enjoy the discussion of questions in which, though not directly interested, he can yet find the recreation which every fresh subject, scientifically handled, never fails to afford. With the view of facilitating this pleasurable transition from Association to Association, their promoters have generally fixed the scene and date of meeting within a brief space, whether in time or distance, of each other, so as to reduce to a minimum the fatigue and expense of making the "scientific round." This year, however, by a singular and, we hope, accidental, conflict of arrangements, it will be wholly impossible for the visitor at one meeting to be present at another, and for the elementary reason that the same body cannot be in two places at the same time. The British Association meets at Edinburgh on the 2nd prox., and its sittings may be attended along with those of the Pharmaceutical Conference, and, by special arrangement, with the magnificent celebration to be held there on the 9th. So far so good. The attractions to the "grey metropolis of the north" will be stronger this year than they are likely to be for the remainder of the century, and representatives of every scientific, literary or æsthetic interest will meet on a common ground very rarely presented to them. The medical man, whether his speciality be physic or surgery or psychology, is not likely to deny himself the opportunity of enjoying within the first fortnight of August "the feast of reason and the flow of soul" awaiting him in the British Association, the Pharmaceutical Conference and the Scott Centenary. But, by the want of foresight or worse, of the committees of the Medico-Psychological and British Medical Associations, not only members of his own but of other professions can do so only at the sacrifice of attendance at those bodies,—the Medico-Psychological assembling in London, under the presidency of Dr. Maudsley, on the 4th prox., and the British Medical, under the presidency of Mr. Whipple, on the 8th at Plymouth! Surely this is a great and altogether gratuitous *fiasco*. The holding of the British Association at Edinburgh, the Medico-Psychological in London, and the British Medical at Plymouth, either simultaneously or within a few hours of each other, so far from facilitating that transition from one to the other hitherto so agreeable and profitable, will simply lead to comparisons proverbially odious, and to preferences not very flattering to the two malopportune meetings at London and Plymouth.

PETROLEUM TESTING.

In an article on this subject which we published last week, Professor Attfield does good service in distinctly pointing out that in regard to any sample of the hydrocarbon oil, now popularly classified under the name "petroleum," the coincidence of the "flashing-point" with the standard fixed by law is a matter dependent on the circumstances under which the test is applied. This fact has long been well known to those engaged in testing such oil, and it has been equally well known that the result of testing would be above or below the standard, according to the way the test was conducted. It is to this circumstance that the troublesome discrepancies may be referred which have perplexed magistrates and annoyed dealers, and we are glad to see the fact plainly stated. To any one desirous of testing oil fairly, there is no difficulty in obtaining a proper result, and there is no special virtue in any one form of apparatus. All that is necessary is clear definition of the conditions under which the test is to be made, and uniform adherence to them in making the test.

At the meeting recently held in the City it was apparent that there may be still some reason to fear discrepancies in the results of testing with a covered vessel, for a report was produced from three chemists declaring that the average difference between the results obtained with the old test and the new one was less than fifteen degrees, and this was immediately confronted with another report from three other chemists, declaring the difference to be over twenty-five degrees.

It is much to be regretted that the production of such conflicting testimony from scientific men should be possible.

SICK AND WOUNDED.

The Society for the Aid of the Sick and Wounded in War has been vying with the medical profession in doing honour to to the delegation of the "Ambulances de la Presse," charged with the thanks of the French nation for the sympathy and support accorded to it by England during the late struggle and its disastrous sequel. At Greenwich on Saturday, Colonel Loyd Lindsay entertained a brilliant company assembled in honour of Dr. Ricord, Dr. Demarquay, Count Flavigny, and Count Leruier, the representatives of the "Ambulances de la Presse." Count Bernstorff was among the guests, and spoke with a heartiness which must go far to soothe the jeabusy of France, whose mortification, by the way, has found vent in abuse not only of the Prussians for their success, but of the English for their impassiveness. Captain HENRY BRACKENBURY described with much pictorial power the privations encountered by the servants of the "Red Cross," whose achievements, though hardly less dangerous, were by no means so dazzling as those of the belligerents. An interesting letter from Miss NIGHTINGALE, read at the close of the evening, held out encouraging prospects for the efficiency of the International Society in the event of another war on an equal scale. At Willis's Rooms, Sir WILLIAM FERGUSSON presided on Tuesday at a banquet given to the French delegates. Dr. RICORD, who spoke in English, made a really brilliant speech, in eulogy of English medicine, its masters and its dispensers. Dr. DEMARQUAY followed, in French, with felicitous effect; while Dr. GULL brought the evening to a satisfactory termination by proposing the "war correspondents," and in the course of his speech paid a well-deserved tribute to the energy and success displayed in organizing the reception of the deputation by Mr. ERNEST HART.

IMAGINATIVE SCIENCE.

THE forebodings evidently entertained by Professor TYNDALL that some of the propositions laid down in his recent lecture on the above subject would be disputed have proved to be correct, the lecture having received rather severe criticism at the hands of some of our medical contemporaries.

Thus the *British Medical Journal*, while expressing a disposition to welcome such contributions as so able a physicist as Professor TYNDALL can make to medicine in the shape of that exact scientific observation which is the surest basis, points to the circumstance that the Professor's striking experiments have not added anything to our knowledge of the chemical or biological relations of those airborn particles we knew to be ubiquitous even before he illuminated them with the electric beam. Besides this, it is objected that he starts mainly from information derived from chance communications, and then proceeding to reason upon the subject, arrives, by a flight of imagination, at conclusions which are sometimes singularly at variance with facts; as, for instance, when he declares that the most successful workers and profound thinkers of the medical profession are daily growing more and more convinced "that contagious disease generally is of the same "parasitic character as the silkworm disease, called "*pébrine*."

The *Lancet*, also in referring to the note from Mr. ELLIS, quoted by Professor TYNDALL (p. 5), confesses to having entertained a lingering hope that the learned Professor, when he cited and supported such a statement, was amusing himself by an experiment on the credulity of his audience, for such a supposition was less painful than to imagine that one who has climbed the heights of physical philosophy could be so easily misled. It continues:—

"Every one who has ever seen a blister knows that the stretched cuticle, when punctured, does not at once apply itself completely to the surface that it previously covered, but falls more or less in folds, leaving spaces which air must occupy,—carrying with it whatever 'it contains.' Every one who has ever vaccinated knows, also, that in the ordinary methods the entrance of air is prevented by the effusion of blood, which immediately dries into a crust, and hermetically seals the solution of continuity below. Mr. ELLIS's blister must distinctly tend to promote the contact of air with the fluids of the body. His assertion that the occurrence of secondary abscess is by no means uncommon, and his suggestion that his own experience is exceptional in that he has had no such occurrence 'out of hundreds of cases' are alike in direct opposition to facts within the knowledge of every practitioner. If Professor TYNDALL has only such buttresses as these for the doctrines to which he has committed himself, he would do well to lay aside his endeavours to promulgate them.

"From vaccination Professor TYNDALL goes on to speculate upon other questions of medical experience, and to treat of specific contagion generally, in its relation to the derivation of all life from pre-existent life. He here defends himself from an imaginary charge of stepping beyond his *métier*, and does so on the plea that he is not writing a prescription, nor seeking to draw any conclusion from the pulses or tongues of his audience. Such a limitation or description of the sphere of medical duties would be intelligible if it proceeded from the lips of a monthly nurse; but a man of science ought to entertain a different view of the functions of a physician, just as a man of even ordinary discretion might feel some misgiving about his fitness to appreciate the data offered by studies quite foreign to those in which he is accustomed to engage. Before Professor TYNDALL can hold his own in biological investigations, he must find a new balance in which to weigh the value of the statements made to him by those whom he puts forward as authorities.

"Our reference to statements makes it worth while to point out that Professor TYNDALL appears to be desirous of introducing a new nomenclature, which he has not yet made clear by definitions. We have already seen that he advances Mr. ELLIS's 'facts' in order that they may be sifted, and challenged if they be not correct. He refers to the advocates of spontaneous generation as dealing in '*dubious facts* and defective logic.' Now it is really worth while to consider for a moment what must be the state of mind of a lecturer who speaks about 'dubious facts,' and who proposes certain other facts as proper subjects for the operation of sifting, by which, it seems, they may be found not to be 'correct.' We can form no conception whatever of what Professor TYNDALL means either by a correct fact or by a dubious one. The conclusion of the lecture was devoted to a description of an improved respirator, intended to enable its wearer to breathe safely in a burning house; and here Professor TYNDALL, dealing with questions which he has made his own, found himself once more on firm ground, and was able fully to sustain the reputation that at first he had so gratuitously endangered."

ACCIDENTAL POISONING.

IN reference to the case reported and commented on by us the week before last, the *Graphic* has the following remarks, which show that the writer was not only misinformed as to the facts, but is also under very erroneous impressions otherwise:—

"An Islington jury has this week expressed the opinion that chemists and dispensers of medicines generally should be compelled to keep all poisonous packets in paper of a distinct colour reserved expressly for that purpose. The suggestion is a simple one, and the facts which give rise to it certainly warrant a suspicion that there is something wrong in the internal economy of these gentlemen's establishments. It appears from evidence given that it is the custom at the Islington Dispensary to keep powders in a drawer containing sixteen divisions. Every one of those divisions has a label; but the slightest error in assigning the powder to the proper place is, of course, likely to lead to unfortunate consequences. In addition to this it is stated to be the custom at Islington to keep 'kino powders,' which are composed of opium, in the very next compartment to one containing very harmless packets of rhubarb and soda, and so it happened the other day that the apothecary made a little mistake, and the result was that two children of a Mrs. Ford were subsequently found dead in their bed. As the apothecary had clearly no intention to take the lives of Mrs. Ford's children, a verdict of death from accidental causes was agreed upon; but it is certain that if some very simple precautions had been adopted the victims of this accident would have been still alive. There is, we believe, a Society of Chemists and Druggists who are very conspicuous at times in urging upon the Legislature the necessity of forbidding anybody to prepare prescriptions who has not passed an examination in Horace and Virgil; but it would, perhaps, be more to the point if they joined in recommending the trade to make some little distinction between the external appearance of harmless and poisonous powders."

We presume the Pharmaceutical Society is here referred to, but our contemporary does not appear to be aware that the object of the Pharmaceutical Society, in its long-continued efforts to ensure the competence of dispensers, was mainly one conducive to the public interest, or that those efforts—now seconded by law—have been the means of inducing chemists to adopt, more generally than was at one time the case, precautions calculated to prevent the possible substitution of a poisonous drug for a harmless one. In this respect, therefore, his strictures are altogether inappropriate; and as regards the particular case of mistake referred to, he seems to have overlooked the fact that it occurred at a dispensary, and not in a chemist's shop. We hope it would now be very unusual to find a chemist's shop where "kino powders" and packets of rhubarb and soda were kept in such careless proximity that one could be readily mistaken for the other.

Dr. J. Baker Edwards, Ph.D., F.C.S., formerly a member of the Council of the Pharmaceutical Society of Great Britain, has been appointed Professor of Chemistry and Microscopy in the Medical Faculty of Bishop's College University at Montreal. The University has also conferred upon him the degree of D.C.L. *honoris causâ*.

At Brighton a numerous committee has already been formed to make arrangements for the reception of the British Association in 1872. Steps are being taken to secure the attendance of as many foreign *savants* as possible.

MNEMONIC STIMULANT.

A German philosopher has said "ohne Phosphor kein Gedanke" (without phosphorus there can be no thought), and one of his countrymen appears to have taken advantage of the statement, and turned it to practical account. We see the *British Medical Journal* reports that—

"A person named G. M. Raufer puffs and sells for three shillings, under the name of 'lemonade for strengthening the memory,' a fluid mixture of about 30 grammes, containing 15 parts of phosphoric acid, 15 of glycerine and 70 of water. This is sold in Vienna."

We think if there be any reality in the virtues alleged to be possessed by this preparation, that it might indirectly be a source of great relief to Lord Chief Justice Bovill, the Solicitor-General, and all concerned in the case of Tichborne *v.* Lushington; that is to say, provided the claimant could be induced to put himself under a course of it.

The Chemical Section of the British Association will be presided over by Professor Andrews, of Belfast. The Vice-Presidents will be Professors Anderson and Brazier, and the Secretaries, Messrs. J. G. Buchanan, A. Vernon Harcourt, and T. E. Thorpe.

The American Pharmaceutical Association will hold its nineteenth Annual Meeting in the city of St. Louis, Missouri, on Tuesday, the 12th of September next. Arrangements are being made for an extensive display of objects in any way connected with pharmacy, and a special appeal is issued to obtain specimens of crude drugs indigenous to the south and west, so that the materia medica of the great valley of the Mississippi may be efficiently represented.

We are informed in *Nature* that the meeting of the American Association for the Advancement of Science will be commenced at Indianopolis, Indiana, on the 17th of August, under the presidency of Professor Asa Gray.

Professor Attfield's paper on the "Chemical Nomenclature of the Pharmacopœia" is the subject of a review in the *American Journal of Pharmacy*, in which an approval is expressed of the suggestions made in the paper. The reviewer concludes by saying, "Our views coincide in principle with those advanced by Professor Attfield, and we heartily commend them to the consideration of the committee having in charge the revision of the United States' Pharmacopœia."

Transactions of the Pharmaceutical Society.

EXAMINATION IN LONDON.

July 12th, 14th and 19th, 1871.

Seventy-nine candidates were examined,—nineteen Major and sixty Minor; the following passed, and were declared duly qualified for registration:—

MAJOR (as Pharmaceutical Chemists).

- *Davenport, Horace .... London.
- *Iredale, Thomas .... Leeds.
- *Parker, John Samuel .... Peterborough.
- *Bateman, John Montague .... Canterbury.
- Goodwin, Felix .... Newark.
- Wilford, Josiah .... Newport Pagnell.
- Hackett, John Henry .... Lincoln.
- Cole, Walter Benjamin .... Weymouth.
- Fegan, John .... Exeter.
- Stoakes, Benjamin Maidens .. Boston.
- Tomkins, Henry .... Bedford.
- Holmes, Nathaniel Wheatcroft. Grantham.

MINOR (as Chemists and Druggists).

- *Webster, John .... Market Deeping.
- *Ward, John James .... Newark.
- *Kirby, Frederick .... Bridgnorth.
- *Wade, James Henry .... London.
- Shillcock, Arthur .... London.
- Watts, Joseph, jun. .... Attercliffe.
- Heppell, James .... Forest Hill.
- Harrison, William Hopper .. Barnstaple.
- Bryars, William Hudson .... Goole.
- Fortnam, Frederick Henry .. Willenhall.
- Equal.
  - Dunn, Frederick Edwin .... Uttoxeter.
  - Evans, Thomas .... Salford.
- Cowgill, Bryan Horatio .... Manchester.
- Equal.
  - Bradley, John .... Leeds.
  - Bowers, Joseph William .... Olney.
- Ellis, George .... Southport.
- Equal.
  - Banks, Edward .... Salford.
  - Collins, Martin Austin .... Chertsey.
  - Sandy, Frederick William .... Strood.
- Carrington, Edward Green .... Bakewell.
- Equal.
  - Brown, George .... Retford.
  - Pollard, William .... Leeds.
- Emson, William Nicholls .... Dorchester.
- Knowles, William Edward .... Dewsbury.
- Baldwin, Edwin .... Bury St. Edmund's.

The above names are arranged in order of merit.

FIRST, OR PRELIMINARY EXAMINATION.

Two hundred and eighty-seven candidates presented themselves for this Examination on the 3rd July; the following one hundred and ninety-nine passed, and were declared to be duly qualified to be registered as

APPRENTICES OR STUDENTS.

- Royle, John Frederick Sharpe.. Norwich.
- Davies, Walter Lewis .... Stroud.
- Equal.
  - Alderslade, William .... London.
  - Tocher, John .... Aberdeen.
- Crew, William Thomas .... Manchester.
- Emms, William Robert .... Tetbury.
- Hill, Ernest .... Weymouth.
- Equal.
  - Harpham, John .... Newark.
  - Harrington, John S. .... London.
- Newbury, Samuel .... Dorking.
- Lewis, Jenkin .... Droitwich.
- Equal.
  - Davies, Evan .... Birmingham.
  - Hunt, Freeman William .... London.
- Lewis, David .... Merthyr Tydvil.
- Equal.
  - Bullen, George William .... Newark.
  - Lea, Harry .... Ellesmere.
- Gardner, James Richard .... Devonport.
- Equal.
  - Hurran, James .... Leicester.
  - Knight, John Hughes .... Bath.
- Green, William .... Southsea.
- Pass, William John Warhust.. Bury.
- Equal.
  - Atmore, Edward Alfred .... King's Lynn.
  - Broughton, Thomas .... Manchester.
- Equal.
  - Arblaster, Charles .... Birmingham.
  - Cumming, James .... Camberwell.
  - Gulliver, George Ekins .... Holdenby.
  - Williams, John .... Birmingham.
- Equal.
  - Barling, Gilbert Harry .... Manchester.
  - Stone, Edward Ansell .... Oxford.
  - Thomas, Harry .... London.
- Equal.
  - Cobb, Frederic .... Hull.
  - Horsman, Arthur .... Manchester.
- Nicholls, Alfred .... Penzance.
- Equal.
  - Edward, William Wales .... Aberdeen.
  - Lee, Joseph .... Southport.
- Equal.
  - Appleton, Arthur James .... Sheffield.
  - Inglis, James .... London.
  - Wrighton, T. Henry Garland.. Birmingham.
- Equal.
  - Gould, William Robert .... Southsea.
  - Griffiths, Wm. Judge D'Arcy.. Swansea.
  - Widdowson, Reuben .... Nottingham.
- Equal.
  - Stevens, Joseph .... London.
  - Wylde, John .... London.
- Equal.
  - Cassells, Thomas .... Lanark.
  - Davey, John Trimble .... Exeter.
  - Rose, Alfred Wells .... Southwark.
- Equal.
  - Archbold, James John .... Alnwick.
  - Farnsworth, William .... Alfreton.
  - Rundle, Charles .... Plymouth.
  - Smith, Alfred .... Nottinghnm.
- Equal.
  - Chappell, Frederick Abel .... Rochford.
  - Earp, Francis Salsbury .... Battersea.
  - Hatch, James Oliver .... Lancaster.
  - Peck, Edward .... Ely.
- Anderson, George Watson .... Forres.
- Price, John .... Swansea.
- Equal.
  - Appleton, Thomas Alfred .... Brompton.
  - Bond, Alfred .... Manchester.
  - Gardner, William .... Barnard Castle.
  - Moore, John William .... Northampton.
  - Nicholls, Theophilus .... Mitcham.
- Equal.
  - Belton, Richard Headley .... Boston.
  - Cook, Robert .... Great Grimsby.
  - Price, David .... Llandilo.
  - Tearle, Walter .... Ilfracombe.
- Equal.
  - Bartlett, Samuel .... London.
  - Wimble, Frederick .... Birmingham.
  - Woodcock, John Henry .... Manchester.
- Budden, George Alfred .... Wareham.
- Equal.
  - Dear, James Edward .... St. John's Wood.
  - Gwynne, David William .... Swansea.
- Equal.
  - Brown, John Ephraim .... Grantham.
  - M'Farlane, Peter .... London.
- Lester, Henry .... Northampton.
- Equal.
  - Attrie, William .... Southampton.
  - Betts, Samuel .... Leicester.
  - Starkey, George Thomas .... Stratford-on-Avon.
- Equal.
  - Allen, Joseph John William .. Haverstock Hill.
  - Creswell, Alfred Henry .... Clun.
  - Webster, John .... Market Deeping.
- Lawson, John Robert .... South Shields.
- Equal.
  - Anthony, David .... Cardiff.
  - Clark, John .... Dumfries.
  - Fingland, William .... Wavertree.
  - Hudson, Frank .... Clitheroe.
  - King, William Barnham .... Lancaster.
  - Preston, Alfred Charles .... London.
  - Shillcock, George .... Bromley.
  - Tharle, Charles Albert .... Ventnor, I. of Wight.
- Equal.
  - Smith, Alfred Lambert .... Birmingham.
  - Stevenson, Henry Ernest .... Southport.

* Passed with honours.

Equal.
Cheetham, Frank .... Southport.
Culverwell, John Sayer ...... Windsor.
M'Chesney, William James .. Chesterfield.

Gray, Isaac Henry .... Nottingham.

Equal.
Beverley, Robert Henry ...... Nottingham.
Hartridge, James Hills ...... Woodbridge.
Shuffrey, John Clement ...... Hampstead.
Thomas, David .... Llandilo.

Cooper, Albert Henry .... Walmer.

Equal.
Cocker, Justus John .... Over Darwen.
Jones, Thomas M. .... Stafford.
Lathbury, Charles John ...... Nottingham.
Thomas, Llewellyn .... Swansea.

Equal.
Bishop, Richard .... Lynn.
Evans, William Clement ...... Aberdeen.

Equal.
Linley, Frederick William .... Warrington.
Landell, John Tyack .... Wellington.
Smith, Harry Hardisty ...... Leeds.

Equal.
Cliff, James .... Wakefield.
Grace, Charles .... Hammersmith.
Walmsley, Robert .... Clitheroe.

Equal.
Adair, Robert Graham ...... Waltham Abbey.
Otley, John .... Sheffield.

Equal.
Allen, John .... Lancaster.
Beale, James Hawkins Tizard . London.
Colman, Walter John .... Swansea.
Flower, Henry William ...... Derby.
Hobbs, Thomas Henry Hurle .. Wells.
Simpson, William .... Beverley.

Equal.
Hall, J. G. .... Barnard Castle.
Higginson, Alfred .... Manchester.
Taylor, Frederick Gordon .... Bristol.

Equal.
Campbell, Robert Saul ...... Manchester.
Fletcher, Redfern .... Newcastle-on-Tyne.
France, Joseph .... Rotherham.
Hawling, William Henry .... Spilsby.

Equal.
Evans, David .... Windsor.
Hindle, John .... Gorleston.
Skelton, John Hardy .... Gainsborough.

Equal.
Ballard, Frank English ...... Aylesbury.
Gosney, Charles Frederick .... Crewkerne.

Equal.
Askew, Charles .... Jarrow-on-Tyne.
Cryer, Thomas May .... London.
Longbotham, Alonzo .... Ripon.
Smith, Nathan .... Lynn.
Tully, John .... Brighton.
Whitrod, Henry Frederic .... Diss.

Equal.
Ashworth, Amos .... London.
Lloyd, David .... Merthyr Tydvil.
Lund, William Wallace ...... Heywood.

Equal.
Chapman, Josiah Thomas .... Manchester.
Holmes, Alfred John .... Preston.
Smith, Henry Ewbank ...... Barnard Castle.
Wild, John .... Bury.

Heap, Francis .... Tunstall.
Whitgreave, Frederick ...... Kirkham.

Equal.
Ward, Henry Singleton ...... Preston.
Williams, David .... Pembroke Dock.

Mence, William Cookes ...... Barnsley.
Green, Alfred .... Wakefield.

Equal.
Cross, John .... Northampton.
Matthews, Edward .... London.

Equal.
Brown, Leonard Hackford .... Coningsby.
Cott, Francis .... Liverpool.

Jones, Morgan .... Chipping Sodbury.
Pearson, Charles Frederick .. Liverpool.

Equal.
Shemmonds, Adrian .... Uttoxeter.
Sykes, Joseph Spencer ...... Sheffield.

Equal.
Maynard, George .... Moreton-in-Marsh.
Widdowson, Wm. Lawrence .. Nottingham.

Equal.
Barker, Horsley .... Sheffield.
Holdcroft, George .... London.
Hutchinson, Arthur Ellwood .. Boston.
Morcom, Richard Thomas .... Hawarden.
Smith, Frederic Harcourt .... London.
Williams, William .... Aberffrau.
Williams, William Francis .. London.

Bolt, Richard Tanton .... Tavistock.

Equal.
Dufossé, Henri Erneste ...... Gravesend.
Lawson, Edward James ...... Whitstable.

Spencer, Joseph .... West Bromwich.

Equal.
Emslie, J. Alexander Robson .. Aberdeen.
Fieldhouse, Thomas .... Monmouth.
Keen, Nimrod .... Birmingham.
Warriner, Charles William .. Nottingham.

Goundry, John James .... Barnard Castle.

Equal.
Butler, John Norton .... Leicester.
Jerrett, Edward .... Salisbury.
Mutch, John .... Ellon.
Woodcock, Thomas .... Hinckley.

Equal.
Maitland, Pelham Christopher. Launceston.
Morris, Arthur W. .... Ely.
Oakey, Charles .... Preston.

Equal.
Dale, John .... West Bromwich.
Plimmer, William Thomas .... Uttoxeter.
Walker, John .... Witney.

Equal.
Adams, Frederick .... Gravesend.
Greenwood, Joseph .... Preston.
Harper, Lewis .... Aberdeen.
Hesk, Thompson Charis .... Rotherham.
Pask, Thomas Charles .... Liverpool.
Pearson, John Johnson ...... London.
Pidgeon, Joshua David ...... Brighton.
Wilson, Charles Alfred ...... Twigford.

Equal.
Heath, Frederick Devon ...... High Wycombe.
Hoskins, William .... Poole.
Jones, Henry Denson, jun. .. Sheffield.
Sheppard, Richard Reckerby .. Newark.

The following is a list of Towns in which the Examinations were held, with the number of Candidates annexed.

Aberdeen	6	Hereford	1
Abingdon	1	Hertford	1
Aylesbury	1	Hull	11
Banbury	1	Ipswich	1
Barnstaple	2	Kendal	1
Basingstoke	1	King's Lynn	5
Bath	2	Knaresborough	1
Belper	1	Lanark	1
Birkenhead	1	Lancaster	4
Birmingham	8	Leamington	1
Blackburn	5	Leeds	2
Bolton	1	Lewes	1
Boston	3	Liverpool	6
Bradford	1	London	50
Brighton	4	Louth	1
Bristol	1	Ludlow	1

Tavistock	1	Yarmouth	1
Taunton	2		

Proceedings of Scientific Societies.

SOCIETY OF BIBLICAL ARCHÆOLOGY.

At the Meeting of this Society, on July 4th, 1871, Samuel Birch, Esq., LL.D., F.S.A., etc., in the chair, the Rev. F. K. Cheyne, of Balliol College, Oxford, was duly elected a member of the Society.

Mr. B. T. Lowne, M.R.C.S., F.R.M.S., read a paper on the flora of Palestine. He considered that it comprised eight distinct elements—four, the dominant existing floras of Southern Europe, Russian Asia, North Africa, and that of Arabia and north-western India. Each of these floras were stated to occupy a distinct region of the country. Interspersed with these are found numerous examples of plants belonging to Palearctic Europe, constituting its fifth element. The Arctic flora of Hermon and Lebanon constitutes the sixth. Mr. Lowne thought further, that the cedars of the Lebanon moraines and the papyrus of the Jordan lakes were the remnants of two ancient and almost extinct floras, belonging to two distant geological periods.

Mr. James Collins (Curator of the Pharmaceutical Society's Museum) made some remarks upon the gums, perfumes and resins mentioned in the Bible, particularly pointing out the fact, that few of them were indigenous to Palestine, and that even now very few of them can be accurately identified. In the course of his observations Mr. Collins detailed the characteristic differences between the true and false lignaloe wood, and also made a few remarks on ladanum, myrrh, balm of Gilead, frankincense, etc., particularly adverting to the researches of Dr. Birdwood and others, in identifying the frankincense of the ancients with our olibanum. In concluding, Mr. Collins was requested to treat the subject of the gums of the Bible at still greater length on another occasion.

Mr. Lowne and Mr. Collins brought for exhibition a large number of mounted specimens, and a complete collection of gums, perfumes, etc., to illustrate their respective papers. Messrs. Veitch and Co., of Chelsea, had also sent some pots of Palestine flowers which were, by a most unfortunate accident, returned before the meeting.

Some discussion followed the reading of these papers in which Dr. Birch, J. Bonomi, W. R. A. Boyle, Dr. Cull, W. R. Cooper, J. Collins, S. M. Drach, Dr. Hewlett, B. T. Lowne, G. Smith, and Rev. G. Small took part.

A vote of thanks was heartily accorded to Messrs. Lowne and Collins for their very interesting contributions, and also to Messrs. Veitch for their kind co-operation.

The Society was then adjourned to the first Tuesday in November.

ROYAL BAVARIAN ACADEMY OF SCIENCE.

BARON LIEBIG'S ADDRESS AT THE ANNIVERSARY.

The anniversary of the Royal Bavarian Academy of Science was celebrated at Munich, on March 28th, and was opened by Professor Liebig, as President, with the following address:—

We celebrate to-day the one hundred and twelfth anniversary of our academy. Great historic events have taken place since last year's festival; a new Germany has arisen; the dreams of our youth have become reality, and Germany has ceased to be a mere geographical expression. The English people have nicknamed Germany the Fatherland; but this byeword has now assumed, in their mind, a respectable meaning, giving rise to serious reflection, for it is so unexpectedly great that it cannot yet be quite comprehended. In trying to define the true causes of success of our German armies, we shall discover them to be the very same as those which have shaped our progress in medicine and agriculture.

Eminent physicians and advanced agriculturists have been known at all times, and renowned military leaders in like manner; for centuries the fixed idea has therefore prevailed that in the so-called practical avocations practice and experience were all-sufficient, and that theory was not to be depended upon; and why? simply because true theory was not known.

Practical knowledge and aptness are indispensable in following agriculture, and not less so in medicine; but we are now aware that absolutely certain results depend upon the knowledge of causes and intimate acquaintance with all the active principles by which phenomena are influenced; we know that this knowledge is real theory, and that genuine practice is the art of bringing these principles into play at the proper time and of assisting in their reactions. The old practice, based upon uncertain rules, gave way to scientific practice, which is founded on unalterable truths,—the happy inspirations of a genius who grasped a certain law without being able to account for its causes, are resolved into principles and can be worked out and applied by others. The exclusive property of the genius which constituted his superiority, could, by scientific application, be owned by all.

The foundation of the German empire and the German victories steadily following one another have the closest connection with those military events which, sixty-six years ago, overthrew and shattered into fragments the State of Frederick the Great,—a State antiquated and ossified in red-tapeism. One way only existed to heal the wounds of the State and to impart fresh vigour, and this way Prussia followed to the salvation of Germany; by the foundation of the University at Berlin in 1810, the year of the death of the high-minded Queen Louisa, the road had become visible and had been sketched out; the inexhaustible vigour of the mind succeeded where the limited and worn-out material forces were wanting.

German science was destined to become the source of a new and youthfully fresh political life.

Thus we observe the Prussian people labour perseveringly to acquire that power which science alone can give, and all have witnessed the result to which this long and stern struggle has led. The incidents of a war, such as a siege or a defeat, are owing to causes which may be traced as clearly as those of natural phenomena; and the real secret of the superiority of Prussian strategies consists in the study of military sciences upon the basis of exact methods of natural sciences, and in the thorough investigation of, and acquaintance with, the principles ensuring success or defeat.

Among the branches of instruction at the military academy at Berlin, those natural sciences are most carefully studied which may be utilized for warfare, and the discoveries of the last half-century have been made available for military purposes. And just as the philosopher, in order to solve a problem in exact sciences, must commence with the small, apparently trifling subjects, before he understands and masters the greater one, so we Germans had to pass through a long course of schooling and training, while other so-called eminently practical nations named us dreamers; but it was science which, in 1866 as well as in 1870–71, defeated unsound practice; knowledge that imparted strength and stability to force, and created in our adversaries a fear akin to horror of the German system of spies.

Our colleague Professor von Giesebrecht, in his address as rector of the university, has dwelt upon the part which the German universities had in fostering the national idea of unity among the German races; he showed how the national feeling, long a glowing spark, kept alive in legends, and then roused and reared by German poets, at last ripened at the centres of German science.

We are proud that our king was the first German prince to give expression to the national idea of a German empire, and this deed will remain a brilliant monument for him in history.

It may not be out of place to state publicly, on behalf of our academy, that a hatred of races between the German and Latin nations does not and cannot exist. We look upon the heavy misery which Germany has suffered in former times from the French as upon an illness, the pains of which are soon forgotten on recovery.

The peculiar disposition of the German, his knowledge of languages, his reading of foreign characters, the culture of his mind, render him just to other nations, often to the extreme of being unjust to himself; and thus we do not forget how much we owe the great French philosophers, mathematicians and workers in natural sciences, who have been in many branches our teachers and our prototypes.

Forty years ago, when I went to Paris to study chemistry, accident drew Alexander von Humboldt's attention upon me, and a recommending word of his induced Gay-Lussac, one of the greatest chemists and physicists of his time, to propose to me, a youth of twenty, to continue and to complete, under his assistance, an investigation of mine; he placed me in his private laboratory as pupil and assistant; the whole course of my life was thereby decided.

Never shall I forget the kindness with which Arago, Dulong and Thénard met the German student; and how many of my German compatriots might I name who, like myself, thankfully recollect the active assistance in the pursuit of their scientific studies, given to them by French *savants!* Warm sympathy for everything great and noble, and disinterested hospitality are among the finest traits of the French character; they will revive and become active again on the neutral ground of science on which the best minds of both nations must meet in the pursuit of the high common object, and thus the indissoluble fraternization, on scientific ground, will gradually assist in softening down the bitterness which animates the French national feeling towards Germany, the consequence of a war forced upon us.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Pharmacy Act (1868) Amendment Bill.—*July* 13.—Petitions against this Bill were presented from—

Cambridge, by Mr. W. M. Torrens.

Chatham and Brompton, by Mr. Otway.

July 17.—Petitions against the Bill were presented from—

Hastings and St. Leonard's, by Mr. Brassey.

Wath-on-Dearne, Mexborough, etc., by Mr. H. F. Beaumont.

July 17th, 1871.

The Pharmacy Bill.

Mr. Gladstone in the course of remarks on the business of the House said,—There is the Pharmacy Bill, which is in charge of my Right Honourable friend the Vice-President of the Council, but it cannot be expected to pass without a great deal of discussion, and therefore we think it desirable to withdraw it.

The Bill was afterwards withdrawn.

Child Poisoned with "Soothing Cordial."

On Thursday afternoon, July 13, a child named Mary Wood, aged one year and nine months, residing with its parents on Silkstone Common, died under the following circumstances. It appears that about half-past six on the morning of the above day the deceased took from a chair by its mother's bedside a bottle containing soothing cordial, supplied by an unqualified practitioner at Thurlstone, and drank off a considerable portion of its contents. Some time afterwards, the symptoms which usually follow the taking of narcotic poison began to manifest themselves, and these getting more and more aggravated, Mr. C. O. Rowley, surgeon, was called in soon after midday. He at once pronounced the child to be suffering from the effects of poison. The usual counteracting remedies were adopted, but without effect, death taking place at about half-past four. The facts have been communicated to the coroner, who will hold an inquest.

Poisoning by Oil of Vitriol.

On Tuesday last the child of a puddler, living near West Hartlepool, died from the effects of oil of vitriol administered to it by its mother. Upon his return from work the man was met by his wife, who told him she had poisoned one of the children. A medical man was immediately sent for, who found that the little boy, aged about eight months, had been dead about two hours, evidently from poisoning by oil of vitriol, the tongue being partially consumed, and the lips, throat, and chest dreadfully burnt, as also were his hands, which appeared to have been stretched out to push away the burning draught. It appears that in an outhouse, to which the husband and wife alone had access, the former kept a quantity of chemicals for use in experiments connected with his trade, and that a 2 oz. bottle of oil of vitriol missing therefrom was found in the house by the police, near the bed of the murdered child. The woman replied, on being charged at the police station, that she had done it.

Review.

Companion to the last Edition of the British Pharmacopœia; with Practical Hints on Prescribing. By Peter Squire, F.L.S., Chemist on the establishment of the Queen; Chemist in Ordinary to the Prince of Wales; late President of the Pharmaceutical Society; Member of the British Pharmacopœia Committee. Eighth Edition. London. J. and A. Churchill.

Squire's useful and popular 'Companion' is already well and favourably known to our readers. This edition, the eighth, contains, according to the preface, "the new medicines that have been introduced since the publication of the *seventh* edition, and much additional practical information for the prescriber and dispenser."

The new medicines noticed are:—

Chloroformum aconiti, made with the root of the same strength, and by the same process as the officinal liniment of aconite, recommended for the relief of neuralgia by external application on spongio-piline.

The carbolic acid plaster, of the University College Hospital Pharmacopœia.

Chlor-Alum.

Apomorphia, the discoverers' names not mentioned.

Ferri chloroxydi liquor.

Ferri hypophosphitis syrupus.

Chloral hydrate.

Malate of iron wine.

Mustard leaves.

The additional practical information comprises mainly the strength of the solutions for hypodermic injection of carbolic acid, tincture of aconite, sulphate of atropia, acetate and bimeconate of morphia, corrosive sublimate and chloral: a tabular classification of mineral waters, and an amplification of the index, which will be highly appreciated by busy pharmacists and practitioners of medicine.

From a purely literary point of view, we feel it our duty to condemn the unnecessary amount of puffing scattered broadcast throughout this and all previous editions of an otherwise valuable book. In his preface the author tells us he has "omitted many remarks that are no longer necessary;" may we venture to hope that much of that fulsome praise of his own articles, which disfigures the work, and is unworthy of the Queen's chemist, will be omitted in the next edition, or transferred to its appropriate place, the advertisement pages at the end of the book?

The following extracts on the *new* medicines introduced into this edition, fairly illustrate the excellences and shortcomings of our author's style. The italics are ours:—

"Chloral, Hydrate of.—$C_4HCl_3O_2 + 2Aq$.

"A white opaque mass, having a pungent odour, resembling that of a ripe melon.

"*The author is indebted to his son William Stevens Squire, Ph.D. (who, he believes, is the only maker of this preparation in England), for the following outline of the process:—*

"Pass dry chlorine gas, for several days, through absolute alcohol, sp. g. ·795, until it becomes a thick viscid liquid of sp. g. 1·570.

"At the beginning of the operation, the alcohol is well cooled to prevent inflammation and explosion; but towards the end of the operation the alcohol is heated nearly to the boiling-point. The resulting liquid, which after a day or two solidifies to a mass of crude hydrate of chloral, is agitated well with four times its bulk of concentrated sulphuric acid, and the anhydrous chloral which floats on the surface is separated and purified by fractional distillation. The purified anhydrous chloral is placed in a still, mixed with 11 per cent. of water, and distilled over chalk to remove any hydrochloric acid that may be present, the resulting solid distillate is then fused and poured out into shallow vessels to cast into cakes.

"The action of chlorine on alcohol is very irregular, depending upon the temperature and other circumstances, and the crude product obtained is consequently very variable in composition, requiring some modification of the above process, and frequently special methods of purification. It appears that the purest product is obtained by crystallizing the hydrate of chloral once or twice from purified bisulphide of carbon.

"Solubility: 3 in 1 of water and measures only $2\frac{1}{2}$; in glycerine 1 in 1.

"*Test.*—From 100 grains dissolved in $\frac{1}{2}$ oz. of water and well shaken with 1 oz. of liquor potassæ, after being allowed to stand several hours, at least 46 grain-measures of chloroform will separate.

"*Medicinal Properties.*—An excellent hypnotic, producing sound and placid sleep; suitable for hypochondriacal affections, chorea, nervous disturbances, and restlessness, where opium and Indian hemp disagree. Good also in asthma, whooping cough, scarlet fever, diminishes the temperature of the body, has been found useful in idiopathic tetanus, in doses 30 to 60 grains (*Lancet*, Dec. 31, 1870); also for cancer, 20 to 30 gr. doses (*Lancet*, May 14, and June 4, 1870); 10 grs. three times a day (*Medical Times*, Dec. 31, 1870).

"Dr. Tuke, after trying it on several maniacal patients with good results, reports, "Its advantages over other hypnotics are as follows: that it is more uniform in its action and its effects more lasting, it has no depressing influence, it does not constipate nor produce nausea."

"*Dose.*—From 10 to 60 grs.

"An admirable calming draught is made with 15 grs. hydrate of chloral *and 5 minims of solution of bimeconate of morphia.* Dr. Liebreich employs 7 grains, in solution, for subcutaneous injection.

"Effects from an over-dose or repeated over-doses, are cramp in the legs, swimming in the head, flushed face, closed eyes, with injected conjectiva, and in some cases death."

Chlor-Alum.

"An impure solution of chloride of aluminium, sp. g. 1·150. Contains, in a pint, 1500 grs. of the chloride = 75 grains in the ounce. Introduced as a disinfectant and antiseptic by Professor Gamgee. Should be diluted with four times its volume of water for antiseptic use, but may be used stronger for a gargle.

Liquor Ferri Chloroxydi.

"Intensely blood-red colour, same strength as tinct. ferri perchloridi and liquor ferri perchloridi.

"This preparation was made at the suggestion of Mr. Spencer Wells, who had noticed the paper by M. Jeannel, of Bordeaux, describing a yellow and red peroxide of iron, the latter being soluble in very dilute hydrochloric acid.

"Mr. Spencer Wells has found that he can give this preparation to patients who cannot take the tincture of steel; he has also used it as a styptic at operations."

This is the sum total of the information vouchsafed of one of the *new* preparations, perhaps the *newest.* An addendum of the price per pound is only needed to render the information more readily available to pharmaceutists in general.

As the author has published a substitute for chlorodyne, that those who object to prescribe proprietary medicines may be able to order a compound under the above name, with a knowledge of its composition, we trust some competent pharmacist will do us a similar favour in regard to liquor ferri chloroxydi.

Amongst omissions we note the absence of chloroform water, a pleasant vehicle for a large class of nauseous drugs, and too long overlooked; gaseous and liquid nitrous oxide, extensively used as an anesthetic in dental and some minor surgical operations; syrupy phosphoric acid; the so-called hypochloride of sulphur, and its simple and compound ointment. The formula for the well-known compound syrup of the phosphates, published by Professor Parrish in his 'Practical Pharmacy,' is also omitted.

The practical remarks on most of the preparations are beyond praise. We should like to see this part of the work thoroughly revised with each new edition, and the most recent improvements or suggested improvements added. That this has not been the case hitherto is shown by the comments we find under fluid extract of ergot, where we are still told to use a large quantity of expensive ether, which Umney has shown, as the result of some experiments on the large scale, to be useless, and we believe the editor of the Pharmacopœia holds a similar view. We know as a fact that some manufacturers make it without the ether, and that prescribers do not notice any difference in the activity of the preparation.

Again, under cherry-laurel water, the same chemist, and others before him, have pointed out the variability in the amount of prussic acid present in different commercial specimens, depending upon the time of year when the leaves are gathered, and the *modus operandi* of distillation; surely worthy of notice in connection with the dose, and important also as a caution to prescribers.

Notwithstanding these omissions and the blemishes which we have noticed, this book does contain an immense amount of practical and valuable information, such as could only be written by a master of the craft, and for which every member of the trade ought to be thankful.

We congratulate the author on the completion of the edition, begun and ended after he had passed the age of threescore years and ten: and to every chemist and druggist who wishes to keep pace with the times (and who does not?), we cordially recommend it.

BOOK RECEIVED.

FOURTEENTH REPORT OF THE COMMISSIONERS OF HER MAJESTY'S INLAND REVENUE ON THE INLAND REVENUE for the Years ended 31st March, 1870 and 1871.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[274.]—SYR. VIOLÆ.—Having repeatedly made this syrup according to the several published formulæ, without getting it of that intense blue the wholesale maker does, I shall be glad if some of your correspondents will give a little information on the subject. One maker tells me violet flowers are 8*s*. per lb. Are there two kinds? because I have never known them higher than 4*s*.—H. E. GODFREY, 45, *Curzon Street*.

[275.]—GOLD INK FOR ORNAMENTAL WRITING.—*B. T. A.* will feel obliged for a good formula.

[263.]—DISPENSING PRICES.—There being forty doses, sufficient for fourteen days, the price should be that of a 20-oz. mixture. I had to dispense ½ oz. liquor arsenicalis a few days ago, 3 drops for a dose. I put a poison label upon the bottle, which resulted in my having to explain its meaning to the patient, who requested to "dilute it, as he didn't want a case of accidental poisoning in his house."—H. E. GODFREY.

[*** Our correspondent should be aware that he was not compelled to put on a poison label in dispensing medicine of a poisonous nature. The course adopted might be regarded as a *ruse* to substitute a mixture for drops.—ED. PHARM. JOURN.]

[266.]—SYRUPUS QUINÆ ET MORPHIÆ BROMIDI.—(Dr. B. W. Richardson's):

Bromide of Quinine, 1 grain.
Bromide of Morphia, ⅛ grain.
Simple Syrup, 1 drachm.

ARTHUR WM. POSTANS.

[271.]—DISPENSING.—*A. B. C.* will find by first mixing the yolk of eggs with the water he will get the desired result.—THOMAS W. ROMANS.

[273.]—PODOPHYLLUM PILLS.—In reply to the inquiry of your correspondent *A. P. S.* (No. 273) in yesterday's number of the Journal, I beg to hand the accompanying formula for podophyllum pills, which I have found to answer well:—

℞ Pulv. Myrrhæ ℈ij
Sapo. Castil. ʒiss
Ext. Hyoscyami ℈iiss
Podophyllin Res. gr. xij.

Misce et divide in pilulas xlviij. Each pill contains ¼ gr. podophyllum.—THOS. BREWIS.

A. P. S. asks for a formula. The following is a very common one:—

Resin of Podophyllin, ¼ gr.
Extract of Henbane, 2 grs.

To make one pill. One or two a dose.

ARTHUR WM. POSTANS.

I find the following recipe makes very good podophyllum pills:—

Resin of Podophyllum, ¼ grain.
Comp. Pil. of Rhubarb, 2 grains (ij).
Extract of Henbane, 1 grain.

Mix. Make one pill.—T. P. B.

Your correspondent *A. P. S.* may find either of the following formulæ of use to him.—"A. AND B."

No. 1. ℞ Podophyll. Resin gr. iij
Ext. Hyoscyami,
" Coloc. Comp., ana gr. xxiv.
M. et divid. in pil. xii.

No. 2. ℞ Podophyll. Resin gr. vj
Ferri Sulph. Sicc.,
Ext. Hyoscyami, ana gr. xxiv.
M. et divid. in pil. xij.

CARBOLIC CERATE.—The following formula for this preparation is supplied to the *American Journal of Pharmacy* by Mr. Charles A. Bœhme, of Michigan:—

℞ Adipis ℥x
Ceræ Albæ ℥v
Terebinth. Can. ℥j
Acid. Carbolic. ℥j.

Melt the lard and wax together, add the fir balsam, and, when it begins to cool, stir in the carbolic acid.

The addition of fir balsam to this preparation corrects the disagreeable odour of the acid, and renders it slightly adhesive, which is quite desirable when the compound is used as a dressing for burns, old sores, etc.

SODA MINT.—Mr. Henry A. Borell writes to the *American Journal of Pharmacy* that "Soda Mint," much employed as an antacid and carminative for *over-fed* infants and dyspeptics, was originally a favourite prescription of Dr. George Norris, of Philadelphia. His formula was the following:—

℞ Sodæ Bicarb. ℥ss
Spt. Ammon. Aromat. ʒj
Aquæ Menthæ Piperitæ Oj.

M. Dose, from a dessertspoonful or a tablespoonful for adults; from half to one teaspoonful for infants.

TREATMENT OF POISONING BY CARBOLIC ACID.—Mr. Charles Roberts, in a recent communication to the *British Medical Journal*, expresses the opinion that the administration of a mixture of olive oil and castor oil, which has been recommended in cases of poisoning by carbolic acid, with the object of diluting and carrying off the acid by the bowels, is of doubtful benefit, as it causes the acid to pass over the fat-absorbing surfaces of the small intestines. He considers it probable that, as carbolic acid is little soluble in water, the speediest and most effectual way of removing it mechanically from the stomach would be to administer large quantities of warm water or mustard and water. As it is very soluble in glycerine, that substance, with water and sulphate of zinc, might be employed after the bulk of the poison has been removed by the former plan. As to the chemical neutralization of the acid, its affinity for albuminous compounds would point to eggs and finely-powdered raw meat as likely to be of service. If eggs were used, they should be very much diluted by being whipped up with milk or cold water. Milk is not coagulated by carbolic acid, and therefore would not act as a neutralizer, but it would be a more suitable application than oil to the injured mucous membrane.

The following journals have been received:—The 'British Medical Journal,' July 15; the 'Medical Times and Gazette,' July 15; the 'Lancet,' July 15; the 'Medical Press and Circular,' July 19; 'Nature,' July 12; the 'Chemical News,' July 15; 'Gardeners' Chronicle,' July 15; the 'Journal of the Society of Arts,' July 15; the 'Grocer,' July 15; 'Produce Markets Review,' July 15; the 'English Mechanic,' July 14; the 'American Journal of Pharmacy' for July; the 'New York Druggists' Circular' for July.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Metropolitan Chemists' Defence Association.

"The Bill intituled an Act to amend the Pharmacy Act, 1868," is now numbered with the things of the past, and for a considerable time will probably cease to cause excitement and contention in the pharmaceutical world; but as is often the case, warfare makes friends and cements into closer union those who have hitherto known one another by repute alone, so has the battle just fought, in resisting the attempts ruthlessly to fetter the members of our trade, been eminently conducive to the same happy result.

That "union is strength" has again been amply exemplified, and whatever may be the taunts and sneers of our opponents, "that the Bill has been massacred in company with many other innocents, and is only deferred for a more stringent and objectionable form of legislation on a future day," the fact remains beyond dispute—and facts are stubborn things—that, thanks to the efforts of our own and kindred associations, the Government has been compelled, in the first place, so materially to alter the Bill as virtually to constitute it a new Bill, which the House refused to read, even *pro formâ*, without time being given for reconsideration, and subsequently, through our continued resistance to its imposition, entirely to abandon.

"Sufficient to the day is the evil thereof;" a danger met us in our usually quiet course of life, it was faced manfully and has been defeated effectually. What has been done may yet be done again, and instead of fainting at the prospects of a phantom, we will look back with thankfulness and forward with courage and confidence; not desiring to *court* fresh encounters, but prepared, should the emergency arise, to meet it with the same determination as heretofore.

Congratulating our friends upon the result of their co-operation and support,

I am, Sir, faithfully yours,

Edwin B. Vizer.

63, Lupus Street, Belgravia South,
July 18th, 1871.

The Pharmacy Bill.

Sir,—Although the Pharmacy Bill was withdrawn, with many others, on Monday night, from the present session, because, as Mr. Gladstone remarked, it could not be passed without discussion, I think it right to send the accompanying letter,* which was posted to members of Parliament on Saturday last, in order that you may insert it in the next issue of the Journal. Several gentlemen whose names did not appear on the list sent me their approval, but too late to be recorded when the letter was sent out.

47, Piccadilly, London, George W. Sandford.
July 19th, 1871.

Sir,—Mr. Gladstone stated in the House of Commons on Monday last that the Pharmacy Bill was withdrawn. For the present year, therefore, the danger of being placed under any compulsory regulation is averted. It will be well for every member of the Society carefully and dispassionately to weigh over the events of the past few weeks.

It has been asserted that when the Pharmacy Act, 1868, was passing through the House of Commons, "a tacit understanding" was come to between Dr. Simon and Mr. Sandford that he (Mr. S.) would require all the registered pharmaceutical chemists and chemists and druggists to conform to certain compulsory regulations for the storing of poisons.

If such was the case, and certainly the course of action taken by Mr. Sandford, and so zealously pursued, seems to verify the statement, it must be apparent that Dr. Simon, as the medical officer of the Privy Council, asked of Mr. Sandford a promise, the nature and magnitude of which had evidently not struck the learned Doctor, and when Mr. Sandford assented to the promise it was apparently without due thought and consideration.

If this is a correct interpretation of the facts, it is obvious, in endeavouring to persuade the Society to carry out his promise, Mr. Sandford has only been actuated by honourable motives. The number of petitions presented to the House of Commons against the Bill must have satisfied Mr. Sandford that he has misinterpreted the feeling of the trade, and having that fact forced upon him, we can hardly suppose that he will revive the question at any future time.

The far-seeing policy of the Executive Committee of the Defence Association, through whose untiring energy, perseverance and management the withdrawal of the Bill is in a great measure due, cannot be too highly commended, and if next year it is necessary to defend our rights, I hope the same zealous committee will have charge of our interests.

Edwin Yewdall.

Sir,—For the present the attempted tyrannical interference with our business has been defeated. It is not to be supposed, however, that the question is settled. This is only one amongst many other attempts of the same character for the last forty years, and the strong (unprovoked) hostility which a small section of the medical profession entertain towards us is seen in one or two of their journals. This unhappy feeling can only be traced to that desire too commonly manifested,—the natural desire of one man to tyrannize over and oppress another. Once let the chemists submit to this kind of interference, and they will have to submit to it to the bitter end, and will probably be glad to throw up their pharmaceutical privileges altogether. It is not, however, to be supposed that the medical profession generally entertain these sentiments towards us. We know that thousands of them do not; and now that the Privy Council and the Government have seen that we shall not quietly submit to be blotted out of the political world, it is not unlikely they may be more disposed to deal with us as with any other class of men deserving of some reasonable consideration in the land, and that a timely effort on the part of the new Council may succeed in some satisfactory arrangement being effected. Our greatest danger is from those amongst ourselves who seem to invite control and interference from without, and those juniors in the trade who have stepped a little too far out of their position to dictate to the whole body of chemists.

Oxton, July 19th, 1871. Joseph Ball.

Seeing *versus* Feeling and Hearing.

Sir,—An ingenious correspondent in last week's Journal suggested the attachment of a bell to all bottles containing active poisons; may I be allowed to further suggest that instead of one bell, there be connected with the bottle several bells, to ring muffled peals during the time a bottle is being used by the dispenser? Another excellent plan for attracting the dispenser's attention to the deadly nature of the preparations he is handling, would be to have musical boxes connected with the bottles, so that upon removal of a stopper the box would tinkle out the 'Dead March in Saul' in all its awful solemnity. If this plan failed to collect a dispenser's wandering thoughts, I am sure no other would succeed. Putting aside all joking on so important a subject, however, is it not humiliating that we should each week publicly admit an inability to dispense correctly, without being surrounded with such extraordinary safeguards (?) as sandpaper-covered bottles, ingeniously locked stoppers, bottles of inartistic shape, covered with spikes of glass, or with balls attached to them, and dozens of other such childlike toys? Are our eyes less trustworthy than formerly, that we are compelled to substitute the sense of feeling for that of seeing? Of what use is our pharmaceutical training if we require the aid of machinery to remind us which are poisonous and which harmless drugs?

But, although I hold all these fanciful inventions in abhorrence, I am an advocate for arrangement and precaution. By all means separate the poisons from the less dangerous drugs, and place them in a cupboard by themselves. Avoid having two preparations similar in appearance side by side, and carefully extra-label the stronger tinctures, such as hyoscyamus, conium, digitalis, etc., with such labels as those published by Mr. Silverlock, printed on red paper.

In conclusion, may I express a hope that the literary

* See p. 67.

attainments of your numerous correspondents on the poison question will soon be turned to account in the publication of interesting facts respecting experimental and practical pharmacy? A perusal of the pages of the PHARMACEUTICAL JOURNAL for the last twelve months leads me to the opinion, that for most matters of interest in connection with our trade we are indebted to American sources.

Leominster, July 18th, 1871. M. J. ELLWOOD.

POISON BOTTLES.

Sir,—We have been endeavouring to improvise a 'poison' bottle, instead of asking a practical bottle-maker to construct one for us.

Maw's guards or Baildon's india-rubber caps, though distinctive enough, have this great disadvantage, they require both hands of the dispenser, not only for their removal, but also for their readjustment. When one is busy, or on a market-day when customers are eager to catch a train, one cannot take time to refasten those safeguards. Such mechanical difficulties put in the way of the dispenser require more time than he can well afford.

The great desideratum is some simple contrivance which would permit us to measure liquor arsenicalis with as much facility as liquor bismuthi. I have long been of the opinion that an effective poison bottle could be made on the bayonet-catch or some such principle, to be locked or unlocked by giving the stopper half a turn, and this could be performed without bringing either bottle or measure to the counter.

The difficulties in the construction of such a bottle might easily be overcome by a practical bottle-maker. These bottles would, of course require to be longer in the neck than those in ordinary use, as the ground portion of both stopper and bottle would be lower than the catch. The projections on the stopper would correspond with the notches in neck of bottle, and these be so arranged that the stopper (on its insertion) could not go "home" till it was locked by giving the half turn. Some such contrivance would throw a mechanical obstacle in the way of an absent-minded or careless dispenser, and be equally adapted for narrow-mouthed or wide-mouthed bottles. SCOTUS.

Sir,—The safety-guard for bottles containing poison, suggested by your correspondent Mr. J. R. Summers, is very similar to the one I exhibited at the Liverpool Conference; but as mine possesses one peculiarity, which in practice would be found of importance, perhaps you will allow me space for a brief description. If there is simply an india-rubber band across the stopper, when once slipped off, it will be found difficult to be laid hold of again to replace in position; for this purpose a projecting knob is required to rest on the top of the stopper, which may be made in the following manner:—Take a $\frac{3}{4}$-inch brass paper fastener and bend back the two prongs in the form of hooks, on which must be hung the sides of an india-rubber ring, about an inch diameter; the hooks are then to be pressed together and the two loops tied round the neck of the bottle; or a second ring, about $\frac{1}{2}$-inch diameter, may be tied to the loops and passed over the neck of the bottle. I have had them in use for a long time, and am quite satisfied with their convenience and efficiency.

For the purpose of further distinguishing at a glance the articles belonging to the two parts of the "poison schedule," I make use of a red and also a green circular label, on which is a black cross, with the words "poison schedule," part one or part two, as the case may be; the colour indicating at once whether the article requires registration or a poison label only.

Liverpool, July 13th, 1871. GEORGE BARBER.

OVERDOSES.

Sir,—By a very simple arrangement, overdoses in prescriptions might easily be detected.

I would suggest that chemists should have written on every bottle the full B.P. dose of the drug contained therein. For instance, after the name extractum ergotæ liquidum should be written 30 minims; after hydrargyri perchloridum gr. $\frac{1}{8}$, and so on. By this means it would be impossible for an overdose to go unobserved, and in many instances time would be saved as the dispenser would not have to refer to the Pharmacopœia when doubtful of the dose. Of course, all preparations "not official" should be treated in the same way, as many of them being seldom used the dose would not be so familiar.

L. T. ASHWELL.

LEMON AND LIME JUICE.

Sir,—I think your remarks on my letter are hardly to the point, as they do not satisfactorily meet the question at issue. My communication was in reply to your paper asking for a substitute for lemon- and lime-juice, and I there stated what I had done, as also the reason which induced me to try the citrate of potash.

As far as my opinions on the matter are concerned perhaps some of them are not correct, and I am quite willing to withdraw my charge against lemon-juice and rum, which, perhaps, may be thought by some persons to be a very nice mixture, and taken with pleasure by sailors for the sake of the rum it contains; but still this does not at all settle the question as to the value of citrate of potash.

My reason for stating that citric acid was useless was due to the fact that the acid is not used as a substitute for lemon-juice, and also that various fruits and fresh vegetables are equally useful as lemon-juice, although none of them may contain citric acid. The same may also be said of fresh meat. The question then really seems to be, whether the value of these various bodies, as I stated in my letter, may not be due to the potash they contain in combination with an organic acid, either citric, tartaric, malic, etc., as the case may be.

I cannot see that any amount of laboratory work will settle the question; and after all it can only be solved by careful experiments at sea during a lengthened voyage. As far as I am able, I have attempted to find an answer to your query, and, as I stated in my former letter, must now leave it to others to determine by careful experiments whether the remedy I propose has any value or not.

ROBERT PALMER.

"*Chemicus.*"—It is supposed to facilitate the oxidation of the iron, and so increase the amount dissolved. Many excellent operators, however, do not find any advantage in this process over the old one of complete immersion.

R. S.—A certain amount of basic chloride is formed during fusion. This is decomposed by water into oxide and soluble chloride.

A. P. S.—You will find a formula for Composition Powder in the first volume of this series, p. 457, and for podophyllum pills in the present number.

"*Roy.*"—1. Mayne's 'Medical Vocabulary' (Churchills).—2. Piesse's 'Art of Perfumery' (Longmans).

C. D. C.—Perhaps the occurrence was owing to an accidental scratch, or the glass may have been imperfectly annealed. We cannot account for it in any other way.

"*Alumen.*"—See a paper on the "Detection of Alum in Bread," read before the Glasgow Chemists and Druggists' Association by Dr. Carter Moffat, Vol. I. p. 595.

R. G. Mumbray.—We suppose that there must have been some informality in the petition against the Pharmacy Act Amendment Bill, which you inform us was presented by Mr. Peek on behalf of the inhabitants of Richmond on Monday last, since its presentation is not recorded in the votes and proceedings of the House of Commons.

G. B. Cocking.—The letter sent for insertion in last week's issue reached us about six hours after the Journal had been printed.

S. W. N.—Tarragon vinegar is made by digesting the fresh plant in vinegar or dilute acetic acid. We are not aware of any substitute for the plant.

W. H. B.—Mix the powder with sufficient sulphuric acid to convert two-thirds of the lime into sulphate.

E. J. Beal.—We decline to advertise the practice referred to in your letter; and though we regret that any member of the Pharmaceutical Society should lend himself to such a proceeding, we can at present only hope that the business of a pharmacist will ultimately be regarded in such a light by all those engaged in it as to prevent the adoption of such a course by any one belonging to the trade.

"*Beta.*"—We regard the case referred to in your letter as one of the sale of an article of drysaltery, and we think it should not be regarded as competition with qualified pharmacists.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. A. Deck, Mr. T. H. Hustwick, Mr. R. Bannister, Mr. J. Inglis, Mr. F. Crace Calvert, "Alumen," "Aqua Destillata."

THE STRENGTH OF THE HYDROCYANIC ACID OF PHARMACY.

BY DR. W. A. TILDEN.

Having on several occasions noticed considerable deficiencies in the strength of hydrocyanic acid said to be B.P., that is represented as containing 2 per cent. of real acid, I have recently examined a few samples, with the view of comparing them together, and of ascertaining how far they diverge from the Pharmacopœial standard.

A weighed quantity was in every case introduced into a stoppered bottle containing water, and more than sufficient potash to convert all the HCN into KCN. An accurately standardized solution of nitrate of silver was then run in from a burette, till, after shaking, the last drop produced a faint opacity of the fluid. As in most cases two experiments were performed with the same sample, the close agreement of the results shows the accuracy of the method.

No.	Percentage of HCN.	
1	2·183	2·188
2	2·037	2·028
3	1·909	
4	1·521	1·526
5	·980	
6	·903	·904
7	·789	·796
8	·483	·484

The first three are what they should be; the fourth is only three-quarters of the strength required officially; the last four are quite unfit to use, and should be condemned. Pharmacists who employ for dispensing purposes hydrocyanic acid in such a condition as these four samples should not forget that they take upon themselves the responsibility of reducing the dose ordered by a medical man in his prescription to one-half, or as in the last case to less than one-fourth.

It is difficult to suggest a remedy for this kind of thing. The practice of testing all the more important preparations, both qualitatively and quantitatively, must become more common than hitherto among retail druggists; and in the case of articles like prussic acid, which is cheap, easily prepared, and in the dispensing of which accuracy is specially demanded, it seems desirable to renew the stock often enough to avoid changes of such a serious character.

THE OPTICAL ANALYSIS OF BEES-WAX.

BY HENRY POCKLINGTON, HULL.

A brief *résumé* of my observations and experiments in the optical analysis of *Cera flava* and *C. alba*, as found in the trade, may not perhaps be uninteresting or wholly valueless. It has been remarked to me that pure wax is not to be obtained in large quantities, and that wholesale dealers feel themselves secure against detection, provided they restrict their choice of adulterants within certain limits. To some considerable extent this is true; to so great an extent, indeed, that out of the very numerous samples that I have examined, all said to be "pure," there was not one but was more or less largely adulterated; and I have knowledge of firms who professed themselves able to supply any quantity of pure wax; but, being told that it would be submitted to a competent analysis, wrote, stating their regrets that they had no "pure" at present in stock.

During a conversation on microscopical subjects with my friend Mr. C. P. Gibson, M.P.S., of this town, this beeswax question cropped out, and my friend, himself an ardent microscopist, produced a number of slides of *Cera flava* and *C. alba* for my inspection, remarking, "they are all said to be pure, but one, at least, is very remarkable as regards the form of the crystals." A cursory glance convinced me that one specimen was very adulterated, and none of them, least of all the *C. alba*, appeared to me to be genuine. To obtain a sample of pure wax was now our difficulty, from which Mr. Gibson's assistant speedily extricated us, by obtaining from some friends who were beekeepers a small portion of absolutely unadulterated wax that had been prepared by them for their own use. My friend most kindly undertook to prepare for me, according to my directions, a series of slides, some being pure, others adulterated in defined proportions with suet, lard and stearine, the whole being put up in a similar manner, and carefully labelled. A slight examination of these slides by means of the microscope would show the least experienced observer that a slide of pure wax was a far less pretty microscopic object than a slide prepared from ordinary commercial wax. But this is hardly enough. More is required than a slight difference in prettiness to enable us to pronounce decidedly upon the presence or not of an adulterant. For example, it might be objected that the two slides were prepared from wax of a different nationality, and that the very different food of the bees in the one country caused a variation in the beeswax, which was shown by the slightly different arrangement of the crystals as seen under the micropolariscope. To satisfy myself that this was not a misleading element in the affair, I examined a considerable number of samples of commercially pure wax under a Beck's ¼-inch objective, using a Nichol prism for polarizer, and an exceedingly good tourmaline as an analyser. Under the ¼-inch, the form of the crystals in commercial wax, as in pure, are seen to maintain a strong individuality. The wax crystal is smaller, always less feathery in aggregation, and has slightly different (as yet undetermined) rotative powers. The wax crystals in an adulterated or commercial specimen can almost be pointed out one by one to an observer by means of an indicating eyepiece. Their separation is most complete and distinct. It is not easy, without carefully-executed drawings, to point out the difference between the forms of wax crystals and those of the stearine (in some form or other) with which wax is invariably adulterated. It may serve my purpose here, which is merely to suggest a means by which every chemist may act as his own detective in this matter, if I describe my mode of procedure.

The only requisites are a microscope of tolerably good workmanship, such as may be purchased of any of our leading opticians for a few pounds. The stage should either be itself capable of rotation or receive Swift's Blankley's* revolving stage, an ex-

* It is due to these gentlemen that I express my thanks for the courtesy with which they have placed apparatus at my disposal in working out certain microscopic problems, and in carrying out my suggestions.

ceedingly inexpensive but valuable adjunct to the polariscopist. The polarizer should be a good Nichol prism, the analyser, which *must* be capable of being rotated, may be either a tourmaline, Herapathite, or Nichol. Mr. Swift fits the Nichol prism in a manner singularly well adapted to polariscope researches, and, when specially requested, provides means by which the precise number of degrees over which the analyser is rotated may be measured without the necessity of carrying the prism in place of the cap over the eyepiece. A few glass slides, then covers and thick brass plate, are the remaining requisites. The first step should be to prepare a slide or two of known pure wax. Having cleaned the slip and cover perfectly, place the former on the brass plate (which should be at least half an inch thick), with the cover upon it as near the centre as possible. Place at the edge of the cover a small fragment of wax and slowly heat the plate by means of a spirit-lamp underneath until the wax melts. Extinguish the lamp, and allow the whole to cool. When the slide is cold remove it. Prepare slides of *commercial* stearine, of composite candle fat, suet and spermaceti in the same way, and label each as prepared. Mix with the pure wax various proportions of stearine, tallow, suet; mount slides and label. Finally, study each carefully under the micropolariscope, the prisms being crossed so that the field is dark, and rotate the slide by means of the rotating stage. When thoroughly familiar with the differences between these slides and the forms of the several crystals, the observer may proceed to the examination of commercial wax, and he will be singularly fortunate (according to my experience) if he discover a single *pure* specimen of commercial wax. *Cera alba* is, to my notion, the most adulterated, chiefly, I think—though, from my comparative neglect of this article I am not sure—with stearine. Spermaceti is also probably adulterated, but as yet I have not obtained a trustworthy standard specimen.

THE ECONOMIC USES OF MALVACEÆ.

BY ERNEST T. AGNEW.

The astonishing neglect of the valuable properties of this important Natural Order in British pharmacology is somewhat extraordinary, considering the extent to which our immediate neighbours employ them. No one species of the Order, with the exception of *Gossypium*, appears in our Pharmacopœia; whereas the French Codex enumerates five species, and twelve preparations therefrom, not including the celebrated "Pâte de Guimauve," which, curiously enough, contains nothing to identify it with its name, but is made as follows:—

White Gum . . .	1000	grammes.
White Sugar . .	1000	,,
Water	1000	,,
Orange-flower Water	100	,,
White of Egg . .	No. 12.	

Great care is necessary for a successful issue. The solution of gum and sugar should be evaporated over a water-bath to the consistence of thick honey, and the white of eggs, previously well whisked with the orange-flower water, should be added gradually, and the mixture constantly stirred till nearly solid. The result repays the trouble incurred, the fresh pâte being an universally-liked and deservedly-favourite remedy for irritation in the throat, larynx or fauces.

The common *Malva sylvestris*, so abundant everywhere in England, furnishes nearly as much mucilage as the *Althæa officinalis*, and furnishes a conspicuous example of credulous natures "going farther and faring worse." Flowers, leaves and roots all abound with it. The celebrated oculist, Dr. Desmarres, frequently prescribes a hot decoction of the root with which to bathe the eyes in any case of inflammation of those organs. A "*tisane*," or infusion of the flowers sweetened with sugar, is used on the Continent in lieu of linseed tea,—its agreeable flavour and greater efficacy particularly recommending it as a demulcent drink in fever, cold or gonorrhœa.

The *Lavatera arborea*, or Sea Tree-mallow, is frequently employed by the inhabitants of the coasts on which it grows. Its large deep-purple flowers covering the shrub, which always grows on small rocky islets, render it one of the handsomest of our indigenous plants. All parts of it are equally mucilaginous, and the petals yield a splendid colour when infused with hot water. The flowers of the *Althæa arborea seu rosea*, the Hollyhock of our gardens, are much used in Germany. They contain a red extractive and mucilage.

The *Althæa officinalis* ranks high in the estimation of most Continental practitioners. The powdered root is used chiefly as an excipient,—much, in fact, as liquorice root is used here,—and has the advantage of being white and nearly tasteless. A cataplasm of it is also officinal. The syrup is an agreeable vehicle for kermes, morphia and other active medicines. Guimauve lozenges are prepared with a mucilage of the plant, and dissolve in the mouth with a peculiarly balsamic and slimy effect. *Malva glabra*, *rotundifolia* and *sylvestris* are also officinal. Their flowers are used for *tisanes* or infusions, and are a component of the famous *quatre-fleurs* (*species emollientes*).

The Cotton-plant (*Gossypium*) is too well known to pharmacists to need any description. The oil is largely imported, being expressed from the seeds by means of heat. Its chief use, I am sorry to add, is to adulterate other more expensive oils.

The boiled root of the *Althæa*, after preparing the decoction, is highly palatable, and can be eaten with much relish as a vegetable. During a short historic period, in which hunger caused many of us to make some curious experiments with the esculent commodities of a pharmacy, we found the boiled marshmallow-root a very pleasant addition to horseflesh, much resembling salsify in flavour and appearance. How much esculent food is lost in this country through ignorance and prejudice is an economist's problem; but I am certain that boiled chickweed is superior to spinach, dandelion salad to endive, and marshmallow-root to parsnips. *Crede experto.* The hedges furnish food for thousands, but is science powerful enough to overcome prejudice?

PHARMACY IN PORTUGAL.

Dr. Ullersperger, of Munich, gives an account of the state of pharmacy in Portugal in 1869–70, which he divides into two parts, viz. the pharmaceutical instruction at the University of Coimbra, and the position of practical pharmacy. At the university five years' study are prescribed, viz. 1st year, inorganic chemistry; 2nd year, organic chemistry and analysis; 3rd year, natural philosophy (1st part) and botany; 4th year, natural philosophy (2nd part) and zoology; 5th year, mineralogy, geology, and mining. For practical instruction the university possesses museums for zoology, mineralogy, conchology, and for physics; also a chemical laboratory, and a splendid botanical garden, which may rival with any other in Europe. The last was founded in 1773, and is now under the direction of Dr. A. J. R. Vidal; the gardener is a native of Schleswig-Holstein, Mr. E. Goetze, who was recently sent to the Azores, whence he brought home many exotic plants.

There is also a museum for medical chemistry, which is open for pharmaceutical students, containing in two large rooms collections of apparatus and preparations. The dispensary attached to the university serves for practical instruction; it contains rooms for dispensing, the hospitals in connection with the university being supplied with medicines from here, store rooms and a large lecture-room. Dr. A. de Vascoricellas, the director, lectures here on pharmacy and materia medica for medical students; the pharmaceutical course in the laboratory lasts two years, while the third and fourth years are reserved for practice in the dispensary.

The want of a pharmacopœia in Portugal has been felt for a long time; true there was a Pharmacopea Regal published by Tavaxes in the last century, but it did not keep pace with the progress in science; it was followed by a Codigo Pharmaceutico, by Dr. A. Albano da Silveira Pintro, and in 1838 a commission was appointed to draw up a codex for medical men and pharmacists. The result of their labour was the Pharmacopœa Lusitana, but the one now in force is nothing more than a revised edition of Dr. Albano's Codex. The Sociedade Pharmaceutica hold their meetings at Lisbon; one of the leading members is Henrique José de Sousa Telles. There are several pharmaceutical journals in Portugal, the most important of which at home is the *Revista de Pharmacia e Sciencias Accessorias do Porto*, while the *Archivo de Pharmacia e Sciencias Accessorias da India Portugueza, publicado e redigido por Antonio Gomes Roberto*, professor of pharmacy at the medical school at Nova Goa, Portuguese India, represents the interests of the Transatlantic possessions; it appears in monthly numbers, and it may be interesting to give the contents of a recent number, as showing the position of the profession in the far away countries; they are, analysis of a mineral from the province Canacorea by Cabo de Rama, merely showing clay and iron pyrites; a paper on the climate of the island of Mozambique, by Dr. C. A. de Macedo e Valle; several formulas, such as syr. tolutanus, syr. sarsaparillæ, syr. rhataniæ, inf. aur. co. aquosum, liq. spir. tolutan., and letters on the medico-chirurgical school and on experimental physiology, and finally, a report on insalubrity by Sr. Bartholomew do Choras, and on stagnation of saline waters in Vargea Cadlem do Bairo Paudi Vaddo, by Dr. F. M. da Silva Torres.

As a special branch of science, pharmacy in Portugal is far behind England, Germany or France, and a wide field for investigation is still open, especially in two directions, viz. in organic chemistry, physiological as well as pathological, and in analyses of mineral waters, in which the country is particularly rich.

FLUID EXTRACTS AND THEIR MENSTRUA.

BY EDWARD R. SQUIBB, M.D.

(*Concluded from page* 65.)

FLUID EXTRACT OF CONIUM SEED, NOT OFFICINAL.

But should be. One hundred pounds of green unripe fruit or seed, yield about thirty-five pounds of dried unripe fruit, which when properly dried retain their green colour. The best fluid extract of this very tender and sensitive drug, is made by crushing the fresh unripe seed with a small proportion of stronger alcohol slightly acidulated with hydrochloric acid, and pressing out the liquid by a powerful press, and evaporating, without heat, by enclosing it over lime, until three pounds of the fresh unripe fruit is represented by one pint of the preparation.

An excellent preparation may also be made from the dried unripe fruit in fine powder, by repercolation with stronger alcohol slightly acidulated with hydrochloric acid.

FLUID EXTRACT OF ERGOT, OFFICINAL.

Ergot cannot be obtained in fine powder without material injury. It should be had in as fine a powder as practicable without drying, and this grinding should be done at the time when it is to be percolated. Skilfully repercolated with diluted alcohol acidulated with one per cent. of acetic acid, the preparation appears unexceptionable. A pint of the menstruum, at 25° C. = 77° F., weighs about 6824 grains, and a pint of the finished preparation weighs about 7224 grains, giving a difference of about 400 grains.

FLUID EXTRACT OF IPECACUANHA, OFFICINAL.

This preparation is very much in need of special study and research, the present formula being troublesome and uncertain in regard to the precipitation of the resin, and yielding a preparation not uniform in appearance and properties.

FLUID EXTRACT OF PAREIRA BRAVA, NOT OFFICINAL.

But should be. This drug from its density is a refractory substance to percolate. It should be in the finest possible powder, and be percolated very slowly with the mixture of alcohol, glycerine and water.

FLUID EXTRACT OF WILD CHERRY BARK, OFFICINAL.

This is, perhaps, the most troublesome of the officinal formulas, and requires more knowledge and skill than repercolation does. If the menstruum be watery enough, and contain but little alcohol, the reaction between the constituents of the bark for the production of hydrocyanic acid and oil of bitter almonds takes place during the maceration, and thus saves the circuitous route by emulsion of almonds. The mixture of alcohol, glycerine and water is well adapted to this percolation, and yields a preparation having much more of the sensible properties of the drug than the officinal process. It should also be made double the present officinal strength.

A pint of the menstruum weighs about 7540 grains at mean temperatures, and a pint of the preparation of full strength about 8290 grains, giving a difference of about 750 grains. Or, for the present officinal half strength, the weight of a pint would be about 7915 grains, with a difference of about 375 grains.

The hydrocyanic acid and oil of bitter almonds of this preparation seem to suffer spontaneous decomposition, as the proportion, always very small, appears to diminish somewhat rapidly. As the physician often needs these sedative constituents, they should be added at the time of prescribing.

FLUID EXTRACT OF RHUBARB, OFFICINAL.

The rhubarb should be in very fine powder, and be repercolated with the mixture of one part glycerine and three parts stronger alcohol. Many menstrua were tried with this drug, but none seemed to do as well as that indicated. A pint of the menstruum weighs about 6828 grains, and a pint of the finished preparation about 7328 grains, giving a difference of about 500 grains.

FLUID EXTRACT OF SARSAPARILLA, AND COMPOUND FLUID EXTRACT OF SARSAPARILLA, BOTH OFFICINAL.

Should be in fine powder, and be repercolated with diluted alcohol, and glycerine added to the weak residuary percolate in such amount as to constitute one-fourth the weight of the finished preparation. This should then be reduced to the proper extent by distillation, and the glycerine residue be added to the strong percolate.

The mezereon of the compound fluid extract is often complained of, and probably might be omitted without injury.

FLUID EXTRACT OF SENNA, OFFICINAL.

This preparation, made by the officinal process, is often complained of for want of purgative strength. In order to try the effect of stronger alcohol as a menstruum for senna, a portion was completely exhausted by the use of 18 pints of the alcohol. The residue was dried, and when taken by the writer in doses of 180 to 200 grains, proved purgative, and produced griping. Other portions were exhausted by weaker alcohol, and the residue tried in the same way, but the purgative power did not disappear entirely until the alcohol was reduced by the addition of half its volume of water. It appears, therefore, that the officinal diluted alcohol, as now used, or that which is a little stronger, as made by mixing equal weights of stronger alcohol and water, are one or the other proper for the repercolation of senna. The diluted alcohol has been tried and does well, but whether the other would be better has not been tried. The addition of glycerine, even in small proportion, overloads the preparation with mucilaginous extractive matter.

FLUID EXTRACT OF DANDELION, OFFICINAL.

The German bitter root is much preferred by the writer, and it should be in very fine powder. The officinal diluted alcohol, as now directed, dissolves an unnecessary proportion of the mucilaginous ingredients of the drug, and clogs the percolations. A mixture of equal weights of stronger alcohol and water answers better, and yields a good preparation.

FLUID EXTRACT OF UVA URSI, OFFICINAL.

Should be simply repercolated in very fine powder by the mixture of alcohol, glycerine and water. This menstruum seems well adapted to this drug.

FLUID EXTRACT OF VALERIAN, OFFICINAL.

Various mixtures of glycerine were tried for percolating this drug, but without success, nothing answering so well as stronger alcohol. English valerian yields a preparation of milder taste, and finer and more delicate odour. But the German or French drug, which gives a peppery impression to the tongue, is doubtless the more effective medicinal agent.

FLUID EXTRACT OF AMERICAN HELLEBORE, OFFICINAL.

This should be repercolated in very fine powder with stronger alcohol, and should always bear a red label.

FLUID EXTRACT OF GINGER, OFFICINAL.

This should be made from African ginger in very fine powder, and not from Jamaica ginger. The latter has a finer aromatic flavour, but the former is the stronger carminative. The menstruum should be stronger alcohol.

The difficulty and labour in making good fluid extracts has recently led to a proposition, chiefly advocated among the pharmacists of Chicago, to reduce the strength of these preparations by one-half, or to the present strength of the fluid extracts of cinchona and wild cherry bark. Although there are some good reasons for this proposition, yet in the writer's opinion it would not be a wise change. The popularity of these medicines, as a class, depends largely upon the convenience which they offer to country physicians of carrying their remedies in a small compass, and in a convenient form; and to give this and many other advantages up at this late day, after many of the difficulties and deficiencies have been discovered and remedied, would be to sacrifice much useful labour with the recognized advantages. Besides, one of the most useful of the directions in which progress in pharmacy is recognized, is in the concentration and condensation of medicinal agents.

One direction in which several of the fluid extracts might be improved, is by the addition of corrigents. Fluid extracts of cinchona and senna should have aromatics in full proportion added, and there should be a fluid extract of May-apple with belladonna or hyoscyamus, and aromatics.—*Proc. Amer. Pharm. Assoc.*

THE ACTION OF HYDROBROMIC ACID ON CODEIA AND ITS DERIVATIVES.*

BY C. R. A. WRIGHT, D.SC.,

Lecturer on Chemistry in St. Mary's Hospital Medical School.

It has been shown in Part I. of this research† that the action of hydrobromic acid on codeia gives rise, without evolution of methyl bromide, first to bromocodide, and secondly to two other new bases, termed respectively deoxycodeia and bromotetracodeia, the latter of which, under the influence of hydrochloric acid, exchanges bromine for chlorine, yielding a corresponding chlorinated base, chlorotetracodeia; when, however, the action of hydrobromic acid is prolonged, methyl bromide is evolved in some little quantity. By digesting codeia with three or four times its weight of 48 per cent. acid for five or six hours on the water-bath, vapours were evolved, which condensed by the application of a freezing mixture to a colourless mobile liquid, the boiling-point of which was found to be 10·5° to 11·5°, and the vapour of which burnt with a yellow-edged flame, exploded violently with oxygen, forming carbonic and hydrobromic acids; it becomes, therefore, of interest to examine in detail the action of hydrobromic acid on each of the three bodies produced from codeia under its influence.

I. *Action of Hydrobromic Acid on Bromotetracodeia.*

When bromotetracodeia hydrobromate is heated in a sealed tube to 100° with four or five times its weight of 48 per cent. hydrobromic acid for from six to ten hours, methyl bromide is found as a thin layer on the top of the tarry contents of the tube after cooling; by dissolving this tarry substance in water, and fractionally precipitating the liquid by strong hydrobromic acid several times successively, nearly white amorphous flakes are ultimately obtained, resembling in all their physical and chemical properties the bromotetracodeia hydrobromate originally employed. After desiccation, first over SO_4H_2, and finally at 100°, there were obtained numbers which correspond with those required for a base bearing the same relation to morphia that bromotetracodeia does to codeia; it is, therefore, provisionally named bromotetramorphia.‡

* Read before the Royal Society, June 15, 1871.

† Proc. Roy. Soc., vol. xxi. p. 317; PHARM. JOURN. 3rd Ser. Vol. I. pp. 867, 886.

‡ All combustions given in this paper were made by lead chromate and oxygen; except where otherwise stated, chlorine and bromine were determined by boiling with silver nitrate and nitric acid.

Hence the action of hydrobromic acid on bromotetracodeia is

$$\underbrace{C_{72}H_{83}BrN_4O_{12}}_{\text{Bromotetracodeia.}} + 4\,HBr = 4\,CH_3Br + \underbrace{C_{68}H_{75}BrN_4O_{12}}_{\text{Bromotetramorphia.}}$$

Carbonate of soda throws down from the solution of the hydrobromate a nearly white precipitate which rapidly oxidizes, and appears identical in all its physical properties and chemical reactions with bromotetracodeia.

When crude bromotetramorphia hydrobromate is precipitated by carbonate of soda, and the precipitate (after filtration and washing) redissolved in hydrochloric acid and fractionally precipitated twice or thrice by strong hydrochloric acid, white flakes free from bromine are ultimately obtained; these are the hydrochlorate of the corresponding chlorinated base, which is therefore termed chlorotetramorphia. After drying at 100°, numbers were obtained which led to the formula $C_{60}H_{75}ClN_4O_{12}, 4\,HCl$.

Converted into platinum-salt, and dried at 100°,—

0·4235 grm. gave 0·0840 Pt = 19·83 per cent.

The formula $C_{63}H_{75}ClN_4O_{12}, 4\,HCl, 2\,PtCl_4$ requires 19·72 per cent.

When codeia is heated on the water-bath with three parts of 48 per cent. hydrobromic acid for five hours, and the portion of the precipitate thrown down by carbonate of soda and insoluble in ether is dissolved in hydrochloric acid, and fractionally precipitated several times by excess of stronger acid, flakes are obtained which, on drying at 100°, yield numbers intermediate between those required for chlorotetracodeia and chlorotetramorphia, leading to the formula,—

$$C_{70}H_{79}ClN_4O_{12}, 4\,HCl.$$

Converted into platinum-salt, and dried at 100°,—

0·4830 grm. gave 0·0935 Pt = 19·36 per cent.

The formula $C_{70}H_{79}ClN_4O_{12}, 4\,HCl, 2\,PtCl_4$ requires 19·40 per cent.

Whether this is only a mixture of chlorotetracodeia and chlorotetramorphia hydrochlorates, or is one compound, is open to doubt: assuming that it is not a mixture, the name chloro-dicodeia-dimorphia might be applied to the base. It appears *à priori* probable that the following double series of bases should be obtainable by successive methyl eliminations:—

Bromotetracodeia	$C_{72}H_{83}BrN_4O_{12}$
	$C_{71}H_{81}BrN_4O_{12}$
	$C_{70}H_{79}BrN_4O_{12}$
	$C_{69}H_{77}BrN_4O_{12}$
Bromotetramorphia	$C_{68}H_{75}BrN_4O_{12}$
Chlorotetracodeia	$C_{72}H_{83}ClN_4O_{12}$
	$C_{71}H_{81}ClN_4O_{12}$
Chloro-dicodeia-dimorphia .	$C_{70}H_{79}ClN_4O_{12}$
	$C_{69}H_{77}ClN_4O_{12}$
Chlorotetramorphia . . .	$C_{68}H_{75}ClN_4O_{12}$

Out of these ten bases four have been prepared, and a substance corresponding in composition with a fifth (chloro-dicodeia-dimorphia) has also been obtained; but from the great similarity in properties between all the five substances and their high formulæ, it is clear that no certainty as to the purity of the missing intermediate bodies could exist, and therefore it was not thought advisable to attempt their formation.

II. *Action of Hydrobromic Acid on Bromocodide.*

When bromocodide hydrobromate (prepared by two hours' digestion of codeia with three times its weight of 48 per cent. HBr, precipitation by sodium carbonate, and extraction with ether, etc.) is heated with four to six parts of the same acid to 100° for five or six hours either in a sealed tube or in an open flask, methyl bromide is copiously evolved; the tarry product, dissolved in warm water, and precipitated by sodium carbonate, is for the most part insoluble in ether, the insoluble portion having all the properties of bromotetramorphia; the ethereal extract shaken with HCl or HBr yields a viscid liquid, which, on standing, becomes filled with crystals consisting apparently of a mixture of the hydrochlorates, or hydrobromates, of deoxycodeia and a lower homologue, the latter predominating when the digestion is performed in an open flask. Attempts to prevent the formation of the lower homologue by continuing the digestion with HBr for only two or three hours did not succeed, as the large quantity of unaltered bromocodide in the ether extract obtained prevents the separation of the crystalline hydrochlorate or hydrobromate of deoxycodeia, and hitherto no method of separating the deoxycodeia salt from its lower homologue has been arrived at.

The following numbers were obtained by the analysis of these crystals after re-crystallization from hot water to free them from adhering bromocodide salt:—

Specimen A, prepared in sealed tubes, digested six hours at 100°:—

0·3185 grm. gave 0·7850 CO_2 and 0·1970 H_2O.
0·2200 grm. gave 0·1025 AgCl.

Specimen B, prepared in an open flask, digested six hours at 100°:—

0·2825 grm. gave 0·6920 CO_2 and 0·1660 H_2O.
0·2260 grm. gave 0·1085 AgCl.

Calculated.						Found.	
Deoxycodeia.			Deoxymorphia.				
C_{18} . . .	216	67·60	C_{17} . . .	204	66·77	67·22	66·80
H_{22} . . .	22	6·89	H_{20} . .	20	6·55	6·87	6·54
N . . .	14	4·39	N . . .	14	4·59		
O_2 . . .	32	10·01	O_2 . . .	32	10·47		
Cl . . .	35·5	11·11	Cl . . .	35·5	11·62	11·53	11·83
	319·5	100·00		305·5	100 00		
$C_{18}H_{21}NO_2HCl$			$C_7H_{19}NO_2HCl$				

The hydrobromate, prepared from the same batch as specimen B above, gave the following numbers after drying at 100°:—

0·3260 grm. gave 0·7010 CO_2, and 0·1720 H_2O.
0·2730 grm. gave 0·1465 AgBr.

Calculated.						Found.
Deoxycodeia.			Deoxymorphia.			
C_{18} . . .	216	59·34	C_{17} . . .	204	58·29	58·64
H_{22} . . .	22	6·95	H_{20} . .	20	5·71	5·86
N . . .	14	3·84	N . . .	14	4·00	
O_2 . . .	32	8·79	O_2 . . .	32	9·14	
Br . . .	80	21·89	Br . . .	80	22·86	22·83
	364	100·00		350	100·00	
$C_{18}H_{21}NO_2, HBr$			$C_{17}H_{19}NO_2, HBr$			

From the above numbers, and more especially from the percentages of H, Cl, and Br found, it appears that while specimen A may have contained some little quantity of deoxycodeia, specimen B must have consisted almost wholly of the lower homologue; to this body the name deoxymorphia may appropriately be given (provisionally), to indicate that its composition bears the same relation to that of morphia as deoxycodeia to codeia.

The numbers required for apomorphia salts are very close to those actually obtained above, viz., for hydrochlorate C = 67·22, H = 5·93, Cl = 11·70; and for hydrobromate C = 58·62, H = 5·17, Br = 22·99; but the entire absence of emetic properties in all these specimens, as observed by Dr. Michael Foster, conclusively proves that this base could not have been present.

Further research is required before it can be decided with certainty which of the three oxygen atoms in codeia is removed in the formation of deoxycodeia; the production of deoxymorphia with simultaneous evolution of methyl bromide, however, indicates that the oxygen that links the methyl group to the rest of the codeia residue is still present in deoxycodeia and deoxymorphia, while the production of both from bromocodide renders the following formulæ probable:—

Codeia. $C_{17}H_{17}NO \begin{cases} OH \\ O.CH_3, \end{cases}$ Bromocodide. $C_{17}H_{17}NO \begin{cases} Br \\ O.CH_3, \end{cases}$

Deoxycodeia. $C_{17}H_{17}NO \begin{cases} H \\ O.CH_3 \end{cases}$ Deoxymorphia. $C_{17}H_{17}NO \begin{cases} H \\ OH; \end{cases}$

so that deoxycodeia probably bears to codeia the same relation as free hydrogen, H_2, to water, $H.OH$; or as acetic acid, $\frac{CH_3}{CO.OH}$, to glycollic, $\frac{CH_2.OH}{CO.OH}$; bromocodide corresponding similarly to hydrobromic acid, HBr, or to bromacetic acid, $\frac{CH_2Br}{CO.OH}$.

Experiments are in progress to gain further insight into the structure of the group $C_{17}H_{17}NO$. By the action of hydriodic acid on codeia methyl is eliminated as iodide, and the elements of free hydrogen and those of HI are added on to this group; from which, as well as from the easy polymerization to form tetracodeia bases, it appears probable that some at least of the 17 carbon atoms are connected together somewhat after the fashion of ethylene or acrylic acid, which unite readily with HI, HBr, H_2, etc. Again, the oxidizing action of $AgNO_3$ on chlorotetramorphia is accompanied by the production of CO_2, which renders it not improbable that the third oxygen atom exists either as the group $[CH(OH)]''$ or as CO''.

On carefully examining, side by side, the qualitative reactions of the hydrochlorate B and those of a specimen of pure deoxycodeia-salt from codeia (without evolution of methyl bromide), not the slightest difference was discernible between the two; in their physiological actions, too, as observed by Dr. Michael Foster, the two bodies seemed perfectly alike, both being utterly dissimilar from apomorphia, from which in all other respects (qualitative reactions, percentage, composition, etc.) they differ either not at all, or extremely little.

THE MODERN ASPECTS OF THERAPEUTICS.*

BY WALTER G. SMITH, M.D.

It must be allowed that the reproaches which have been so often levelled against the *practice* of medicine have had much foundation in the past history of therapeutics, and all will re-echo Sir T. Watson's opinion, that "certainly, the greatest gap in the science of medicine is to be found in its final and supreme stage—the stage of therapeutics." Some of its keenest satirists have been physicians of the highest eminence and most varied acquirements, and, on the whole, it must be admitted, that the improvement of therapeutics, contrary to the other arts and sciences, "bears no proportion to its antiquity." It is the consciousness of this disproportion which damps the spirits of so many in the profession, and which has led to so much distrust and doubt. Dr. Radcliffe used to say that "the whole art of physic, for which he had a profound contempt, might be written on one sheet of paper," and it is not so long since the late Sir W. Hamilton, of Edinburgh, asked the question:—"Has the *practice* of medicine made a single step since Hippocrates?" a revival of the older query, *an datur ars medicinæ?*

There are many evidences that the need for a more careful study of therapeutics is urgently felt by the body of the profession at large. In 1865, the physiological sub-section of the British Medical Association drew up a memorial to the General Medical Council praying the Council "by pecuniary grants, and the appointment of suitable persons, to undertake investigations into the physiological action of medicines." This memorial was supported in the council by the Regius Professors of Physic in the Universities of Dublin and Oxford, but was negatived on the ground of want of powers in the council to comply with the petition.

A sub-committee was then appointed by the British Medical Association, and the results of its labours are seen in the elaborate report brought out by Dr. Hughes Bennett, on the action of mercury, podophyllin, and taraxacum on the biliary secretion. About the same time the Royal Medical and Chirurgical Society intrusted the examination of the method of subcutaneous injection to a committee, and the valuable observations embodied in their report furnish the most satisfactory data which we possess respecting this method. Quite recently the Medical and Psychological Association of Edinburgh have appointed a committee for the purpose of taking into consideration, among other things, the medical treatment of insanity, and they suggest propositions for combined therapeutical investigation, and ask for special information on the action of chloral. The Clinical Society of London owes its establishment in 1868, to the expressed want of more real knowledge on the various remedies in daily use, and the appearance of numerous detached papers, and of some works of merit on the doctrines and requirements of therapeutics testify to the deep-seated interest which now attaches to the prosecution of this subject.

I propose, now, briefly to inquire what are the resources at our command, and how far it may be said that therapeutics has advanced within the last quarter of a century, what are the hindrances to its progress, and, more particularly, in what directions we may hope for still further and more solid advances than have yet been gained.*

To avoid entering upon too wide a field my observations will be chiefly confined to the domain of what may be called medicinal therapeutics, *i. e.*, of remedial agents as directly applied to the treatment of disease, and accordingly the steady progress and increased knowledge of sanitary science and preventive medicine, the splendid results of operative surgery, and the development of state medicine, will be passed over without comment.

The retrospect of the history of therapeutics for centuries past, is, in many respects, not encouraging, and one can scarcely help wishing that much, if not most, of what is called the accumulated experience of ages were swept clean out of remembrance, so overladen is it with confusion, misstatements, and unproven theories. In fact since the prevailing ideas as to the action of drugs became in some degree fixed at a time when pathology was less exact than it is now, when there were no such accurate means of testing the real effects of remedies, and when physics and chemistry were in their infancy, we cannot avoid insisting on the necessity for renewed observations, carried out under better auspices, and with a better directed aim.

Yet it will be conceded that the materia medica abounds in agents by means of which very remarkable effects can be produced on the human frame, and a speculative mind might engage itself in showing that the possession of such powers by various medicines is an argument in favour of our being intended to exercise a due control over the progress of disease. Even as it is we can, at will, exalt or depress the action of the heart, the great fountain of life, and can, to some extent, control the capillary circulation; we can compel the stomach to eject its contents, and the intestines to discharge their excreta. We have agents that act on special functions

* Thesis for the degree of M.D., 1870. Read before the Medical Society of the College of Physicians, March, 1871.

* For many suggestions I am especially indebted to, and have largely made use of Sir W. Jenner's admirable address on medicine, delivered last year in Leeds, and Dr. Rogers' recent able work on therapeutics.

of the encephalon, on the spinal cord, on the sensitive nerves, and purely on the motor nerves. By suitable means we can increase or diminish the exhalation from the skin and mucous membranes, and can alter in quality and quantity the secretions of many important glandular organs. At pleasure we can contract or dilate the pupil of the eye, can stimulate striped and unstriped muscles, can poison some internal parasites with certainty, and can aid in the elimination of metallic poisons from the body. And, let it be observed, that not only have we these and other powerful means at our disposal, but that, in many, very many cases, we have the knowledge *how* to apply them to the treatment of disease with benefits which cannot be gainsaid, and in a few cases we know *why* we so apply them.

Our theories as to the nature of disease are undergoing a profound change, necessarily followed by corresponding modifications in the way in which we endeavour to meet or anticipate it. The notions of elimination and allopathy, of antidotes and of counter-irritation, have all their measure of truth, and are all usefully applied in practice, but it is to be hoped that none of them will ever again be raised to the rank of a system to cramp and fetter our ideas. As a positive and well-founded advance in the doctrines of therapeutics, it could easily be shown that certain injudicious or noxious lines of treatment have been abandoned, and that, in general, the habit of over-drugging has been given up. This beneficial change is due partly to a more accurate acquaintance with the local causes of disease, *e.g.* the parasitic skin diseases, partly to a more intimate knowledge of the pathology of disease, *e.g.* chronic pulmonary phthisis, and partly to a recognition of the principle that we are not to treat our patients as so many sponges doomed to soak up the maximum quantity of medicine possible, but, as living beings, whose functions are disordered by disease, and whom we seek to restore to health by aiding the natural tendency to recover, and by striving to modify the direction of action of the natural forces of the body. We know now that a large number of acute diseases occurring in previously healthy persons naturally run a definite course and tend to spontaneous recovery, in the absence of or even in spite of misdirected drugging, and we have recognized that certain acute diseases supposed to be of indefinite duration lie within appointed limits. We, therefore, by this advance in knowledge, avoid drawing false conclusions as to the efficacy of drugs in particular maladies, and although we do not pretend to be able to strangle acute disease by specifics, or suddenly arrest the cycle of morbid action, much still remains for our art in meeting special symptoms and controlling intercurrent complications. Sometimes advances in knowledge teach us a more correct appreciation of the composition and mode of action of drugs, or at least displace a faulty explanation. This certainly is a gain, and we know too little yet to see how far the application of the physical processes, dialysis, diffusion, and osmosis may before long enlighten some of the dark recesses of therapeutics.

Among the tributes levied from chemistry and natural history, we can reckon carbolic acid and its compounds, the alkaloids, the bromides, permanganate of potassium, sulphurous acid, and the sulphites, the whole group of anæsthetics, chloroform, ether, bichloride of methylene, nitrous oxide, and nitrite of amyl, Calabar bean, glycerin, pepsin, santonin, podophyllum, and lastly chloral, and its allies bromal and iodal. The mention of the class of alkaloids suggests the thought that very great benefit would, doubtless, accrue from the more extended use of the alkaloids in the room of the crude vegetable products from which they are derived. Our therapeutical experience would be rendered infinitely more accurate by the employment of these definite active principles which are chemically stable, and whose dosage can be exactly proportioned, and the differences which are often asserted to exist between the active principle and the crude drug itself would doubtless be found to be much less considerable than is generally thought. In the case of belladonna and conium, for example, the efficacy of these drugs is fairly and fully represented by their respective alkaloids, and even in the case of a complex substance like opium which contains several organic bases of different properties, it would be quite possible, after proper investigations to combine these bases in a compound solution so as to represent perfectly the action of the crude opium. As illustrations of the confirmation and extension of the curative powers of single drugs we can adduce the mass of evidence that now exists as to the respective value of mercury and iodide of potassium in different stages of syphilis, and of mercury especially in infantile syphilis, of the utility of arsenic in the *relapsing* skin diseases, of bromide of potassium in epilepsy, and certain other abnormal conditions of the brain and sexual organs, of quinine in periodic diseases other than ague, and of ipecacuanha in dysentery. We are better acquainted with the action of digitalis, opium, belladonna, hyoscyamus, and conium, and there is a clearer understanding gaining ground as to the worth and indications for the employment of alcohol in the treatment of disease.

The uses of iodide of potassium have been brought into greater prominence, and have been more sharply defined, and amongst the results "we may boast the disappearance of radesyge in Norway, of yaws in our West Indian colonies, and of most of the severe forms of tertiary syphilis at home." Since the more important of these drugs are of quite recent introduction, they are to be looked on as but an earnest of the harvest we are yet to reap from the domain of the natural sciences. Improved modes of administration are only second in importance, and hypodermic injection is an aid for which we cannot be too grateful, triumphing especially in the relief of painful and spasmodic affections. Lastly, a discrimination between the properties and uses of the direct and induced currents, *i.e.* of galvanization and faradization, has led to most important and gratifying results in the treatment of such formidable diseases as epileptiform neuralgia, infantile paralysis, and progressive muscular atrophy. It is proved that it is possible and feasible to galvanize directly the brain and spinal cord, and the galvanic irritation of the sympathetic nerve may yet furnish us with a powerful lever for controlling the nutrition of even remote parts.

Many circumstances have contributed to clog the progress of therapeutics, some of which belong to the inherent difficulties of its investigations, while others, and that a large portion, are due to the ignorance and incompetence of those to whom we should look for aid. The fallacies connected with the application of the inductive method of reasoning to the science of medicine, and the sources of error in practical and theoretical medicine, have been well exposed by Sir G. Blane and by Dr. Barclay, and I would merely remark that the principles enunciated by these authors, while they are the philosophical basis of the practice of physic, constitute the best answer to morbid scepticism on the one hand, and vulgar credulity on the other.

Faulty modes of preparation, and the use of entirely worthless compounds, are fruitful sources of error, and we can point in illustration to the investigations of Dr. Harley on the Galenical preparations of conium, in which he proves the absolute valuelessness of the extractum conii. Again, the assemblage of a number of active drugs in a prescription, often introduced at random, is destructive to a right appreciation of the effects of medicines; and, as a rule, the principle of combination should not be extensively tried till we are in a better position to estimate justly the influence of certain drugs on special diseases.

(*To be continued.*)

PRESSED BEEF AND DESICCATED BEEF-JUICE.

Baron Liebig conceived the idea of extracting from the wild cattle of South America those substances to which meat owes its characteristic properties, and conveying them to the ill-nourished populations of Europe. The so-called extract of meat was to be made, sent over to Europe, and distributed among the labouring classes, whose cheerless fare was thereby to be rendered stimulating, and equivalent to an animal diet. From the entire ox only eight or ten pounds of the Liebig's extract are procurable, but these eight or ten pounds of extract are very potent, and will animalize a mountain of vegetable food. The plan has, to some extent, answered. European food has been enriched with animal products from South America, and, in token of the success of the enterprise, the Liebig's Extract Company paid an 8 per cent. dividend some time ago. There are, however, difficulties in the way. The great bulk of the carcass—all the nutritive part, as distinguished from the stimulating extract—is thrown away, or converted into manure, and, in those hot climates, constitutes a serious drawback, involving considerable outlay for its proper disposal. On the other hand, the extreme concentration of Liebig's extract is a hindrance to its proper employment by the poorer classes in Europe. At present the benefit has been almost confined to invalids and the wealthy and middle classes, and has hardly reached the poorer people, who ought to be the chief recipients of it.

A new process for accomplishing the objects above referred to has just been brought out by Mr. Henley, a well-known engineer, and a company, called "The Pressure Meat Preserving Company," is being formed to work it.

Flesh, in its natural condition, consists of about 75 parts of water and 25 parts of solids. Mr. Henley proposes to remove the greater part of the water, whereby the meat will be reduced to one-half of its original weight (without loss of substance), and will be preserved at the same time. We have just tasted some of it, which had been kept for about a month in a chemical laboratory, and can speak to the soundness of its condition. The novelty in Mr. Henley's process is the employment of powerful pressure as a means of making the drying possible. In six hours the bullock which walks into the slaughter-house may be put on board ship in the shape of a highly dried pressed beef and desiccated beef-juice.—*The Lancet.*

ANNUAL DINNER OF THE EMPLOYÉS OF MESSRS. BURGOYNE, BURBIDGES AND CO.

The annual Excursion and Dinner of the persons employed by the above firm took place on Saturday last. The place selected for their visit was the Downs Hotel, Epsom.

Among the amusements provided for the entertainment of those present were walking, running and jumping matches, prizes for the winners in which were furnished by the liberality of the firm. One of these prizes was a handsome silver cup on an ebony stand; another, for the visitors—won by Mr. J. K. Pitt, the cork-merchant, —was an opera-glass. At the dinner-table the chair was occupied by Frederick Burbidge, Esq.

Indian Agriculture.—The culture of bamboo for paper-making and other purposes is being promoted by the Government of Central India. The Indian Government is buying land in the hill district of the Neilgheries for a spice plantation. Colonel Boddam has proposed the cultivation of the sunflower in Mysore. It is very successful in France. Government has sent out six more Scotch gardeners for experimental cotton-growing. These men have answered very well.—*Nature.*

THE PHARMACY BILL.

The following circular, treating of the views of the Manchester Defence Association on the present state of the question of poison regulations, and of the course it intends to take in the event of any further attempts at legislation on the subject, has been forwarded to us for publication:—

"63, *Piccadilly, Manchester, July*, 1871.

"Dear Sir,—The withdrawal of the Pharmacy Bill by the Government is a cause for congratulation to all the members of the trade who have so earnestly and effectually resisted its enactment. This result has been attained through the powerful opposition inaugurated by the Chemists' Defence Association, and carried on with so much unanimity and cordiality conjointly with the *Metropolitan* and *West of Scotland Defence Associations*, and promptly seconded by local organizations in all parts of the kingdom.

"It is the intention of this Association to continue its existence, to be ready to resist any future attempt on the part of Government to unnecessarily interfere with the internal management of our business.

"We have been much encouraged by the keen appreciation of the points at issue, and by the great amount of support we received from members of Parliament, and we unhesitatingly affirm that if opposition be again required, with the active and zealous assistance of friends throughout the country, we shall be able successfully to resist the passing of any measure, similar to or of so objectionable a character as that so happily withdrawn.

"We do not wish a renewal of the conflict, and we fervently trust that the wisdom of Government may obviate this necessity. Such a contest is undesirable, but we believe it to be our duty to boldly face the difficulty should it again arise, that our trade may retain its just measure of independence, be free from the undue and needless interference of the Privy Council, with the liberty to carry on our business with intelligent prudence and self-reliance which no arbitrary legal restrictions, however ably devised or fenced round with penal clauses, could so well secure.

"We take this opportunity of calling your attention to the fact that our opponents, whilst advocating with a zeal difficult to account for, the legal compulsory regulations for the storage and dispensing of poisons contained in the withdrawn Bill, have not been able, neither have they attempted, to bring forward any evidence that the public safety is jeopardized by the present condition of things, or that abuses exist to warrant Government in bringing forward the recent measure.

"It is incomprehensible how the declaration could be made by any person that the objections to the Bill had been completely removed by the amendments, whilst the penal clauses for the non-observance or infringement of the regulations, and the absolute power of the Privy Council and of the Pharmaceutical Council were retained. These are the essential principles contended against by this and kindred Associations, whose action has been endorsed by the approval of a vast majority of the chemists throughout the country.

"We trust that the question is settled, as we quite agree with the advocates for the imposition of the objectionable regulations that a settlement is desirable, and we hope that both they and the Medical Department of the Privy Council will read the signs of the times, and forbear the one from attempting to impose restrictions on our liberty alike unjust and unnecessary, and the others from encouraging such unwise attempts.

"We invite you to continue your membership of our Association if already enrolled, or to join our ranks, and by adding to our numbers to increase our influence, and sustain our efforts should the course of events require further action.

"Signed on behalf of the Executive Committee,

"ROBERT HAMPSON, *Hon. Sec.*"

The Pharmaceutical Journal.

SATURDAY, JULY 29, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed* "*Pharm. Journ.*"

THE PRESS AND THE PHARMACY BILL.

WHILE the leading medical journals maintain a discreet silence in reference to the fate of the Pharmacy Bill, which is at least consistent with the prevailing difference of opinion among those to whom it applies more especially, there is one exception to this course which we cannot omit to notice because it appears to be a totally unnecessary and gratuitous attempt to aggravate a contest which is already too dominant.

The journal to which we refer not long ago announced that Mr. FORSTER had only to lift his finger to make the Pharmacy Bill law, and at the same time predicted that he would do so in spite of everything. To such expressions of opinion or desire we offer no objection, but we do strongly protest against such perverse misrepresentation and defamatory comments as the following, where the same journal declares that this Society—

"has cast away any claim they might have had to consideration, and we trust Mr. Forster will trouble himself no longer with diplomacy, but exercise all his influence to do justice, whether the chemists and druggists like it or not. A larger issue than poison-protection is at stake, for it has now to be decided whether the Government is able to deal *with an opposition dictated, not by any principle, but by self-interest and carelessness for the public interest.* We never doubted that Parliament will support the Government in the effort, and we do not think that the fatuous proceedings of the Society have even the prospect of success to excuse them."

The italics are our own, but we abstain from comment on the quotation, since that would involve the use of more emphatic terms than we desire to appear in these pages, and because we think republication of the paragraph will alone ensure the condemnation it deserves.

Equally objectionable are the following remarks, given editorially in the same journal this week:—

"Mr. Forster makes rather a poor show just now. He talked very loud, and blustered a good deal, and now his superior officer, without hesitation, puts a stop to his threatened onslaught. Meanwhile, we are encouraged to see that the 'Party of Order,' who have voluntarily adopted precautions against poisoning, and don't wish to be slovenly, are coming to the point, and the *Pharmaceutical Journal* is, after the example of the *Times*, throwing out feelers for a change of policy from opposition to adhesion. A letter in favour of the amended Bill is published in that periodical this week, and it bears the signatures of almost all the large respectable chemists in London, and many in the country. Thus the opposition is narrowed to the limits of the small retail druggists, and loses so much of its force that we have reason to believe that it will lack power eventually to defeat the reform."

We cannot perceive the necessity for the tone manifested by these quotations, and feel convinced that the treatment of the subject in such a manner is extremely mischievous and reprehensible.

The *Ashton Reporter*, in an article on this subject, takes the view held by opponents of the Bill, and after remarking that the honourable members of her Majesty's Privy Council are not those to whom the best method of storing and dealing with poisons—or, as it may be expressed, the best shop-keeping arrangements—are very likely to occur, goes on to say—

"Even the medical department of that body has no practical acquaintance with the subject. Quite as suitable would it seem for the chemists of the kingdom to issue regulations for the surgeons or dentists in their difficult operations, or to venture upon a bolder stroke, and give advice to her Majesty's Privy Councillors upon the despatch of public business. Notwithstanding the incongruity, however, Government stood committed to a Bill which undertook to teach chemists a very elementary, though responsible, branch of their business. This could not be borne. Of course the trade was convulsed, and resisted the threatened interference. Petitions were hastily and numerously signed, and deputations from all parts of the country were despatched to confer with members of Parliament in London. A few days' canvass satisfied the resisting body that the Pharmacy Act never could pass the Commons. Here and there a hanger-on by authority attempted to justify the measure, but several influential representatives, headed by Mr. Jacob Bright, who introduced a large deputation, were received by Mr. Forster, and frank explanations were given, strengthening the opinion that the Pharmacy Bill must be either amended or withdrawn. Conspicuous by his courtesy and heartiness amongst those who accompanied the deputation to the Minister was Mr. T. W. Mellor, member for Ashton. He had presented a petition to Parliament, signed by every chemist in this borough, where chemists are supposed to be equally alive to their own and the public interests; and had placed his services very warmly at the disposal of his constituents to frustrate this scheme of surplus legislation. The Minister listened with attention, and promised further consideration of the measure. Meanwhile agitation spread, and members of Parliament were urged by petition and remonstrance, as well as by deputation, to resist the Bill. The opposition was becoming formidable, and the situation somewhat ridiculous. Here was the Privy Council trying to arrange the shelves of a druggist's shop. *Punch* might be on the look-out for a cartoon. Yielding to the great pressure from without, or perhaps awakening to the consciousness that the trained and experienced servants of the public are the best qualified to discharge responsible duties, an amended Bill was substituted for the original. This amended Bill, born in an emergency, survived only a few hours, and is already in an advanced state of decomposition. The public did not ask for it, and does not need it. The trade is able to take care of its poisons, and of itself. The Government has more legitimate children than it can provide for, and certainly members of Parliament, especially those of the opposition, must have perpetrated a certain deed had not these poor little Bills, by crowd-ing together at the close of the session, happily smothered each other.

"English institutions, like Englishmen, flourish the best away from the shade of Governmental protection or management. They require but freedom from restraint, and fair opportunities for development. Let there be a sense of duty and responsibility leading up to self-reliance and effort, and these will prove the surest guarantees both of personal success and of public advantage. A Pharmacy Bill that should substitute routine for alert attention would be fraught with inevitable mischief. A merely mechanical system, enforced by extraneous authority, is vastly inferior to a system which has grown up with existing requirements, and been gradually adapted to them. We do not pretend to say that the hands which are trusted to mix our physic and vend our poisons are always wisely guided, but upon the whole we would rather commit ourselves in such matters to the care of a very ordinary chemist than incur the risk of being experimented upon by an extraordinary Privy Councillor; and hence we congratulate our readers upon their deliverance from the Amended Pharmacy Bill."

THE METRIC SYSTEM OF WEIGHTS AND MEASURES.

The decision of the House of Commons on Wednesday rejecting the Bill to establish compulsorily the Metric System of Weights and Measures, brought in by Mr. J. B. Smith, is probably not entirely unsatisfactory to the supporters of the measure. That the second reading should be refused only by the small majority of five, notwithstanding the attempt of the Government to shelve the Bill, by a promise to deal with the subject next year, appears to show that public opinion is gradually tending in favour of the adoption of some such plan. For the convenience of our readers we give a short *résumé* of the Bill. It proposes that after a time fixed by Parliament the present imperial and all local or customary weights and measures shall be abolished, and the metric system, which is now permissive, shall be made compulsory. To this end, it directs that the unit of lineal measurement shall be the "metre," verified by comparison with the original standard in Paris; that the unit of surface measurement shall be the "are," equal to the square of ten "metres;" that the unit of the measure of capacity, for liquids and dry goods, shall be the "litre," equal to the cube of the tenth of the "metre," and that the unit of weight shall be the gram, of which a standard is to be prepared, to be verified by comparison with the original standard in Paris.

At the expiration of the time fixed, it is to be illegal to use any other denomination of weights and measures than those specified in the Bill, under a penalty of ten shillings for each offence. Any person who shall print any price list or price current, or any journal or other paper containing a price list or price current, in which the provisions of this Bill are not complied with, is to be liable to a penalty of ten shillings for every copy of such price list, price current, journal or other paper he shall publish.

The Bill also provides for the preparation and publication of accurate tables of comparison, showing the proportions between the weights and measures and those proposed to be established by the Bill.

The names on the Bill, besides Mr. J. B. Smith, are Sir Charles Adderley, Sir Thomas Bazley, Mr. Graves, Mr. Baines, Mr. Albert Pell, Mr. Muntz and Mr. Dalglish.

Of course, in the discussion of so wide and important a question, it is desirable that every argument should be carefully considered; but we are sorry to notice the appearance of an intention to make political capital out of it by an affected consideration for the convenience of the lower classes, and the suffering and loss the Bill would entail upon them. To use an illustration given by one honourable member, and with all deference to those who urge this view of the question, we think it very problematical a working man would continue to pay for the half-litre of beer the same as he now pays for a pint, although he would only receive about seven-eighths of the quantity. Such matters would undoubtedly be regulated by the ordinary law of supply and demand. By the way, a daily contemporary strongly opposed to the Bill, gives proof of its capability for dealing with the subject, by reporting that the half-litre is equal to "8·3-tenths" of a pint, a jumble that many of those whom it assumes to patronize would be competent to set right.

BRITISH PHARMACEUTICAL CONFERENCE.

The following are amongst the papers promised to be read at the Edinburgh meeting:—

On the Tincture Press. By Mr. C. A. Staples.

On the Compound Mixture of Iron of the British Pharmacopœia. By Mr. C. A. Staples.

On a Method of Obtaining Distilled Water Economically. By Mr. C. A. Staples.

The Composition of the Bottled Mineral Waters of Commerce. By Mr. F. M. Rimmington.

Pharmaceutical Ethics—Apprenticeship. By Mr. S. R. Atkins.

Certain Derivatives from Codeia. By Dr. Wright.

Report on the Purity of the Peroxide and Hydrated Peroxide of Iron of Commerce. By Mr. A. H. Allen.

Report on the Permanganate of Potassium of Pharmacy. By Mr. A. H. Allen.

On Solutions. By Mr. T. B. Groves, F.C.S.

On Linseed. By Mr. Greenish.

Remarks on the Proposed Changes in the Chemical Nomenclature of the Pharmacopœia. By Mr. C. R. C. Tichborne, F.C.S.

Examination of Samples of Commercial Chloral Hydrate. By Mr. M. M. Patteson Muir, F.C.S.

On Crystalline Principles in Aloes. By Professor Dr. F. A. Flückiger.

Notes on Aloes—No. II. By Dr. W. A. Tilden, F.C.S.

Report on the Chloral of Trade. By Mr. A. H. Mason, F.C.S.

Pharmaceutical Notes on *Rhamnus Frangula*, Linn. By Mr. Baildon.

ADAMSON INSTITUTE.

Under this name a memorial will shortly be erected at St. Andrew's to the late John Adamson, M.D., as an acknowledgement of his services to the cause of science, particularly chemistry and natural history, in that ancient university town.

A correspondent of the *Lancet* appeals to the Editor under the following circumstances:—

"Sir,—I am a gentleman by birth and education. For a certain love to science I chose the medical profession. My experience of it was chiefly rural, where the patient and the doctor are brought legitimately together. My fate led me to purchase a practice in London, and, to my surprise I find myself surrounded with all the appliances of trade—coloured bottles, scents, tooth-brushes, small-tooth combs, treacle, etc. The very practice I entered upon was not without some of these adjuncts. I quickly expelled the coloured globes, and cut down the retail to a minimum. But what am I to do in competition on all hands with more showy establishments? Am I rightly informed that the medical men who are engaged in hospitals, dispensaries, etc., without any salaries, to attend the poorest in the land, are themselves obliged to live as respectable professional men, and eschew trade altogether? If so, does it not appear much more reasonable that we who have to attend the middle and upper classes for considerable payment should ourselves be compelled by some law of the colleges and schools to live as gentlemen, and, while we practise a liberal profession, to leave trade to those to whom it properly belongs?

"Any suggestions will be thankfully received by,

"Your bewildered servant,

"Dilemma.

"P.S.—Some of my neighbours label their windows that they make up medicines ordered by other medical men. Is this professional?"

We notice that the Editor of that journal discreetly omits to give any advice or opinion.

The *Lancet*, under the heading "Spectroscopy in the Law Courts," has the following remarks concerning Mr. Stoddart's recent letter to this Journal* upon the subject of the recognition of blood-stains by the spectroscope:—

"Mr. Stoddart . . . asks us to point out some substance giving a spectrum coincident with that of blood. We cannot gratify him by doing so; but, as we said before, the whole subject of the spectra of coloured liquids is not yet sufficiently well explored to admit of the employment of spectroscopy for the decision of a capital charge. We cannot agree with Mr. Stoddart in thinking that the mistake which two of our best spectroscopists made relative to the spectrum of the mythical Jargonium is unconnected with the question of the degree of confidence to be reposed in the indications of spectroscopy. Before we accept a given absorption spectrum as absolute evidence of the presence of blood, we should know that it is safe to trust to absorption spectra; and in Jargonium we have had a practical example of the results of trusting to them."

The *Scotsman* announces that arrangements are being actively proceeded with in a large number of towns in Scotland for celebrating the centenary of Sir Walter Scott. At the approaching festival, deputations will be present from the corporations of several towns in the north of England, the Caledonian Societies in London and Liverpool, and the Speculative Society of the University of Edinburgh, of which Sir Walter Scott was the Secretary. A great number of the nobility and gentry, as well as several ladies and gentlemen distinguished in art, science and literature, have intimated their intention of being present. An elaborate design for a memorial card has been designed by Sir Noel Paton, a copy of which will be presented to every member of the company as a memento of the occasion. The Jedburgh Town Council has appointed a committee to make the necessary arrangements for celebrating the centenary. Also, at a public meeting at Langholme, it was unanimously decided to hold a demonstration in honour of Sir Walter Scott on the 15th of August.

* See Vol. I. p. 1044.

At an interview of several gentlemen interested in the petroleum question with Earl Morley on Monday last, his lordship intimated his intention to reduce the test standard in the Petroleum Bill now before Parliament to 80° F., and to provide that such portion of the Act as relates to the test shall not come into force until February 1, 1872.

The recent case of poisoning by eating Calabar beans, a notice of which will be found in our Journal, leads us to ask the question, how is it that so important a subject as the history and uses of articles of commerce is not taught in schools? If it were, such accidents would be almost unknown. In Germany it forms part of the instruction of boys at school, the great aim being to supply a knowledge of the different substances they will meet with or have to use during life. They thus enter the warehouse or shop with a fair amount of merchant's knowledge. We trust that these object lessons will not be forgotten by school boards.

The Committee of St. Mary's Medical School has decided to establish three Scholarships in Natural Science open to public competition, each of the annual value of £40, and tenable for three years. *Nature* states that the first of these, and an annual exhibition of £20 will be awarded by open competitive examination in September next.

We learn from *Nature* that the Royal Commission on Scientific Instruction and the Advancement of Science has adjourned till November, and that the publication of some of the evidence already taken may shortly be expected.

FIRST OR PRELIMINARY EXAMINATION.

The Questions for the Preliminary Examination on July 3rd were as follows:—

LATIN.

Translate into English two or more of the following sentences:—

1. Quod ubi Cæsar rescivit, quorum per fines ierant, his, uti conquirerent et reducerent, si sibi purgati esse vellent, imperavit: reductos hostium numero habuit; reliquos omnes, obsidibus, armis, perfugis traditis, in deditionem accepit.
2. His rebus cognitis, Cæsar Gallorum animos verbis confirmavit, pollicitusque est sibi eam rem curæ futuram: magnam se habere spem, et beneficio suo et auctoritate abductum, Ariovistum finem injuriis facturum.
3. Hydrargyrum cum confectione tere, donec globuli non amplius conspici possint; deinde, adjectâ glycyrrhizâ, omnia simul contunde, ut fiat massa.
4. Divide in partes duodecim, quarum capiat unam secundâ vel tertiâ quâque horâ, ex cyatho parvo lactis vaccini recentis, absente febre.
5. State the superlative degree of each of the following adjectives:—*bellus*, *deterior*, *meritus*, *novus*, and *superus*.
6. Decline the pronoun substantive *tu*.
7. State the gerunds, supines, present and future participles of the verb *sumo*, to take.
8. What case do verbs of giving and restoring govern? Give one or more examples.
9. What case do the following adverbs of place govern: *nusquam*, *longè*, *quo*? Give examples.

ARITHMETIC.

10. Write down in proper figures the following numbers:—one hundred, thirty-two thousand, two hundred and forty-five.
11. How many miles will a person walk in 63 years, supposing he travels 6 miles each day, and there are 365 days in a year?
12. If 40 acres of grass be mowed by 8 men in 7 days, how many acres can be mowed by 24 men in 28 days?
13. Divide $9\frac{2}{11}$ by $\frac{1}{2}$ of 7.
14. Multiply ·907 by ·0025.

ENGLISH.

15. What does orthography teach?
16. Explain the difference between proper and common nouns, and furnish examples.
17. What does the subjunctive mood express? Exemplify the same.
18. Correct the following:—Luxurious living and pleasure begets a languor and satiety that destroys all enjoyment.—Neither discipline nor precept are so forcible as example.
19. Parse the following:—Among the enemies of friendship may be reckoned suspicion and disgust.
20. Write from 15 to 25 lines upon *one* only of the following subjects:—

A. Worldly prosperity.
B. Sources of happiness.
C. Contentment.

ERRATA.—Page 73, col. 1, line 35, *for* Bowers, Joseph William, *read* Williams, Joseph Bower. *After* Sandy, Frederick William, Strood (line 39), *insert* Jones, James, Carmarthen. Page 74, col. 1, line 17, *for* Landell, *read* Sandell.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The Annual Meeting of this Association was held on Thursday, July 20th; Mr. STODDART, President, in the chair.

After some routine business, the Hon. Secretary, Mr. SCHACHT, read the following Report of the Council:—

"The Council of the Bristol Pharmaceutical Association have great pleasure in presenting to the members their Second Annual Report. The 10th rule of the Association indicates the chief duty of the Council to lie in two directions of work,—1stly. The provision of the best means at their disposal for the systematic teaching of the sciences connected with their calling; and, 2ndly. The keeping alive, by a series of appropriate evening gatherings, the general interest of the members in the prime object of the Association, 'the progress of scientific pharmacy.'

"With regard to the latter portion of these duties, the Council have to report that the past session in no way fell short of the excellence reached by its predecessor. Through the kindness of the President, Mr. Stoddart, Mr. Coomber, Mr. Leipner, Mr. Lant Carpenter, and Dr. Tilden, the monthly evening meetings were rendered highly attractive, and good attendances gave evidence of the estimation in which these gentlemen's efforts were held. They have well earned the gratitude of the entire Association, and have deserved its warmest thanks.

"Had the practical papers from the general body of the members on the occasions set apart for the purpose been a little more numerous, the Council would have had unmixed pleasure in congratulating the Association upon this portion of its operations. Unfortunately they received but very few, and are compelled to refer to the subject in the hope that this deficiency may be made good in future sessions.

"With regard to the other portion of their duties, the Council have to report that their arrangements were the same as were made in the previous year. Full courses of lectures upon each of the two departments of chemistry and of botany were delivered by the respective professors of these sciences, Mr. Coomber and Mr. Leipner, and they were well attended. For the lectures on chemistry twenty-three of our associates entered. Of these, ten went in for the Government examinations in May. In one division of the subject five passed, all in the first class; and in the other division, one passed in the first class and three in the second.

"For the lectures on botany fourteen associates entered. Of these, eight went in for the examinations. In one division of the subject two passed in the first class, and three in the second; and in the other division five passed, all in the second class.

"The names of the successful competitors are as follows:—

"*Inorganic Chemistry.*—Mr. Little (1st class, advanced grade), Mr. Bishop (1st class, ditto), Mr. Tamplin (1st class, ditto), Mr. Samson (1st class, elementary grade), Mr. Bennett (1st class, ditto).

"*Organic Chemistry.*—Mr. Tamplin (2nd class, advanced grade), Mr. Little (1st class, elementary grade), Mr. Bennett (2nd class, ditto), Mr. Samson (2nd class, ditto).

"*Structural and Physiological Botany.*—Mr. Little (1st class, advanced grade), Mr. Bennett (1st class, elementary grade), Mr. Samson (2nd class, ditto), Mr. Bishop (2nd class, ditto), Mr. Tamplin (2nd class, ditto).

"*Systematic and Economic Botany.*—Mr. Little (2nd class, advanced grade), Mr. Tamplin, Mr. Baynham, (equal, 2nd class, elementary grade), Mr. Bennett (2nd class, ditto), Mr. Samson (2nd class, ditto).

"And the winners of the prizes are,—

"*Inorganic Chemistry.*—Advanced Grade:—1. Mr.

Little. 2. Mr. Bishop. Elementary Grade:—1. Mr. Samson. 2. Mr. Bennett.

"*Organic Chemistry.*—Advanced Grade:—Mr. Tamplin. Elementary Grade:—1. Mr. Little. 2. Mr. Bennett.

"*Structural and Physiological Botany.*—Advanced Grade:—Mr. Little. Elementary Grade:—Mr. Bennett.

"*Systematic and Economic Botany.*—Elementary Grade:—Mr. Tamplin, Mr. Baynham, equal.

"It is also with great pleasure the Council find themselves authorized to announce that the Department of Science and Art has selected one of these students, Mr. A. Little, for the honour of a silver medal in testimony of his success at the recent science examinations.

"In the last Annual Report hope was expressed that steps would soon be taken towards laying the foundations of a museum and library. The want of a definite home wherein to commence work has operated as a barrier to any great effort in this direction, but the subject has not escaped the attention of the Council; and now that the migration of the Philosophical Institution is complete, there is a greater probability of some arrangement being arrived at between the executives of the two Associations by which this desirable object may be promoted.

"The Council have once more to record their sense of obligation to the committee of the 'Bristol Museum and Library' for their uniform courtesy in granting them the use of their premises.

"With regard to the finances of the Association, the Council have only to remark that they have endeavoured in every way to preserve the strictest economy, and to expend the slender means at their disposal to the best advantage."

W. B., Bristol; Sugden, Manchester; Tanner, Liverpool; Taplin, London; Thomas, Boston, Lincolnshire; Thompson, Manchester; Thorburn, Bishop Auckland; Tigar, Northampton; Toone, Warminster; Turner, Hexham; Twemlow, London; Utting, Diss; Wall, West Bromwich; Walker, J. D., Carlisle; Walker, J. S., Manchester; Watts, D.Sc., Bowdon; Weir, Merthyr; Welch, Reading; Whitrod, Diss; Williams, J. B., Dudley; Williams, J. O., St. Ives; Wilson, Penrith; Wright, D.Sc., London; Wyley, Coventry.

MEETING OF THE GENERAL MEDICAL COUNCIL.

THE PHARMACOPŒIA COMMITTEE.

At the meeting of the Medical Council on Saturday, July 8th, the following Report of the Pharmacopœia Committee was read:—

"The Pharmacopœia Committee appointed by minute of the Council, July 12, 1869, beg to report that, owing to the pressure of important business during the sessions of the Council last year, no meeting of the Committee was held, and no report was prepared for their consideration by Dr. Redwood.

"The Committee met on the 7th inst., and received a report from Dr. Redwood, on the progress of pharmacy since the date of his last report. Some points of importance in connection with pharmaceutical preparations were discussed, and Dr. Redwood was requested to continue his services. It was also resolved that Dr. Christison, Dr. Quain, and Dr. Aquilla Smith be requested to continue their inquiries as regards additions or other changes in the Pharmacopœia, and that Dr. Redwood be requested, in addition to his duty of reporting on the progress of pharmacy, to investigate, from time to time, the composition of articles in the Pharmacopœia concerning which questions have been raised.

"As the sum of £75 remains as balance in the hands of the Committee, it will be unnecessary to ask the Council to place any further sum at the disposal of the Committee for use during the ensuing year.

"R. Christison, *Chairman.*"

Dr. Christison said the first paragraph stated why no report was presented last year. In fact, there was but little material about which a report could be presented. But during that year and the subsequent year useful information had been derived from various quarters, and the Committee were of opinion that all parties concerned in the Pharmacopœia should now get a stimulus to proceed and look after matters that might occur during the next twelve months. To this, he presumed, there would be no objection. He was happy to say they did not require to come to the Council for any allowance, as there were ample funds at command. There now remained only a debt of £104. 14*s*. The Pharmacopœia had a steady sale, and there was a sufficient number of copies to pay more than the debt. They were not entitled to make any profit from it, but simply wished to reimburse the Council for the outlay.

Dr. Quain seconded the motion.

Dr. A. Smith said that, although a member of the Committee, he was no party to the report. He never saw it until it appeared in the programme. He objected to the words "the Committee met on the 7th inst., and received a report from Dr. Redwood on the progress of pharmacy since the date of his last report." It was not a report "on the progress of pharmacy"; it was a report from Dr. Redwood on discussions which took place at the Pharmaceutical Society upon a communication made by him at the suggestion of the Committee two years ago. There was not a word about the progress of pharmacy; the report was mere waste paper. He should like to see the report state that Dr. Redwood had sent in a report to the Pharmacopœia Committee, and suggested that it should not be worded so as to appear that Dr. Christison, Dr. Quain, and himself recommended themselves for re-election.

Dr. Apjohn thought it would be desirable that the Committee should furnish the Council with a summary of their researches into pharmacy. It would seem that there had been no researches. Looking at the report it was so much waste paper, and tended to nothing except to mislead people who were not conversant with these questions into the opinion that experiments were in progress and researches had been made which would render the new edition a great improvement upon the old. If these researches had been made, and these improvements were ready, they ought to be laid before the Council.

Dr. Quain believed that the Pharmacopœia Committee had performed its duty as efficiently as the Council could wish.

Dr. A. Smith: No; I say, and I said before, that the work has not been done efficiently.

Dr. Quain said their duty was simply to take care that an accurate record of what was done in pharmacy was kept, and they had employed for that purpose the services of the gentleman under whose care and auspices the last Pharmacopœia was constructed, a Pharmacopœia which he need not speak of now that it was admitted to be the greatest success that had yet been accomplished in the form of a Pharmacopœia. They gave Dr. Redwood a very moderate payment, and he devoted himself to securing that the new edition should be as good as the last. He (Dr. Quain) had more faith in the opinion of Dr. Redwood than in that of either of the two gentlemen who had just addressed the Council. (Order, order.) He had more confidence in that gentleman's opinion than in that of either of the gentlemen with regard to the construction of a Pharmacopœia. (Hear, hear.) The Committee relied on Dr. Redwood to exercise careful vigilance over the progress of pharmacy, and whenever a new edition was required the new materials would be ready.

Dr. Smith said he did not insinuate one word against Dr. Redwood. He had the highest opinion of him, and was willing to admit his efficiency in every respect. He simply said it was not a report on the progress of pharmacy, and he would repeat the assertion.

Sir D. Corrigan suggested that in the next edition, after each article, its degree of solubility in water should be inserted. At present it was simply stated whether it was soluble, and not the degree of its solubility.

Dr. Christison said he had more reliance in Dr. Redwood than in Drs. Smith, Apjohn, Quain, and himself.

Dr. Apjohn said, that being the case, he would propose that the Pharmacopœia Committee should cease to exist, and that the preparation of the materials for the new Pharmacopœia should be confided to Dr. Redwood.

The President pointed out that the motion could come on when the Committee was to be reappointed.

The Report of the Pharmacopœia Committee was then adopted by the Council.

Dr. Bennett moved, "That the Pharmacopœia Committee of last year, consisting of Dr. Christison, Dr. Quain, Dr. Sharpey, and Dr. A. Smith, be reappointed."

Dr. Parkes seconded the motion.

Dr. Apjohn moved, as an amendment, "That the Pharmacopœia Committee be not reappointed, but that the task of collecting information preparatory to the publication of the new edition of the Pharmacopœia be entrusted to Dr. Redwood."

The amendment was not seconded. Dr. Bennett's motion was then agreed to.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Metric Weights and Measures Bill.—*July 26th.*—Mr. J. B. Smith, in moving the second reading of this Bill, stated that it was founded on the report of a Select Committee, which had ascertained that there were ten different systems of weights and measures in use in the kingdom, and recommended that all those systems should be abolished and a universal decimal or metrical system introduced. The recommendation was as old as Magna Charta, which declared that only one standard of weight and of measure should be used throughout the country, and now, at the end of 700 years, he asked the House of Commons to recognize the recommendation by a Bill. The necessity for some measure of the kind became painfully obvious at the Exhibition of 1851 and subsequent exhibitions, where manufacturers from different countries exhibited their goods, but could give to strangers no proper idea of their price, in consequence of the diversity of weights and measures. The treaty of commerce with France still further disclosed the inconvenience of the present system, and a committee of that House was accordingly appointed to take the question into consideration. That committee reported that we had 10 different systems of weights and measures, 19 different measures of land, 61 measures for selling wheat, 13 measures for selling oats, 16 measures for selling barley, and 9 for selling butter, and 4 measures for selling flour. In 1864 a Bill was brought in for the establishment of the metrical system; that Bill was opposed by the Government of the day, but they were defeated, and Government promised that if the Bill was turned into a permissive Bill they would take it in hand. But although it was legal to use metric weights and measures, if they were found in a person's possession that person was liable to be prosecuted. Professor De Morgan, in his evidence before the committee, said, "I cannot put in language the advantage to the people of using the same measure." The extreme simplicity of the metric system and the ease with which it was acquired had gradually recommended it to the world, and it was now used compulsorily in France, Belgium, Greece, Spain, Portugal, Porto Rico, Italy, Roumania, Switzerland, Chili, Brazil, Mexico, the Argentine Confederation, Peru, etc., and on the 1st of January next it would come into operation throughout all the States of Germany. There were 200 millions using this system compulsorily and 200 millions more were using it permissively. Of the exports from this country only 25 per cent. were exported to countries using English weights and measures, and 66 per cent. were exported to countries using metric weights and measures. The introduction of the system would have also an important bearing on education, from the ease with which it was acquired. After stating that the Bill had the support of the Chambers of Commerce and various other influential societies throughout the kingdom, Mr. Smith continued, he understood that the Board of Trade would oppose this Bill, and no doubt they would be told that it was a difficult question to deal with, and that its adoption would give rise to serious inconvenience. No doubt there would be very considerable inconvenience. But he must most distinctly say that they did not want a permissive Bill, because in no country could such a change in the law be enforced unless the measure were compulsory. We had for long had an imperial bushel, and yet there were other local bushels used throughout the kingdom. Mr. Cobden, in his last speech upon the subject, spoke strongly in favour of the French system as compared with our own; and his authority ought to be much relied on. What the advocates of this measure asked for was simply that there should be one system of weights and measures throughout the land; and what they looked forward to was the time when there should be one system only of weights and measures throughout the world.

Mr. B. Hope moved that the Bill be read a second time that day six months. He also desired to see one system of weights and measures throughout the land; but it was the English system, and not the French system, that he desired to see adopted. The system which this Bill proposed to introduce would lead to very serious inconveniences. The metric system was good for multiplication, but it failed in division, especially in the natural division of halving and quartering. He was assured on very high authority that in Holland, though the new system had been introduced, the old practice still prevailed. The Standard Commission recommended that the metric system, if adopted, should be permissive and not compulsory; that any Bill to make it permissive should be brought in by the Government, and that it should deal widely with the question as a whole; but the Bill flew in the face of every one of those recommendations. If such a measure became law, it would necessitate the whole country going to school again upon the most elementary ideas of material life; it would throw all leases and engagements into confusion; it would puzzle farmers north, east, south and west with ares, metres, and kilometres, and their decimal parts; it would give dishonest traders increased facilities for cheating their customers, and it would cause infinite misery and inconvenience to all the poorer classes of our fellow-creatures. Sir J. Herschel, in a letter to himself (Mr. B. Hope), in 1868, said,—"As respects a reference of our fundamental units to a natural standard, our national system is anything but the haphazard, indefensible thing it is usually represented to be. The polar axis of the earth is a much better natural unit than the quadrant of a meridian through Paris, and, dividing this into 500 million inches, our actual imperial foot comes within a thousandth part of twelve such inches, or a geometrical foot. I have by me two foot-rules, one by a good optician, the other purchased at a good shop, and none the worse for wear, which differ from each other by more than that quantity. Taking for the definition of our ounce the weight in air of 1-1000th part of such a geometrical cubic foot of distilled water at 62° F. (our standard temperature), according to the rate declared in the 5th Act of George IV., our actual imperial ounce differs from such a geometrical ounce by only 1-7000th part. But if, as some later experiments seem to have shown, that rate is slightly incorrect, then according to these experiments (that is, according to the best of our actual knowledge) the weight of that bulk of water *in vacuo*, at a temperature of 72° in place of 62°, is with absolute precision identical with our actual imperial ounce, also weighed *in vacuo*. As for our measures of capacity, our half-pint is the measure of ten ounces of water."

Mr. Stevenson, in seconding the amendment, pointed out that there was only one pint, one pound, and one yard throughout the whole of the United Kingdom, throughout the United States of America, and wherever the English language was spoken; and they were told that notwithstanding that the metric system had been forced into operation in France by the power of a centralized Government, the foot-rule divided into twelve inches was still of frequent use in the workshops there.

Sir C. Adderley said that the question was whether the disadvantage of getting rid of the old system would more than compensate for the advantages attending the adoption of the new one. He was of opinion that although it might give a new language to commerce, it would be of inestimable advantage to the country to adopt the metric system. It had already been adopted in the colonies, and by Canada in particular, and what could be done by our colonies could certainly be done here. He denied that the metric system had broken down; but even if it had, it did not touch the main question, whether the commerce of England did not demand a simple and intelligible language common to all the nations with whom we traded. Surely, if the commerce of the world demanded a world-wide language, England should not be the country to stand in the way. There were two points chiefly affected, namely, the home trade and the commerce of the world. In this country a stone meant a different weight in respect to almost every different description of article, and a hundred-weight meant 112 lbs., 120 lbs., 128 lbs., and even 140 lbs., in different localities, and according as it was used with respect to different commodities. In his own district, a bushel meant thirty-two different measures. Then with regard to general commerce, was it of no importance to England to use the language of commerce adopted by all the other nations of the world? The French system was as near perfect as any one could be, and it had been generally adopted, though he admitted that a philosopher like Sir J. Herschel objected that the metre was not the best form of unit.

Mr. C. Fortescue said that it was impossible to expect that any legislation could take place on the question this session. The real question was whether there should be a compulsory or permissive measure. In his opinion they had not yet attained that state of things which the Committee contemplated as a condition of legalizing the metric system—namely, the sanction and conviction of the public. The examples of France and of British India would not justify a hasty decision; the evils which formerly existed there having been far more intolerable. It would be the duty of the Government to make some general proposal on that subject next session, including the introduction of the metric system, and the whole of the recommendations of the Royal Commission would be taken into account. Under the circumstances he would put it to the hon. gentleman whether it was desirable to ask the House to commit itself at once to the adoption of the metric system.

Mr. Scourfield said that although the decimal system afforded a good basis for rough division, for minute calculations the duodecimal system was preferable.

Mr. Baynes said the metric system was not, as had been alleged, difficult to learn; if they had a black board there, and the metric system were illustrated upon it, all the opponents in that House would, he believed, at once rise up converts.

Mr. C. S. Read said, as an agriculturist, he felt it was absolutely necessary that there should be a better system of weights and measures, and he believed that on the whole the metric system would be the best. He had sold beef by the cwt., mutton by the lb., and pork by the score. In Shropshire there were not only different weights in different towns, but different weights on different market days in the same town.

Alderman W. Lawrence said he did not think the advantages to be derived from the metric system would counterbalance the expense, trouble, and inconvenience which must arise from such a change. What chance would there be of carrying out the decimal system on the basis of the imperial bushel? Had his hon. friend taken into account the cost to the nation of new weights and measures in every shape throughout the country? Under the metric system the effect of the substitution of the litre for the pint would be that the working man would get 87-100ths of a pint of beer instead of a pint.

Mr. Henley thought that a question of that vast importance ought to be in the hands of the Government. The hon. member for Norfolk said that agriculturists wanted uniform weights and measures. Then why on earth did they not have them? He supposed that like many other men they preferred doing as they pleased. As regarded dealings of masters and labourers under the metric system, it would be almost impossible for the latter not to conceive they were wronged. He believed that the cost of new weights and measures would amount in the first year to a tax of £3,000,000.

Mr. Fothergill thought the difficulties of the metric system among the working classes would be almost insurmountable. He knew thousands of colliers in his own district, and that remark especially applied to them. The introduction of the proposed system of weights and measures would entail upon the employers and manufacturers, very great expense in the purchase of new machinery. He was quite sure that both the working men and the employers of labour on a large scale would strongly object to the introduction of the metric system into this country.

Mr. Pell supported the Bill. The strongest argument urged against the measure was that the introduction of any new system of weights and measures would lead to a vast amount of inconvenience; but already there was a tendency in the country to adopt the decimal system in the measure of land and corn; and he maintained that the balance of convenience was on the side of those who supported, and not upon the side of those who opposed this measure.

Colonel Sykes supported the Bill.

Mr. Illingworth said it seemed to be generally admitted that the metric system possessed great advantages over that at present in use in this country; but it was thought that a compulsory change suddenly made would be productive of considerable inconvenience to the humbler classes. Once let it be known throughout the country that the system would be enacted compulsorily, and would come into force in the course of ten years from the present time, and the school boards would make arrangements for teaching it; and thus in a very short time the minds of the children would become familiarized with the new and improved system.

The House then divided—

For the second reading	77
Against it	82—5

The Bill was therefore rejected, the announcement of the numbers being received with cheers and counter-cheers.

Attempted Suicide by Laudanum.

On Friday, July 21, William Johnson, a pensioned soldier, was charged at Marlborough Street Police Court with attempting to commit suicide. He was found by a policeman lying in Kensington Gardens, with some phials and a bottle by his side, all of which had contained laudanum, purchased at different shops. The prisoner told the magistrate that he had been twenty-one years in the army. He was a German, and could speak French and German, so thinking he might do better, he did not renew his service, but being unsuccessful, he grew despondent and took some laudanum. The magistrate remanded him.

Conviction of a "Medical Botanist."

On Friday, July 14, Charles de Baddeley, herbalist, and Sarah de Baddeley, his wife, were indicted at the Central Criminal Court, for unlawfully supplying a certain noxious drug—namely, ergot of rye—knowing that it was intended to procure abortion.

The evidence in this case has already been reported (Vol. I. p. 1041). It was urged on behalf of the prisoners that no offence had been committed, and some strong observations were made as to the conduct of the police in laying the trap by which they had been caught.

The jury found the prisoners guilty, and they were each sentenced to twelve months' hard labour.

Poisoning by a Soothing Cordial.

An inquest was held at Silkstone Common, on Saturday last, on the body of a child who had been poisoned by a soothing cordial under the circumstances reported last week (p. 77). The jury returned a verdict that the poisoning was accidental.

The Alleged Poisoning Case at Cambridge.

The prisoner in this case is again remanded, Dr. Letheby having reported that he does not find any poison in the portions of the body forwarded to him. A telegram has been sent to Professor Liveing, requesting him to be present at the next examination, to give evidence as to the circumstances under which he detected the presence of arsenic.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

VACANCIES.

Assistant-Dispensers in charge of Medical Stores at four of her Majesty's Naval Hospitals. Candidates must possess the Major qualification of the Pharmaceutical Society, and be not less than twenty or more than twenty-five years of age. Applications to be addressed to the Director-General of the Medical Department of the Navy, Somerset House, W. C.

APPOINTMENT.

Mr. Robert Rogers, M.P.S., has been appointed Dispenser to the Plymouth Public Dispensary, in the room of Mr. W. J. Dicker, who held the office for thirty-three years.

Correspondence.

**** No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Pharmacy Bill.

Sir,—Until the last number of the Pharmaceutical Journal appeared I had allowed myself to hope that, upon the abstract question of legislative interference with the internal arrangements of our shops, all chemists were of one mind. I thought that one and all alike deprecated such legislation, believing each individual member of their fraternity to be competent to frame all requisite precautions for the safety of the public and the security of his own means of living, without the intervention of any law upon the matter. I imagined the difference of opinion which existed amongst us to consist mainly in this—that whereas *some* thought that an opposite opinion being held by the public and the Privy Council, and the power of the latter being irresistible, it behoved us to yield the principle, and to accept the best terms we could get; *others*, on the contrary, considered that the public was simply misinformed, that the contemplated intrusion of the Privy Council was capable of being resisted, and that the principle of business independence was worth fighting for.

In ranging myself, therefore, with those who proceeded to resist the action of the Privy Council, I believed, not only that I was helping to do battle for the honour of the whole trade, but that if we in any way succeeded in our object the whole trade would rejoice.

To a very considerable extent we did succeed, for the Bill was withdrawn "with the general approval of the House," and there is every probability that, had the whole trade been united in principle (as I had thought was the case), it would have died the death it deserved. At any rate it was withdrawn, and I looked for a general expression of content. But the last Journal contained a letter and a document singularly the reverse of what I had hoped to see.

In the first place, I am thereby proved to have been quite wrong in supposing we had the secret sympathy of our professed opponents, for we now find that all the efforts we were making to enlighten our parliamentary representatives, and to persuade them to treat us with some respect, were at the same moment being thwarted by a circular, signed by some of the best-known names in the trade, which kissed the hands of the framers of the Bill, and begged hon. members to pass it into law. This was no very pleasant discovery; but the revelation displays something more—for the publication of this circular, with the names appended, *a week after the withdrawal of the Bill*, leads to the almost necessary inference that these gentlemen intend for the future openly to advocate the very principle against which we have been struggling. They no longer affect to be trying to make the best of a bad job, but they join issue with us on the principle itself, and assert that the job is a good job; to quote their own words, "they presume to point out how completely the objections to the Bill have been removed (by the amendments) and trust hon. members will support it accordingly."

I am grieved beyond measure at the course taken by Mr. Sandford and his friends (I am taking for granted that he had their consent to publish the document as he has done), inasmuch as the elevation of such a standard within the ranks of our own body cannot but be regarded by many of us as sheer treason, and must create a ground of division emphatic in proportion to the emotions such a word is likely to arouse.

G. F. Schacht.

Clifton, July 24th, 1871.

Sir,—I take leave to recommend your correspondents not to fan the expiring embers of the poison regulations; leave them alone and depend upon it these will soon go out. Weigh the pretensions of Dr. Simon in the scale with the powerful influence which the chemists throughout the land have commanded in Parliament, by reason of the fairness and justice of their cause, and those pretensions will be found as dust in the balance. The few who feel they cannot conduct their business with security to themselves and safety to the public without being bound in a Parliamentary strait-jacket, I earnestly urge at once to consult Dr. Munro.

Kilburn, July 24th. John Beaton.

Sir,—You properly deprecate a continuance of the recent conflict of opinion on the Pharmacy Bill, and every true friend of the Society will re-echo your sentiments; you speak, however, with bated breath, feeling, probably, that the circular of Mr. Sandford would be promptly repudiated. As President of the Hull Chemists' Association, it is within my knowledge that the circular has caused a strong feeling of dissatisfaction,—the general impression here being that any man who could deliberately append his name to such a document, understands very little of the principles for which we in the provinces so determinately struggled. In my judgment the parts of the Bill eliminated were as small dust in the balance, compared with the real and weighty grievances which remained. The opening sentence of this strange circular states, that "in 1868 the Society had to resist as strongly as possible the introduction of restrictive clauses, which would have seriously fettered chemists in their daily avocations;" and it winds up with the following, in italics:—"We have presumed to point out to you how completely the objections to the Bill have been removed, and trust you will support it accordingly." Who could suppose that the Bill, of which the signatories speak so complacently and which they are so anxious to embrace, is still partial in its operation—omitting surgeons, hospitals, dispensaries, etc.—and contains compulsory, penal and disqualifying clauses; surely the force of inconsistency can no further go! We shall continue to struggle against harsh and uncalled-for legislation, whether Parliamentary or Pharmaceutical, and I am satisfied we shall have not only the trade, but the public with us. I will only add that the effect of the circular in Hull has been to determine us to organize an association, including East and North Yorkshire and North Lincolnshire, the object of which will be, "the protection of the public against the risk arising from compulsory fancy regulations and the defence of the trade against penal and restrictive enactments, until at least a *primâ facie* case for legislation has been established."

Upon those, who by their acts are provoking the renewal of a fruitless contest, must rest the responsibility for the misapplied time, energy and money which might otherwise have been devoted to Pharmaceutical education.

Hull, July 25th, 1871. James Baynes.

Sir,—The success of the opposition to the passing of the late Pharmacy Bill is not likely to leave in a captious mood those who have so much reason to be satisfied at its withdrawal.

At the same time, they will not affect to underrate the importance of the Circular, bearing the signatures of a number of chemists, which you published last week. As Mr. Sandford writes you that he was the recipient of the signatures given to this circular, there can be no impropriety in treating its construction and mode of issue as being Mr. Sandford's. The other gentlemen attaching their names have, of course, become responsible for the document; but it is evident that the motives influencing them individually must have been widely various.

To place such a document in the hands of members of Parliament upon the day of the second reading was, doubtless, considered a clever piece of strategy, since the circular dishonestly (I speak advisedly) assumes that its promoters were persons who recognized the faults of the original Bill, and who stated the pith of their document in the following words,—"to point out to you how completely the objections to the Bill have been removed." What are we think of persons who could use such language, when their every previous public word and act had been to defend the original Bill as having no faults? However, the treacherous arrow missed its mark by the withdrawal of the Bill, and it now affixes to public gaze many names which chemists throughout the kingdom see there with sorrow.

The plain fact is, that Mr. Sandford has set up a new Cave of Adullam. The promised prospect of a settlement of a vexatious question brought most of its occupants, and from a mass of indifferentism he has had considerable success. The dramatic effect of using the names of firms as signatories was also cleverly planned; but as regards certain "historic houses," those having the legal right to the names of some who were defenders of the liberties of chemists, appear to have little regard for the principles held by their predecessors.

We now ask, Why did Mr. Sandford gather together the names of 120 chemists to offer their opinions? Were they representatives of their brethren, or authorized to speak for them? Certainly not. The feeling of the country had been expressed in every possible way, through votes of annual meetings, of the Council, through a deputation to the Vice-President of the Privy Council, through three Defence Associations, through trade meetings in a dozen of the chief towns, and through petitions signed with unprecedented unanimity. Since one alone of the Defence Associations numbers more than 500 members, it does not seem very likely that Mr. Sandford's new party can successfully compete in the representation of popular feeling.

The late circular will not fail to have one result,—in consolidating and making permanent the various Defence Associations. It is a direct challenge from Mr. Sandford on behalf of personal government to that system of representative government by which the Pharmaceutical Society is regulated. Such a contest will draw sharp lines, and those who have wished to trim their sails to every wind will fall out of the race. Submission to what has practically been personal government has already cost our body dearly in the late expenditure of time, energy, and money, which has been a consequence of Mr. Sandford's want of knowledge of his brethren in 1868. The alliance between Mr. Sandford and his constituency stands on a strange footing, when he puts aside its most plainly expressed will, as soon as it differs from his own, and seeks by most questionable means, and equally questionable allies, to enforce his wishes.

It is to be noted that the consideration already given to the subject by many members of the House of Commons has had most satisfactory results. So acute a reasoner as Mr. W. M. Torrens, M.P., accepts the question as involving most important constitutional rights, and is determined in this favourable position to withstand the dangerous encroachments of bureaucracy. The Bill is spoken of as being "the most unpopular of any since the present Parliament was called."

Legal M.P.'s rapidly perceive the fallacies which have been woven to cover the natural repulsiveness of the measure. "Very sharp practice" was the verdict of one as to the pretended contract made in 1868; whilst another sententiously disposed of the whole question by the remark, "Another piece of over-legislation."

Those who appealed to members of the House of Commons are not likely to stultify themselves by letting future judgment of the question go by default. They have received from the Right Hon. W. E. Forster and the Government concessions which the Medical Officer of the Privy Council and Mr. Sandford had refused them; and in the giving up of the absurd "poison bottle" they have a reward that repays many labours.

But, if another attempt should be made to pass a similar Bill (it ought to be intituled "A Bill to save the feelings of two men at the expense of ten thousand"), those who opposed the Bill of 1871 will once more—not "with light hearts," but with undaunted ones—appeal, and not in vain, to that greatest of representative bodies, the British House of Commons.

Leeds, July 25th, 1871. RICHARD REYNOLDS.

Sir,—In "a letter addressed to members of Parliament" we have a forcible illustration of how consistency, at one time a virtue, may degenerate into vice. In 1868, when the Society delighted to honour an individual member of the Council, it was in consequence of his strong resistance to restrictions being introduced into the Pharmacy Act, which would have seriously fettered chemists in their daily avocations. It was also from implicit confidence in his representative capacity that he was permitted to act almost absolutely with the Government and the officials of the Privy Council, and to arrange that tacit understanding which was the means of passing the Bill, but of which the Society knew nothing.

Consistency has since compelled him to enforce the part he had guaranteed the Society should perform. Consistency caused him to resign his exalted position, rather than surrender the views he entertained as imperative on the part of the Society to carry out, and for this personal sacrifice he was extolled, and general approbation given for his conscientious observance of that which to him was a point of honour and a duty.

Up to that period few there were who denied that his consistency was a virtue, but since then the scene has entirely changed. Still bearing the esteem of his fellows as a gentleman and a man of courage and honourable convictions, he was no longer deputed to act as the exponent of the trade's desires, but became voluntarily its antagonist. By the result of the elections he was no longer compelled to enforce the principles as a private individual that he had undertaken as the representative head of an approving Council. By the elections it was proved that he did not represent the true feeling of the trade; and although his letter addressed to members of Parliament bears the signatures of many esteemed names and firms of good pharmaceutical standing, they simply show a sympathy for the writer of the letter, rather than of the sentiments it contains, inasmuch as the majority had already pledged themselves to the opposite side, and signed petitions against any interference whatever. The inference intended to be impressed upon members of Parliament was scarcely as fair as could be desired, inasmuch as there are represented 65 towns, containing 783 members, and out of that number 715 had protested against the Bill, and signed petitions in opposition to it. And yet, by obtaining the signatures of 56 local secretaries of the Society, the feeling of the majority is ignored, and a false impression conveyed. It is quite clear that these local secretaries have been caught napping, or else they acknowledge themselves the officials of Mr. Sandford, and not of the members of their locality or the Society they are elected to represent. In glancing over the London signatures, names of those may be observed who formerly declared education to be the only safeguard, and who protested against any check that did not emanate from the brain. Are the commanding premises in Bloomsbury to be put up to auction in consequence of our educational system having proved ineffective as regards the training of pharmacists, or the consequent safety of the public? Or is it considered a sufficient compensation to these gentlemen that every surgeon and others keeping open shop should be marked incapable of arranging their own bottles?

The question has lost its broad character and become a personal matter. In 1868 certain conditions were advanced to which the trade was not a consenting party, and which it has since unequivocally condemned; and yet notwithstanding five-sixths of the trade had declared its distinct opposition, for personal considerations we were called upon to fetter ourselves and assist in like manner to manacle the members of a learned profession.

It cannot be denied that those who are aiding the Privy Council to subject us to its control, are but an insignificant minority, as far as numbers tell. They cannot deny that in exercising their own judgment, they are forcing upon others restrictions repugnant to them and totally uncalled for, and are exhibiting more the spirit of pique than a desire to serve the trade. They are enabling those who made promises to the Government to retaliate in consequence of the disappointment that has fallen upon them by the rejection of their leadership. Is it not sufficient for those who are enamoured of the regulations to adopt them, without compelling others who have arrangements of their own, which they consider better and more appropriate?

If the shelving of the Bill this year is but the prelude to its reproduction next Session, it is to be hoped that a better spirit will prevail, and that those who have gone beyond the bounds of consistency to fetter the trade, will respect the decision of the majority and put aside all personal feeling and obligations other than those which belong to them as members of the chemist and druggist fraternity.

July 25th, 1871. JOHN WADE.

Sir,—The array of influential names appended to a circular, asking members of Parliament to support a Bill to authorize the inspection of pharmacies, with the consequent power of summoning before magistrates and inflicting fines, suggests the question,—when will chemists realize their improved and improving position, and indulge in a little justifiable self-respect?

It is probable nine-tenths of the chemists on the register would willingly adopt the simple regulations recommended by the Council; and there can be no doubt that not one-tenth would willingly submit to the degradation of compulsory inspection. I would suggest a counter-representation to the members of the House of Commons, stating that the subscribers thereto, although willing, and thereby pledging themselves, to adopt the "recommendations," protest, in the strongest possible manner, against their voluntary and successful efforts to make themselves worthy of public confidence being dishonoured and suspected.

Chemists, by much labour and self-sacrifice, have placed themselves above the condition which could alone justify inspection. Why should Parliament be asked to deal with them as if they had done nothing, and to treat their self-elevation as a punishable offence?

Glastonbury, July 25th, 1871. T. MAYHEW.

Sir,—I am not a little surprised at the manifesto you publish from the pro-regulationists. I confess I feel somewhat at a loss to account both for its existence and for its appearance after the withdrawal of the Bill. That the minority should seek by a movement in ambush to get an advantage over the majority, is an act not so graceful as we should have expected from the great names connected with it.

The inherent errors and evident want of consideration observable in the circular, mark it as one of the mistakes so often committed in haste to be repented of at leisure.

But why is it published? A mistake of that kind should be only grieved over and forgotten. Then why is it published? Can it be an open declaration of war? If so, it would appear that the right hand of the pro-regulationists has forgotten its cunning. But whatever be the character of the proceeding, it is evident that we must keep in working order the organization which was necessitated by the indifference previously shown by a majority of the Council to the opinions of a majority of the Society.

It may be that a reform in the government, if not a revolution in the constitution of our Society, will spring from the continued disposition of a section (an influential section, I am willing to admit) of metropolitan pharmacists to oppose the general body of the trade upon political questions.

BARNARD PROCTOR.

Grey Street, Newcastle, July 26th, 1871.

Sir,—May I beg the favour of your inserting the following correspondence in the next number of your Journal?

171, *High Holborn*, JOHN CARR.
July 22nd, 1871.

63, *Piccadilly, Manchester*,
July 21st, 1871.

Sir,—I think it is fair to you, as well as just to the Association I represent, to inform you that I have been repeatedly questioned, and an explanation has been frequently sought from me, to account for the strange inconsistency in your voting since your election to the Pharmaceutical Council.

In your letter of the 14th of March you consent to be nominated as a candidate by the "Chemists' Defence Association;" you likewise approve of its object, and offer to subscribe to its funds. In consequence of this agreement of opinion, you were nominated, and your election to the Pharmaceutical Council was duly secured. Notwithstanding this honourable and definite arrangement, you have on every occasion recorded your vote in favour of compulsory poison regulations, and against the Society taking any part in preventing the 'Amended Pharmacy Bill' becoming law.

If you have changed your views, and are now convinced that compulsory poison regulations are necessary, it is only equitable that you should resign your seat, as you were returned to the Council for the specific purpose of opposing such unjust and unnecessary restrictions.

Please to consider this correspondence as subject to publication. Awaiting your reply,

I am, Sir, your obedient servant,
ROBERT HAMPSON, *Hon. Sec.*

JOHN CARR, Esq.

(REPLY.)

171, *High Holborn, London*,
July 22nd, 1871.

Sir,—In reply to your letter of the 21st instant, I beg to decline any explanation of my votes at the Council-table of the Pharmaceutical Society. I sit at that board to exercise and act according to my judgment and the best interests of the Society.

You say I must consider our correspondence as subject to publication, and I have therefore no hesitation in informing you that I shall myself publish it in the next issue of the PHARMACEUTICAL JOURNAL.

I remain, Sir, yours truly,
JOHN CARR.

To R. HAMPSON, Esq.

In addition to the foregoing correspondence, the following has been forwarded to us by Mr. Hampson:—

63, *Piccadilly, Manchester, July 24th*, 1871.

Sir,—Your reply of July 22nd is duly to hand. I certainly expected some explanation to account for the breaking of the pledge given in your letter accepting the nomination, but I will not lengthen this correspondence by any further comment. I am content to leave the facts as revealed in these letters to the verdict of honourable men.

I am, Sir, your obedient servant,
ROBERT HAMPSON, *Hon. Sec.*

P.S. I have, this morning, sent the whole of the correspondence for publication in the next issue of the PHARM. JOURN.

London, 171, *High Holborn, March 14th*, 1871.

Sir,—In reply to your letter, I beg to say I shall have no objection to be nominated as a candidate at the next election of members for the Pharmaceutical Council, by the Defence Association. I entirely agree with them in resisting the unjust and unnecessary restrictions the majority of the Council are anxious to place upon us, and should have joined you, but, as a member of Council, think it better to be quiet for the present; at all events, if it is requisite, I shall be happy to subscribe to the objects of the Society.

I may mention I have nominated Mr. E. Smith, of Torquay; he is an intelligent person, and would make a most useful member of Council; he has promised to serve, if elected, and is totally opposed to the majority of the Council on this matter; he has taken great interest in the question, and has published one or two papers on the Storage of Poisons in the Journal.

I remain, dear Sir, yours truly,
JOHN CARR.

ROBERT HAMPSON,
Hon. Sec. to the Chemists' Defence Association.

Sir,—May I request the favour of your inserting the enclosed correspondence in the forthcoming number of the Journal?

Perhaps I may be allowed to state that I have not previously had any correspondence, either directly or indirectly, with the Chemists' Defence Association.

July 25th, 1871. EDWARD SMITH.

(COPY.)

The Chemists' Defence Association,
63, *Piccadilly, Manchester, July 21st*, 1871.

Sir,—The members of the "Chemists' Defence Association," and those generally who have opposed the enactment of further compulsory poison regulations, have expressed much surprise, and some indignation, at the support you have given to the members on the Pharmaceutical Council who are in favour of further legislative enactments of a restrictive character.

The following is a quotation from a letter received by me from Mr. Carr, dated March 14, 1871:—

"I may mention I have nominated Mr. E. Smith, of Torquay; he has promised to serve if elected, and is wholly opposed to the majority of the Council on this matter; he has taken great interest in the question, and has published one or two papers on the storage of poisons in the Journal."

In consequence of this definite guarantee of Mr. Carr's, your name was with perfect confidence included in the list of candidates put forward by the Chemists' Defence Association, and without a doubt your election was secured thereby.

As I presume that you have changed your views on the question at issue, I do not see how you can consistently, or in common fairness, continue to occupy your seat at the Council, knowing as you do, that you were returned to support views directly opposed to those you now entertain.

Please to consider this correspondence subject to publication. Awaiting your reply,

I am, Sir, your obedient servant,
E. SMITH, Esq. ROBERT HAMPSON, *Hon. Sec.*

(COPY.)

Torquay, July 22nd, 1871.

Sir,—I have to acknowledge the receipt of your communication of yesterday's date, somewhat imperiously, on behalf of your Association, calling upon me to resign my seat at the

Council of the Pharmaceutical Society, and further erroneously attributing to me a change of opinion respecting the Poison Regulations.

As I am not a delegate of your Association, nor in any way connected therewith, I shall not enter into any correspondence respecting the matters referred to in your note, but must content myself now by distinctly repudiating the authority your Association presumes thus to assume over members of the Council of the Pharmaceutical Society.

I am quite ready and most willing at any time to reply to any gentleman, who courteously communicates with me, on the subjects referred to in your note.

Yours,

R. Hampson, Esq. Edward Smith.
Hon. Sec. Defence Association.

The Council of the North British Branch of the Pharmaceutical Society and the Pharmacy Bill.

Sir,—In the hope that the question of poison regulations and the late Pharmacy Bill have sunk into oblivion to rise no more, and being desirous that differences of opinion upon them should now be cemented, especially at the prospect of a pleasant "Conference" meeting in Edinburgh next week,—I would have preferred to let the matter rest in peace, but I consider that a word of explanation is necessary regarding the report of a meeting of the Council of the North British Branch of the Pharmaceutical Society published in last Saturday's Journal.*

The high-sounding title, "The Council of the North British Branch of the Pharmaceutical Society," will, doubtless, be looked upon by our friends south of the Tweed, as a representation of the members of the Society in Scotland, and, consequently, that the decision of that body on the Amended Pharmacy Bill will be representative of their opinions. I have reason to know, and I believe I am quite justified in stating, that the present Council is not a *fair* representation of the North British members of the Pharmaceutical Society. Their decision, therefore, cannot in any case be accepted as expressive of the feelings of the members the Society in Scotland. This, of course, opens up the question, "How is this Council elected and the Society conducted?" I trust it will be discussed on some future occasion; meantime I will content myself by stating that I have refrained from sending reports to the Journal of the action taken by the "West of Scotland Chemists' Defence Association" against this Bill in all its forms, as I consider the columns of the Journal of late have been occupied more than was necessary with this uncalled-for poison question, and much to the detriment of matters of greater importance to the Society, which I look upon as purely an educational institution.

James M. Fairlie.
St. George's Cross, Glasgow, July 25th.

Informal Petitions.

Sir,—That numerous petitions have been rejected on the ground of informality, is apparent by reference to the enclosed printed form:—

(Copy.)

House of Commons.

Journal Office.

Sir,—With reference to the accompanying Petition, I have to call your attention to the Standing Order of the House, which requires that every Petition must contain a Prayer.

There is no Prayer to the sheet upon which this Petition is written; it is, therefore, informal, and will not be submitted to the Select Committee on Public Petitions.

The words, "Your Petitioners will ever pray, etc.," have no reference to the subject-matter of the Petition.

I have the honour to be, Sir,
Your obedient servant,
Wm. Glynn.
Petition Department, Journal Office, House of Commons.

Now, although our petition was read over at least a hundred times during the day and a half we had for obtaining signatures,—was approved by our solicitor, and by our member of Parliament, no one detected the omission of the few words that constitute its ineligibility.

The comment of Mr. Peek is, however, noteworthy, who in returning the petition, says,—

"The Bill having been withdrawn is a matter of no consequence, but another time the necessary formality must not be forgotten." Allow me, Sir, to add, in conclusion, my humble opinion that the most effective and constitutional way of moving any Government, is the expression of public opinion, thus saving a vast amount of circumlocution, writing, printing, interviewing, deputation and expense of postage, travelling, etc.; above all, of brain-power that might have been more profitably directed.

R. Goodwin Mumbray.
Richmond Hill, July 26th, 1871.

Poisoning with Beans at Liverpool.

Sir,—I enclose three "beans," apparently of different species, the names of which I cannot at present learn. Perhaps you can identify them, and kindly let me know the result through the Journal. I obtained these from Mr. Smith, of Athol Street, the gentleman to whose shop the sufferers from Calabar bean poisoning were taken the other day. I was there told that beans similar to the sample were along with the Calabar-beans, and were as freely partaken of as the others. I am also inclined to think that castor-oil beans were present, as I became acquainted, about the same time, with a case of serious illness, caused by a woman having eaten freely of them, a sample of which was shown to me by her husband. These were picked up by several people about the same locality, and no doubt have caused great uneasiness, and possibly severe illness, as, according to my informant, they were eaten largely, in some cases by the handful. After reading such a case as this, the question naturally forces itself upon our attention, How is it that so poisonous a drug as Calabar bean is allowed to be throwing about our dock quays and waste places, apart from all consideration of its value as an article of commerce, for I find from the drug list its price to be 4*s.* per lb.? The difficulties of examining every cartload of rubbish going through the dock gates are, of course, great. I think something might be done to mitigate the evil by the dock board and the corporation,—the former by impressing on its officials the necessity of looking after the rubbish cleared from the holds of the west coast of Africa traders, for I believe the mischief is confined entirely to them, and the latter by prohibiting its deposit within the borough boundary.

9, *West Derby Street, Liverpool, July 18th,* 1871. T. H. Hustwick.

[*** The seeds sent are those of the oil palm of Africa (*Elæis Guineensis*), from which palm oil is obtained. The fatty oil is used largely on the West Coast of Africa for the same purposes as butter in this country.—Ed. Pharm. Journ.]

The "Bank Holidays."

Sir,—Messrs. Maw, Son, and Thompson have inserted a "Notice to the Trade," in their Price Catalogue, intimating that their establishment would be closed on the following days:—Good Friday, Easter Monday, Whit Monday, first Monday in August, Christmas Day, and Boxing Day. Is not this an example worthy of imitation by the wholesale trade generally? Not only will the banks be closed on these days, but many wholesale houses in various branches of commerce have determined to follow the same course. Why should the drug trade be an exception? If the plan were universally carried out, employers would suffer no pecuniary sacrifice; retailers would be put to no inconvenience, as they would be able to make provision beforehand, and those engaged in the wholesale would derive a great benefit.

M. P. S.
London, July 25th, 1871.

P.S. I do not see why the plan might not be largely adopted in the retail also.

Communications, Letters, etc., have been received from Mr. E. H. Chester, Mr. W. W. Stoddart, Mr. W. M. Betts, Mr. J. R. Jackson, Dr. Headland, Mr. J. H. Woods, Mr. J. Thornton, Mr. Tomlin, Mr. Horsley, Mr. Owen Jones, Mr. W. L. Yeats, Mr. Atkinson Pickering, N. O. P., M. P. S., W. G., "Veuve."

VESICATING INSECTS.

BY M. C. COOKE, M.A.

In order to enumerate and give some brief particulars of all the known vesicating insects that are or have been employed in medicine, it will be well to divide them into three groups, *i. e.* the Mylabridæ, the Cantharidæ, and the Meloëidæ. There will then remain only a miscellaneous few which cannot be included in any of the three groups, containing such insects as are known to have been employed as substitutes or adulterations. This classification is conformable to that adopted by entomologists, and will not therefore be open to the objection which may sometimes be urged against artificial arrangements for economic purposes.

Section I. Mylabridæ.

The number of species included by Gemminger and Herold ('Catalogus Coleopterorum') in the genus *Mylabris* is formidable, as compared with those described by Billberg in his monograph, published in 1813. Only a small proportion of these have any reputation as vesicants, but it is very probable that the majority of them are more or less possessed of vesicatory properties. It is to be regretted that an elaborate monograph by Marseul, read before the Entomological Society of France twelve months since, has not been published, but there have probably been excellent reasons why it has not appeared. War is no friend to science.

Chicory Mylabris or Telini Fly, *Mylabris cichorei*, Fabr.; villous, black; elytra black, with two spots, and two ochraceous bands.—Fabr. S. El. ii. p. 81; Oliv. 47, p. 7. t. 1. f. 1; *Meloë cichorei*, Linn. Syst. p. 680; Panz. Ins. 31. t. 18; Steph. Med. Zool. t. 26. f. 5; Billb. Mon. t. 1. f. 8, 9; De Geer's Insecta, iv. t. 13. f. 2; Pallas, Ins. Ross, t. E. f. 7; Moq.-Tand. Med. Zool. f. 32; Brandt and Ratzb. ii. t. 18. f. 17.

This species is the best known, and, according to Moquin-Tandon, is employed in Italy, Greece, Egypt, etc., as far as China. It is found in several of the warm parts of Europe, as well as in Asia, and resides on the flowers of the wild chicory, and other composite plants in Europe, and various plants in Asia. Attention was directed to this insect, as a native of India by Captain Hardwicke, in 1799. The following is his detailed description:* Antennæ moniliform, short, consisting of eleven articulations, increasing in size from the second to the apex; the first nearly as long as the last; each a little thicker upwards than at the base, and truncated, or as if cut off, the last excepted, which is egg-form. Palpi 4, inequalled, clubbed, the posterior pair of three, and the anterior of two articulations. Maxillæ or jaws four, the exterior horny, slightly curved inwards, 3-toothed, the two inferior teeth very small; the exterior pair compressed and brush-like. Head gibbous; eyes prominent, large, reticulated; labium or upper lip hard, emarginated. Thorax convex above, broader towards the abdomen, and encompassed by a narrow marginal line. Elytra crustaceous, the length of the abdomen, except in flies pregnant with eggs, when they are shorter by one ring; convex above, concave beneath; yellow, with three transverse, black, irregular undulated bands, the one at the apex broadest, and that at the base dividing the yellow longitudinally into two spots; porcated or ridged; the ridges longitudinal and parallel to the suture; in number, three equal, one unequal, the ridges not very prominent. Alæ or wings membraneous, a little exceeding the elytra in length, and the ends folded under. The tarsi of the two first pairs of feet consists of five articulations; and of the posterior pair four only. Every part of the insect excepting the wings and elytra is black, oily to the touch, and covered more or less with dense hairs; a few scattered hairs are also evident on the elytra. All the crustaceous parts of the insect are pitted minutely. It is about the bigness of the *Meloë proscarabæus* of Linn., and a full-grown one, when dry and fit for use, is to the *vesicatorius* in weight as four and a half to one.

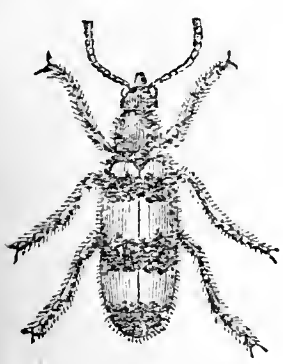

Fig. 1.

"They come into season with the periodical rains, and are found from the month of July to the end of October, feeding on the flowers of Cucurbitaceous plants, but more frequently on the species of *Cucumis* called by the natives "Turiey," with a cylindrical smooth, 10-angled fruit. Also on the "Raam-turiey," or *Hibiscus esculentus, Hibiscus Rosa-sinensis*; and in jungles where these plants are not to be found, they are to be met with on two or more species of *Sida*, which flourish in that season. In the failure of flowers, they will feed on the leaves of all these plants, except the "Turiey," which I have not observed them eat. They are great devourers, and will feed as freely in confinement as at large. In September they are full of eggs, which seems to be the best state in which they can be taken for medical use, at that time abounding more abundantly in an acrid yellow oil, in which, probably, resides their most active property. This fluid seems the animal's means of rendering itself obnoxious to others; for, on the moment of applying the hand to seize it, it ejects a large globule from the knee-joint of every leg, and this, if suffered to dry on the fingers, soon produces an uncommon tingling in the part, and sometimes a blister. This is the only inconvenience attending the catching of them, for they make no resistance; on the contrary, they draw in the head towards the breast as soon as touched, and endeavour to throw themselves off the plant they are found on. The female produces about 150 eggs, a little smaller than a caraway seed, white and oblong-oval. Their flight from plant to plant is slow, heavy, and with a loud humming noise, the body hanging almost perpendicularly to the wings. They vary in the colour of the elytra, from an orange-red to a bright yellow; but I do not find this variety constitutes any difference in sex. The natives of this part of the country know the insects by the name of "Tel-eene," expressive of its oily nature. It is stated by Captain Hardwicke to be found in all parts of Bengal, Behar and Oude.

In India this insect is known as the Telini fly, and the following synonyms have been traced by Mr. Moodeen Sheriff,—Zararihul-hind, or Zararihe-hindi of the Arabs; Dabane-hindi of the Persians; Telni, or Telni-makkhi of the Hindus; Bad-bo-ki-zirangi, or Zirangi of the Deccan; Pinsttarini of the Tamuls; and Blishtering-igelu of the Telugus. These names are probably applied to other species as well as the present, employed for like purposes.

There is an apparent discrepancy between the

* 'Asiatic Researches,' vol. v. 1799, pp. 213–215.

different descriptions which have been given of this fly, occasioned by the fact that some have regarded the ground colour of the elytra as black, with ochraceous yellow bands and spots; others treat the ochraceous yellow as the ground colour, with three black bands. O'Shaughnessy states that the Telini fly is common in the neighbourhood of Dacca, in the Hydrabad country and numerous other localities. If procured before the mites have commenced its destruction, it yields, on an average, one-third more of cantharidin than the Spanish fly of the European shops. "Some prejudice," he says, "exists against the article on account of its alleged excessive severity of action. This is solely owing to the presence of a greater quantity of cantharidin than that contained in the common fly. Diluting the tincture, and adding to the proportion of lard and wax in the plaster and ointment, perfectly assimilate the action of the indigenous and the imported insects."

Dr. Bidie* seems to doubt whether the insect found in the Mysore country was the same as Captain Hardwicke's, as will be seen by his remarks: "There is a species of *Mylabris*, very similar to Hardwicke's, found in abundance in the Mysore country, of which the following are the characters:—head gibbous; eyes large, prominent, antennæ with 11 joints, gradually ending in a club, and eleventh joint large and ovoid; thorax convex above, broader towards the abdomen, somewhat hairy; elytra crustaceous about the length of the abdomen, convex above, concave below, yellow, with three transverse, black, irregular, and undulating bands, that at the base dividing the yellow into two spots; wings thin, brownish, membranaceous, longer than the elytra, tips folded under; first 2 pairs of tarsi 5 joints each, last pair 4 only, last joint in all furnished with pair of claws. When touched, the insect ejects from the joints of its legs large drops of a yellow oily fluid of an acrid nature. They are very destructive to all the species of *Hibiscus*, to Roses, etc. When gathered they should be killed by being plunged into vinegar, and then dried in the sun. The month of September is said to be the best time for collecting them, and they should be stored in close-stoppered bottles, with a little camphor to preserve them from the attacks of insects." There is no good ground for supposing that there is any difference between the Mysore and Bengal insect. In the absence of specimens it is not easy to appreciate the doubts of local entomologists on closely allied forms. In both instances it seems that *M. cichorei* and *M. phalerata* are confounded together, the latter being specially fond of such Malvaceous plants as the species of *Sida* and *Hibiscus*.

Dr. Fleming says that this insect abounds in every part of Bengal, Bahar and Oude. In the rainy season, during which it is in its most perfect state, it is found feeding on the flowers of the various species of *Hibiscus* and *Sida*, and is readily distinguished by the three transverse, undulated black bands on its yellow elytra, which constitute its specific character. The flies should be gathered in the morning or evening, and immediately killed by exposing them to the steam of boiling vinegar. They should then be thoroughly dried by the heat of the sun, and afterwards put into bottles to preserve them from humidity.

EUCALYPTUS GUM.

BY PROFESSOR T. WIESNER.

The Austrian Pharmaceutical Society requested Professor Wiesner, of Vienna, to subject their collection of samples of Eucalyptus gum to an investigation, which he did the more readily as no reliable information on the subject existed.

The collection contained twenty different samples, some with the flowers and leaves of the plants. It had been received from Dr. Sonder, of Hamburg, and came from Dr. Ferd. Mueller, Director of the Botanical Gardens at Melbourne, to whom we are much indebted for our knowledge of the Australian flora.

The apparent similarity of this gum-resin to gum-kino, the dried juice of the bark of *Pterocarpus Marsupium*, Mart., has led to the conclusion that it is a species of kino, like the extract of the wood of *Coccoloba uvifera*, L., Jamaican kino, or the gummy substance from the bark of *Butea frondosa*, Roxb., Bengal kino.

But well-known authorities in pharmacognosy have been inclined to doubt the kino-like character, and to look upon it as merely a gum-resin impregnated with colouring matter. It therefore became necessary, above all, to determine the constituents of the Eucalyptus gum; and the author finds the principal part of all samples to be nothing but so-called kino tannic acid. He obtained by Berzelius's method a red, amorphous substance identical in all its reaction with kino tannic acid.

The gum was dissolved in water, and the flocculent, pale-red precipitate, obtained by adding sulphuric acid, was washed until acid reaction of the wash-water ceased; the precipitate was dissolved in boiling water, and separated after cooling from the insoluble matter. The red liquid was evaporated *in vacuo*, and yielded thin, red, transparent laminæ, which under the microscope appeared cracked and quite amorphous. The mass is slowly soluble in cold, but readily in hot water; the solution is adstringent. Alcohol, like hot water, gives a ruby-coloured solution; perchloride of iron produces a dirty green precipitate. The kino tannic acid obtained from kino itself gave with the iron salt a black-violet precipitate; but as the author is far from looking upon this acid as a definite chemical compound, he thinks he has proved the identity of the principal constituent of the gum under examination with kino. He adopts the name Eucalyptus kino, and he avoids the expression gum, because gums are mostly soluble in alcohol as well as in water. In Bentham and F. Mueller's 'Flora Australiensis,' the many extracts obtained from *Eucalyptus* are always called gums; and in vol. viii. p. 185, it is even stated that the *Eucalyptus* species yielded gum-resins, and therefore they were named gum-trees.

Pterocarpus kino contained, besides kino tannic acid, water, mineral substances with 1·3 per cent. of ash, a substance similar to pectine, catechine and a little pyro-catechine, but no sugar. Eucalyptus kino contained from 15 to 17 per cent. of water; it gave only a trace of ash, and no sugar was found. Several samples contained a little catechine. Pyrocatechine appears always to be present. A pectine-like substance could not be detected in any of the samples, but several samples contained a substance soluble in water, similar to gum arabic. The juices of *Eucalyptus gigantea*, Hooker, contained this substance in such quantity that several lumps were quite insoluble in alcohol.

The physical properties of Eucalyptus kino nearly agree with those of ordinary kino; it forms dark red, more or less transparent grains; in thin fragments, under the microscope, quite transparent and amorphous. They sink in cold water. Its specific gravity is 1110, after complete expulsion of the air 1140. Water dissolves it more or less readily to a red, yellowish or brownish liquid of astringent taste. Shaken with water, all samples gave a frothy solution.

The separate samples gave the following characteristic reactions, viz. kino from—

1. *Eucalyptus corymbosa*, Sm. Of all samples most readily soluble in water. Solution deep blood-red; smells distinctly like Bordeaux wine, slightly acid, turbid on cooling, free from gum-resin. Bright shining surface of fresh fraction of lumps. Colour deep red.—Bloodwood gum. Victoria and New South Wales.

2. *E. globulus*, Labill. Readily soluble in water. Solution pale reddish-yellow, slightly acid, very turbid on cooling; on heating becomes clear again. No gum-resin; crumbling masses of light brownish-red colour.

3. *E. rostratus*, Schlecht. = *E. rostrata*, Cav. = *E. robusta*, Sm. Easily soluble in water and alcohol; solution neutral, free from gum-resin. Broken masses of a zircon red, sometimes light brown, mixed with bits of bark. This and several other samples are named red gum.

4. *E. leukoxylon*, F. Mueller. Same reaction as *E. globulus*. Large black-red lumps, with fibrous impurities.

5. *E. corynocalyx*, F. Mueller. Slowly but completely soluble in water; solution slightly acid, yellow red, on cooling turbid, no gum-resin. Broken reddish-brown lumps, fatty lustre, mixed with particles of bark.

6. *E. citriodora*, Hook. Easily soluble in water; solution faintly acid, smells like Bordeaux wine, yellow colour, turbid on cooling. Porous lumps with greenish lustre, like Socotrine aloes, mixed with bark. Queensland.

7. *E. maculata*, Hook. Exactly like the last. New South Wales. Goes by the name of spotted gum.

8. *E. calophylla*, R. Br. Readily soluble in water; solution yellow, slightly acid, becomes turbid on cooling, free from gum-resin. Irregular grains, light brown or red.

9. *E. amygdalina*, Labill. Easily soluble in water; solution neutral, onion-red, turbid on cooling. Black particles, and only in very thin fragments, zircon-red in transmitted light, fatty lustre, very tough, rich in fibrous bark.

10. *E. piperita*, Sm. Easily soluble in water; solution yellowish-red, neutral, free from gum-resin. No turbidity on cooling. Dense pieces of zircon-red, translucent.

11. *E. pilularis*, Sm. Readily soluble in water; red solution, faintly acid, turbid on cooling, traces of gum-resin. Pieces, opaque, earthy, or with slight fatty lustre, dark reddish-brown. Known as Black's bottle gum.

12. *E. fabiorum*, Schlecht. Not readily soluble in water; solution yellowish, faintly acid, turbid on cooling, contains gum-resin. Particles, dark black-red, slightly transparent, shiny fracture.

13. *E. fissilis*, Muell. Reddish solution, neutral, remaining clear on cooling, trace of gum-resin. Tough drops, blackish-red, zircon-red, translucent, fatty lustre on fracture.

14. *E. gigantea*, Hook. Little soluble in water; solution brownish, neutral, no turbidity, rich in gum-resin. Tough, drop-like pieces, of a zircon-red.

15. *E. viminalis*, Labill. Only partly soluble in water, with light-brown colour, contains a little gum-resin. Brittle, like kino.

16. *E. obliqua*, L'Hér. Taken as identical with *E. gigantea*. Completely soluble in water, with deep red colour, neutral, no turbidity, free from gum-resin. Looks like kino.

These samples show a pretty uniform reaction; they all give with sulphuric acid a pale red, flocculent precipitate; the aqueous solution always gave with perchloride of iron a dirty green precipitate, with the exception of *E. obliqua*, which gave a dark violet coloration. The precipitate is, of course, owing to kino tannic acid; and the one exception is explained by the above-named characteristics of this acid.

The solutions of the different samples give, on addition, first of muriatic acid and then of ammonia, precipitates of different colours. No. 14 gives a yellowish-red precipitate, which, on exposure to air, becomes of a rusty red. No. 16, dark violet precipitate. The precipitate with No. 15 blackens in the air. Ammonia added to the original solution produces no effect, except a deeper coloration; chloride of ammonium is indifferent.

There are many statements in literature as to the origin of this substance. *Eucalyptus resinifera*, Sm., is generally said to be the plant from which it is taken, but it was exactly the drug obtained from this plant which led Flückiger to the belief that it was merely a coloured gum. The author obtained from Dr. Moore, Director of the Botanical Gardens at Sydney, a sample of gum from the Paris Exhibition, section New South Wales, which was taken from *E. resinifera*. It was found to be a genuine gum-resin, and the author has reason to assume that this gum-resin, which voluntarily oozes out from the tree, is a product of *E. resinifera*, together with the Eucalyptus kino. Bentham and Mueller give two different gums from the same tree, viz. a grey gum, very likely the true gum-resin, and a "red gum," which, no doubt, is a species of kino.

Many of the above-named botanical species have hitherto not been known to yield any gum.

Nothing is known about the preparation of the substance, but the presence of bits of bark lead to the idea that it has been obtained from the bark. The look of the Eucalyptus kino, the similarity with ordinary kino and the presence of pyrocatechine in several samples, point to the conclusion that it is an extract from the bark obtained by artificial drying.

The Eucalyptus kino, like catechu or ordinary kino, is applicable for tanning and dyeing. According to Messrs. J. Rosisto and Co., of Melbourne, large quantities may be obtained. The value of the samples varies very much, the best are from *E. corymbosa*, *E. rostrata* and *E. citriodora*; the least valuable from *E. fabiorum*, *E. gigantea* and *E. viminalis*.—*Zeitschr. d. allg. Oest. Apotheker-Vereines.*

THE ACTION OF HYDROBROMIC ACID ON CODEIA AND ITS DERIVATIVES.

BY C. R. A. WRIGHT, D.SC.

(*Concluded from page* 86.)

The portion insoluble in ether of the batch from which hydrochlorate B was obtained was treated with HCl, and fractionally precipitated by strong acid several times successively. This mode of treatment was adopted rather than that with HBr, as a much larger yield is obtained thus, the hydrochlorates of chlorotetracodeia and chlorotetramorphia being much less soluble in dilute HCl than the corresponding brominated bodies are in dilute HBr. Finally, nearly white flakes were obtained, presenting all the characters of chlorotetramorphia hydrochlorate, and yielding the following numbers after drying at 100°:—

0·2480 grm. gave 0·5610 CO_2 and 0·1410 H_2O.
0·1390 grm. gave 0·0755 AgCl.

	Calculated.		Found.	
C_{68}	816·0	61·79	61·70	
H_{79}	79·0	5·98	6·32	
Cl_5	177·5	13·44	..	13·45
N_4	56·0	4·24		
O_{12}	192·0	14·55		
$C_{68}H_{75}ClN_4O_{12}, 4HCl$	1320·5	1000.00		

Hence the portion insoluble in ether must have been bromotetramorphia.

The simultaneous formation of bromotetramorphia and deoxymorphia from bromocodide is explainable in two ways, either—

(I.) $$\underbrace{5C_{18}H_{20}BrNO_2}_{\text{Bromocodide.}} + 4H_2O$$
$$= \underbrace{C_{72}H_{83}BrN_4O_{12}}_{\text{Bromotetracodeia.}} + \underbrace{C_{18}H_{21}NO_2}_{\text{Deoxycodeia.}} + 4HBr.$$

(II.) $$\underbrace{C_{72}H_{83}BrN_4O_{12}}_{\text{Bromotetracodeia.}} + 4HBr$$
$$= \underbrace{C_{68}H_{75}BrN_4O_{12}}_{\text{Bromotetramorphia.}} + 4CH_3Br.$$

(III.) $$\underbrace{C_{18}H_{21}NO_2}_{\text{Deoxycodeia.}} + HBr = \underbrace{C_{11}H_{19}NO_2}_{\text{Deoxymorphia.}} + CH_3Br;\ \text{or}$$

(IV.) $$\underbrace{C_{18}H_{20}BrNO_2}_{\text{Bromocodide.}} + HBr = \underbrace{C_{17}H_{18}BrNO_2}_{\text{Bromomorphide.}} + CH_3Br.$$

(V.) $$\underbrace{5C_{17}H_{18}BrNO_2}_{\text{Bromomorphide.}} + 4H_2O$$
$$= \underbrace{C_{68}H_{75}BrN_4O_{12}}_{\text{Bromotetramorphia.}} + \underbrace{C_{17}H_{19}NO_2}_{\text{Deoxymorphia.}} + 4HBr.$$

Of these two views, the first involves only known substances and reactions similar to those already known in the codeia series of derivatives, and is, moreover, probable from the circumstances that the numbers obtained in some instances indicate the presence of deoxycodeia as well as deoxymorphia; whilst the second view involves the not improbable existence of bromomorphide, $C_{17}H_{18}BrNO_2$; on the other hand, it will be shown in the next section that equation (III.) represents a reaction which does not readily take place with deoxycodeia, when not in the nascent condition at any rate.

Whichever view be adopted, the ultimate formation of bromotetramorphia requires the action of water on a brominated body, substituting hydroxyl for bromine by a reaction perfectly parallel to that whereby codeia is regenerated from chlorocodide by the action of water,* viz.:—

$$C_{18}H_{20}ClNO_2 + H_2O = HCl + C_{18}H_{21}NO_3.$$

3. *Action of Hydrobromic Acid on Deoxycodeia.*

In the hope that this action would give rise to methyl bromide and deoxymorphia, deoxycodeia hydrobromate was heated to 100° for two hours with about five parts of 48 per cent HBr; no change whatever took place, no methyl bromide being found on opening the tube in which the digestion was carried on after complete cooling. After an hour's additional exposure to a temperature of 120°–130°, the contents of the tube were found to have become black and tarry, while a small quantity of methyl bromide floated on the top. Precipitated by sodium carbonate, a very dirty substance was obtained, which was almost insoluble in ether; the ethereal extract, shaken with HBr, gave a small quantity of a tarry hydrobromate, of which 0·1330 grm. gave 0·0790 AgBr, or Br = 25·20 per cent., deoxymorphia hydrobromate requiring only 22·86 per cent.

Nothing fit for analysis could be obtained from the portion insoluble in ether, and the minute yield of pure deoxycodeia from codeia precluded a repetition of the experiment.

4. *On the Physiological Action of the Foregoing Codeia Derivatives.*

BY MICHAEL FOSTER, M.A., M.D.

The hydrochlorate of chlorotetracodeia and the hydrobromate of bromotetramorphia, in doses of a decigramme by subcutaneous injection or by the mouth, produced in adult cats in a very few minutes a condition of great excitement, almost amounting to delirium, accompanied by a copious flow of saliva and great dilatation of the pupils. Micturation and defæcation occurred in some instances, and vomiting was observed on two occasions with the morphia-salt, but was very slight. The excitement was very peculiar, being apparently due partly to increased sensitiveness to noises, and partly to an impulse to rush about.

The same doses of the morphia-salt given to a young kitten produced the same flow of saliva, dilatation of pupils, and excitement (without vomiting); but the stage of excitement, which in adult cats passed gradually off in a few hours, was followed by a condition marked by a want of co-ordination of muscular movements, and presenting the most grotesque resemblance to certain stages of alcoholic intoxication. This stage was followed in turn by sleepiness and stupor, in which the kitten was left at night; in the morning it was found dead.

Two observations have shown these salts paralyse (in dogs and cats) the inhibitory fibres of the pneumogastric; they also seem to lower the internal tension, but want of material has prevented from ascertaining how this is brought about.

On *rabbits* neither salt, even in doses of a decigramme, seems to have any effect, except perhaps a slight excitement. There is no dilatation of the pupils, no flow of saliva, and, if one observation can be trusted, no paralysis of the inhibitory fibres of the pneumogastric.

No marked difference was observable between the two salts, except that the morphia salts seemed rather more potent than the corresponding codeia bodies.

The salts of deoxycodeia and deoxymorphia given by mouth or by subcutaneous injection, in doses of a decigramme, produced in adult cats, almost immediately after exhibition, a series of convulsions much more epileptic in character than tetanic. In one case there was a distinct rotatory movement.

In a few minutes these convulsions passed away, leaving the animal exhausted and frightened. Then followed a state of excitement with dilated pupils and flow of saliva, very similar to the effects of the tetracodeia and tetramorphia salts, but less marked.

* Matthiessen and Wright, *Proc. Roy. Soc.*, vol. xviii. p. 88.

Doses of half a decigramme given to adult cats produced the state of excitement only without the convulsions.

In no case, with any specimen of product, has vomiting been witnessed.

Trials with rabbits gave only negative results. Like the tetracodeia and tetramorphia products, the deoxycodeia and deoxymorphia salts appear to paralyse the inhibitory fibres of the pneumogastric.

No marked differences could be observed between the hydrochlorates and hybromates of deoxycodeia or deoxymorphia.

THE MODERN ASPECTS OF THERAPEUTICS.

BY WALTER G. SMITH, M.D.

(*Continued from page* 87.)

It has lately become the fashion to decry the study of materia medica, and it is asserted that the possession of such knowledge is a useless burden on the memory. I am persuaded that this is a mistake, and a serious one, and I am sure that many will from repeated experience bear me out in the belief that an accurate knowledge of the characters and properties of drugs is of every-day utility to the prescriber, in enabling him to formulate correctly, to detect imposture, to avoid improper combinations, and to explain any phenomena that may unexpectedly arise.

Since our ignorance of the curative resources of the organism, and of the healing powers of drugs have been, and still are, the chief sources of error in therapeutics, and the chief obstacles to its improvement, it follows that the foundation-stone for positive knowledge must be laid in more accurate investigations into the real properties of drugs, and this leads me to consider how we may best set about such improvement, and in what directions we can look for assistance in such a course. I shall pass over without further reference the direct gains to therapeutics, and the lessening of the chances of confusion which flow from improved methods of diagnosis, from the more strict localization and classification of disease, and from the prosecution of physiological and pathological studies, and will direct attention, in the first place, to the influence which organic chemistry and physics are now extending over practical medicine.

The outcome of all recent developments in science, and, in especial, the doctrine of the correlation of force, *i.e.* the indestructibility or conservation of energy, the corner-stone of science, has been to render it in the highest degree probable that plants and animals are under the operation of the same laws as inorganic nature, and that all the changes and processes which are unceasingly at work within us are mainly the result of the action of physical and chemical forces upon the material constituents of our frame. The human body has often been compared to a machine, and though the comparison between a living body and an inanimate machine should not be pushed too far, still the forces operating on each can reasonably be compared, and the more closely we know the limits of health, and the deviations that may occur from it consistent with life, the more surely can we propose to rectify the errors in function. Hence it is plain that a truly expressed science of medicine cannot be evolved except by endeavouring to refer the processes going on in the animal body, and therefore also the influence of remedies on these, to the ultimate laws of physics, chemistry, and physiology. "Chemical inquiry is now finding its way into many of the remoter secrets of function, and is likely before long to establish some laws of molecular constitution which will enable us to classify unknown remedies, and to explain and calculate their actions." (Dr. Allbutt.)

The observations of Bence Jones and Dupré, who were the pioneers of this work in this country, have disclosed a rich mine of discovery, and they have demonstrated the existence of a chemical circulation within the body, which rivals in importance that of the older mechanical circulation of the blood. By the application of spectrum analysis they have shown the wonderful rapidity with which crystalloids diffuse from the blood into the colloid tissues, and from the tissues into the absorbents, and so the passage of all substances through the human body is determined by the laws of diffusion, modified by pressure. For example, if 20 grs. of carbonate of lithium are taken into the stomach, it will, in two and a half hours, have passed into every particle of the textures, and beyond the blood circulation even into the most distant parts, and in three and a half hours it will be distinctly present in each particle of the lens. In about seven days the lithium will be entirely eliminated from the body. When 7 grs. of carbonate of lithium were given eight hours before delivery, the lithium was subsequently detected in each particle of the umbilical cord.

Again, they have determined the existence, in animals, of a widely diffused substance which closely resembles quinine, and which has been named animal quinoidine. This leads to a plausible supposition, the only one yet offered, as to the mode of action of quinine in curing ague, and the hypothesis, though not proven, opens up a hopeful prospect of possible discovery.

The history of organic synthesis dates only from the year 1828, and remained comparatively barren for some years, but since the year 1845, its progress has been truly marvellous. The most complex substances are being formed at will, while the last barriers between organic and inorganic bodies are disappearing, and as the advances in this branch of science are, if I may say so, in the highest degree cumulative, the time is probably not far distant when, by the artificial formation of morphia and quinia, we shall be able to dispense with the production of opium, and the cultivation of cinchona in our colonies.

Every schoolboy is now familiar with the derivation of the most diverse colours from coal tar, and it is but the other day that alizarine, the colouring principle of madder, has been built up from another component of coal tar—the first instance of the artificial production of a vegetable colouring matter. We have just learned that artificial indigo has been isolated, and we may confidently hope soon to see the alkaloids brought into the market, derived not from their natural sources, and dependent on precarious supplies, but furnished to us by the laboratory of the chemist—the true magician of our age. [Even since these lines have been written, Schiff has announced the first attainment of this result in the artificial formation of conia.] The insight which we shall thus gain into the constitution and intimate nature of complex organic molecules must prove of inestimable value as a stepping-stone to a true classification of remedies. So comprehensive is the aim of modern chemistry, and so wide the means of research, that "we can foresee a state of chemistry in which, without studying the properties of different bodies in detail, and knowing only the number, atomicity, and electric polarity of the elements, it will be possible to determine by simple calculation the formulæ, properties, and mode of preparation of all compounds possible." (Naquet.)

In a philosophic and suggestive paper, Dr. Broadbent has made a bold attempt to apply chemical principles in explanation of the action of remedies and poisons, in which are contained, I believe, the elementary principles of scientific therapeutics. Starting from the two postulates—1st. That there must be some relation between the substance administered and the human organism on which the effects produced depend. 2nd. That, so far as the substance is concerned, the basis of the relation can only be its *chemical* properties, using this term in its widest sense, certain important corollaries flow from these:—1. That the physiological and therapeutical actions of the same substance must be similar in kind. 2. That the action of foods, medicaments, and poisons in the system, must be capable of explanation on the same principle. 3. That substances closely allied chemically, must have an analogous action on the system, or the diversity in their operations should be capable of explanation on chemical principles; in other words, chemical groups ought to form therapeutical groups. This is an outline of the path to be pursued, and some steps of importance have been already gained by individual workers. In England and Scotland the names of Bence Jones, Richardson, Crum Brown and Fraser, stand out in honourable relief; in France, among a number of observers, Mialhe, Rabuteau and MM. Pélissard, Jolyet, and Cahours; and in Germany, Liebreich, Binz and many others have pursued the investigation of the physical and chemical action of drugs with results most encouraging, though as yet imperfect and incomplete.

In determining the action of any substance from a chemical point of view, Dr. Richardson has shown that we have to consider five points, viz.:—1. The elementary basic or radical composition of the substance to be tested, and the changes of constitution to which it may be subjected; 2. The physical qualities of the substance; 3. The chemical stability of the substance; 4. The physical peculiarities of the animal body subjected to the substance; and 5. The special action of the substance on special centres of the animal organism.

Some scattered attempts to express the relation which, no doubt, exists between the physiological action of a substance and its chemical composition and constitution (*i.e.* the mutual relation of the atoms in the compound) have, from time to time, been made, but until lately with trifling success. For example, it has long been observed that, as a rule, the salts of the same base and of the same acid have respectively a common physiological action, and Mr. Blake, of California, pointed out many years ago, and has lately extended his experiments, that, in general, isomorphous substances have analogous actions.

(*To be continued.*)

SUNFLOWER-SEED OIL.

The highly ornamental and extensive genus of plants to which this plant belongs derives its scientific name, *helianthus*, from *helios*, sun, and *anthos*, a flower, on account of the brilliant colour of the flower, and from the erroneous idea, propagated by poets and others, that the flowers always turned towards the sun—hence, also, the French name *tournesol*. It appears to possess far more profitable qualities than have been hitherto supposed, and may be cultivated with advantage and applied to many useful purposes. An acre of land will contain 25,000 sunflower plants, at twelve inches distance from each other.

The great variety of valuable properties belonging to the sunflower seed have been much neglected. No plant produces such fine honey and wax, and when the flower is in blossom, bees abound on it. The produce will be according to the nature of the soil and mode of cultivation; but the average has been found to be fifty bushels of the seed per acre, which will yield fifty gallons of oil. The oil is excellent, when refined, for table use, for burning in lamps, for soap making, and for painting —especially for mixing green and blue paints. The marc, or refuse of the seeds of the above quantity after the oil has been expressed, made into cakes, will produce 1500 lb., and the stalks, when burnt for alkali, will give 10 per cent. of potash. The green leaves of the sunflower, when dried and burnt to powder, mixed with bran, make excellent fodder for milch cows. It makes a beautiful soap, particularly softening to the hands and face, and is pleasant to shave with. The cake is superior to linseed for fattening cattle. Sheep, pigs, pigeons, rabbits, poultry of all sorts, etc., will fatten rapidly upon it, and prefer the seed to any other; it causes pheasants in particular to have a much more glossy plumage and to be plumper in the body. It also increases the quantity of eggs from poultry fed with it. The seed, shelled, makes when ground very fine sweet flour for bread, particularly tea-cakes.

The sunflower will grow in any corner that may be vacant, and will give a farm a most agreeable garden-like appearance. It should be planted about six inches apart, and about one inch deep, and when about one foot high should be earthed up; it then will require no further attention. Every single seed will produce 1000 or more; the main head generally produces 800 to 1000 seeds, and there are usually four collaterals, producing 50 to 60 seeds each. But it is not the seed only that is valuable, for by treating the stalk exactly as flax, it will produce a fibre as fine as silk, and that in large quantities. Now that rags have become so valuable, arising from the unprecedented demand for paper, the stalk might be made useful for that purpose.

On some grounds two crops may be growing at the same time. When the farmer has given his early potatoes a last hoeing, he may plant this seed twelve inches apart in the ridges. The Chinese have it by thousands of tons and worship it. There can be no doubt that many of their silk goods have a large portion of the sunflower fibre in them. According to Boussingault, some experiments made by M. Gauzac, of Dagny, gave the produce per acre of seed, at 15 cwt. 3 qr. 14 lb.; the oil per acre 275 lb., being 15 per cent. and the cake 80 per cent. Next to poppy-seed oil, sunflower oil burns the longest of any in equal quantities. The seeds vary in colour, being either white, grey, striped or black. From them is expressed a palatable clear and flavourless oil, the demand for which in Russia is very great. It is exported from St. Petersburg at about 10*s.* 6*d.* the cwt., and is said to be extensively used, like cotton-seed oil, after purifying, for adulterating olive or salad oil.

In Russia a considerable quantity is grown for oil pressing. The plant is largely cultivated in Kiels and Podolia, eastward on the black soil lands. The stalks are used for fuel. The manufacture of the oil, which was formerly confined to the Government of Voroneje, has recently been carried on in that of Saratov, and in the town of that name, there were, in 1867, at least thirty oil-presses. Mr. Alexander Knobloch, of Sarepta, has one worked by steam power. The seed is supplied by the peasants of the neighbourhood. The production in Russia in 1867 (including a few other miscellaneous oil seeds) was officially stated at 335,000 cwt. At Voroneje 6000 to 8000 poods (of 36 lb.) of seeds are produced. In Russia the seed sells at about 40 copecks the pood, or 2 roubles 60 copecks the chetwert; the oil at $3\frac{1}{2}$ to 4 roubles the pood.—*Journal of Applied Science.*

BRITISH PHARMACEUTICAL CONFERENCE.

On Thursday evening the British Pharmaceutical Conference Dinner was held in the Royal Hotel, Edinburgh. There was a large attendance. Mr. BAILDON occupied the chair; Mr. G. BLANCHARD acted as *croupier*. The usual loyal and patriotic toasts were succeeded by the following: "Success to the British Pharmaceutical Conference," proposed by the CHAIRMAN, replied to by Mr. STODDART; "The Colleges of Physicians and Surgeons," proposed by the *croupier*, acknowledged by Dr. ALEXANDER WOOD; "Prosperity to the Pharmaceutical Society of Great Britain," proposed by Professor ARCHER, replied to by Mr. T. H. HILLS; "The Officers of the British Pharmaceutical Conference," by Mr. FLUX, responded to by Mr. G. F. SCHACHT and Doctor ATTFIELD; "The Memory of the Founder of the Pharmaceutical Society;" "The Edinburgh Committee of the Conference," proposed by Mr. DEANE, acknowledged by Mr. BAILDON and Mr. MACKAY; "The Visitors," by Mr. J. R. YOUNG, responded to by Mr. DEANE, Mr. T. H. HILLS and Dr. EDWARDS; "The Pharmaceutical Associations of America and Canada," proposed by Mr. HANBURY, replied to by Dr. EDWARDS; "The Pharmaceutical Press," proposed by Mr. CARTEIGHE, and replied to by Dr. PAUL and Mr. WOOTTON. Other toasts were "The Ladies," "The Croupier."

The Pharmaceutical Journal.

SATURDAY, AUGUST 5, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE CONFERENCE MEETING.

THE success that we anticipated some months ago would attend the meeting of the Conference at Edinburgh has been fully realized, and the weather, though fickle, has been sufficiently fine to admit of the various attractions of the city being duly appreciated.

After the delivery of the address, which will be found at page 112, and after the usual votes of thanks had been proposed and passed, the further business of the meeting was commenced by Professor WRIGHT, of St. Mary's Hospital, reading a paper on Some Oxidation Products of Essential Oil of Orange Peel, and then giving an interesting account of the results obtained in his experiments on codeia, part of which have already been published in this Journal. This investigation, connected with a material of great importance in pharmacy, has well served to illustrate how much the chemist's capacity of detecting differences has been developed in advance of his power of giving verbal expression to the differences he has made out to exist between substances. In a report on the chloral of trade, Mr. MASON expressed himself satisfied with the quality of this medicine, and Mr. PATTISON MUIR sent a paper on the same subject, in which he stated that his results are consistent with those published in this Journal some months ago. The remaining papers read on Tuesday were "Pharmaceutical Notes on *Rhamnus Frangula*, Linn.," Mr. H. C. BAILDON; "The Compound Iron Mixture of the British Pharmacopœia," Mr. C. A. STAPLES; "Report on the Purity of the Permanganate of Potassium of Pharmacy," Professor ALLEN, F.C.S.; "On the Use of Blistering Flies in Hydrophobia," HENRY GROVES, Florence; "Solutions," T. B. GROVES, F.C.S. Some account was also given of a new method of dealing with meat for the purpose of preservation, and Mr. BAILDON described a new wire-guard for the protection of persons engaged in bottling aerated waters.

On Tuesday evening the Conversazione was held in the rooms of the Museum of Science and Art, at which about fourteen hundred ladies and gentlemen were present. Among the visitors was his Majesty the EMPEROR OF BRAZIL, who arrived about eleven o'clock. A selection of band and pipe music was performed by the band of the 93rd Sutherland Highlanders, and during the evening photographic views of Scottish scenery and buildings were exhibited by the aid of the oxy-hydrogen light.

On Wednesday, the first two papers read were on "The Crystalline Principles in Aloes," one by Professor FLÜCKIGER, the other by Messrs. T. and H. SMITH. These papers gave rise to a lively and prolonged discussion. After these, papers were read by Mr. GREENISH on "Linseed and Linseed Meal," and by Mr. STAPLES on "The Tincture Press." Another paper, by Professor FLÜCKIGER, was on "Wild Rue, *Semen harmalæ*," and a second paper by Mr. STAPLES was on "A Mode of obtaining Distilled Water."

Dr. EDWARDS then made some verbal remarks on cheap microscopes and apparatus. Following this, Mr. ATKINS read a paper on "Pharmaceutical Ethics," which called forth remarks from the PRESIDENT, Mr. SCHACHT, Mr. MACKAY, Mr. DEANE, Dr. EDWARDS and other members of the Conference; others also desired to speak, but the time of closing the meeting having passed, it became necessary to take as read the papers on the "Preparation of Liquor Bismuthi," by Mr. C. H. WOOD, and on "Pharmacopœial Nomenclature," by Mr. C. R. C. TICHBORNE, and proceed to the remaining business.

All these papers, or abstracts of them, together with a full report of the discussions, will appear in the next few numbers of the Journal.

On the motion of Dr. PROCTOR and Mr. KINNINMONT, a unanimous vote of thanks was passed to the readers of papers.

On the motion of Mr. SCHACHT, Mr. SAVAGE and Mr. ATKINS, an equally unanimous vote of thanks was passed for the efforts of the Edinburgh pharmacists in organizing for the Meeting and for the hospitality shown and already in store for visitors to the Conference,—especially connecting with this vote the names of Mr. MACKAY and Mr. BAILDON.

The Meeting then proceeded to the election of officers. A letter from Mr. REYNOLDS resigning the post of Secretary was read and called forth a lively expression of regret, which Professor ATTFIELD was requested to express to Mr. REYNOLDS.

The following were then chosen office-bearers for the ensuing year:—

President: Mr. H. B. BRADY.

Vice-Presidents: Messrs. H. DEANE, D. HANBURY, W. W. STODDART, R. BENTLEY, J. INCE, J. WILLIAMS, R. REYNOLDS and SAVAGE.

Mr. F. B. BENGER was elected General Secretary in place of Mr. REYNOLDS, and Mr. T. GLAISYER Local Secretary at Brighton.

The proceedings of this year's Meeting were brought to a close on Thursday evening by the usual Dinner, which was provided at the Royal Hotel. About eighty or ninety members dined together, the

Executive Committee being the guests of the resident members. A list of the toasts will be found in another column.

LIME AND LEMON-JUICE.

According to the terms of a statement made in the Pharmaceutical Journal of the 1st ult., we have now to lay before our readers a condensed *résumé* of evidence that exists as to the antiscorbutic value of lime and lemon-juice. Prior to the year 1795, scurvy was a very great bane to the sailor and caused much mortality. In 1780, according to Budd, "the squadron under Admiral Geary, after a cruise of ten weeks in the Bay of Biscay, returned to Portsmouth with 2400 men affected with it." But in the year above quoted lemon-juice was introduced into the Royal Navy, and in 1813 the diminution of sick and of deaths was in the proportion of nearly four to one. Thus much for the prophylactic effects of the juice. But as both lime and lemon-juice are costly, and are kept with difficulty in good condition, many trials have been made of ingredients that enter into its composition. Citric acid has been extensively tried in convict ships and elsewhere as a *curative* agent in cases of scurvy, and the verdict given by most authorities is decidedly favourable. The potash theory has been strongly maintained by Dr. Garrod, but has failed to receive support or favourable proof from practical men. The virtues of phosphorus have been lauded by John Morgan, of Dublin, whose theory was at the outset unsound, in that he failed to perceive that, in the form proposed, no assimilation of phosphorus in the system could possibly take place. In point of fact, most writers, however sincere they be, have omitted to recognize the fact that the prophylactic, and not the curative agent is the important point to be determined. Lime and lemon-juice contain citric acid, sugar, gum and potash, with a small proportion of malic, tartaric and phosphoric acids. Citric acid has been given in the mercantile marine in lieu of lime and lemon-juice, with scurvy as the result, and the Merchant Shipping Act of 1867 (commonly called the Duke of Richmond's Act) was passed to ensure the issuing good juice to the crews of merchant ships. Since this Act has taken effect, the admissions for scurvy into the Seamen's Hospital have decreased by 70 per cent., and we must therefore believe that some practical sanitary good has accrued. But Mr. Palmer believes that the same amount of benefit may be as completely and more economically derived from the use of citrate of potash. We are not prepared to deny the soundness of the theory, but as practical proof cannot at present be brought to its aid, we must be content to lay the foregoing statements before our readers, and still think that chemists may assist by suggestions to find out, for the benefit of the physician and his patients, the special antiscorbutic ingredients of lime and lemon-juice.

THE BRITISH ASSOCIATION.

The Forty-first Meeting of the British Association, and its third visit to Edinburgh, commenced on Tuesday last. The success of the meeting, in point of numbers, is now well assured, 2094 tickets having been issued against 1241 in the year 1850, when the Association last visited that city.

At the Meeting of the General Committee a Report was read stating that arrangements had been made for the transfer of the Kew Observatory to the Royal Society, in accordance with the terms of the Gassiot trust, and recommending that it should at once be carried into effect. Other matters treated of in the Report were the assistance rendered by the Government for the proper observation of the solar eclipse of 1870, the promotion of scientific education in elementary schools, and the metric system of weights and measures. It announced the retirement of Dr. Hirst from the office of Joint-General Secretary of the Association, and recommended the appointment of Captain Douglas Galton, C.B., F.R.S., as his successor. The report also stated that a central office had been opened in London, at 22, Albemarle Street, to which place the books and MSS. formerly deposited at Kew had been removed.

Dr. Richard King proposed the formation of a separate Ethnological section, and considerable amusement was caused by the speech in which he enforced his views. The subject was remitted to the Committee of Recommendations to report upon.

In the evening, Professor Huxley having uttered a few words of graceful recognition of the kindness received during his year of office, introduced his successor, of whom he said that "gentler knight there never broke a lance." Sir William Thomson then proceeded to deliver his inaugural address. We regret that from its great length we are unable to reproduce the whole of it this week. There is little doubt but that while the scientific facts will be received with the respect due to the speaker, and the ability with which they were discussed, some of the speculation contained in the address will be sharply challenged. But it appears to be *en règle* to look forward to a certain amount of heterodox speculation at the meetings of the British Association; and one author attempts to counteract the harm that may possibly be effected this year by advertising in Edinburgh "An Antidote against the Unscriptural and Unscientific Tendency of Modern Geology, with Remarks on Several Cognate Subjects."

True to her hospitable traditions, Edinburgh is already meeting her guests much more than halfway. The Committee of Management of the University Club has elected, as honorary members of the same, a number of gentlemen now assisting at the British Association. According to the circular issued by the Committee, the use of the Club will be available to the honorary members from the 31st ult. to the 11th instant.

We would direct attention to the resolution of the Council at their last meeting, affecting occasionally the regular issue of the Journal. The proceedings of Council are in future to be published in the next issue of the Journal after the meeting, and "the Journal may on those occasions be issued on Saturday morning instead of Friday as heretofore, if necessary."

The following paragraphs, in reference to the Pharmacy Act (1868) Amendment Bill, occur in the Report recently made by the Medical Officer to the Lords of Her Majesty's Privy Council:—

"Under the provisions of the Pharmacy Act, 1868, described in my last year's report, I conveyed to the Pharmaceutical Society, in 1870, your Lordship's approval of the Society's annual list of examiners for the purposes of the Act, and have now to submit to your Lordships the satisfactory report made by Dr. Greenhow on the London examinations of the Society in 1870, as visited by him for your Lordships' information.

"I regret to report to your Lordships that the power which, for the public protection, the first section of the Act vests in the Pharmaceutical Society, to prescribe (with consent of the Privy Council) regulations as to the keeping, dispensing, and selling of poisons, is still entirely unexercised. I believe it to have been by an accidental oversight in legislation, that, while all other powers to be exercised for public purposes by the Society under the Act were vested in the Council of the Society, the language of the first section vested in the Commonalty, and not in the Council, the very important power which that section confers, and to which my present observations relate. It is, perhaps, not surprising that a large body of tradesmen should be slow to take the initiative in imposing even the most reasonable penal restrictions on themselves; but I have to submit to your Lordships, as a fact which you may deem deserving the consideration of Parliament this that non-fulfilment of the Society's duty, to make rules against dangerous slovenliness in the keeping, dispensing and selling of poisons, is a breach of the implied contract under which the Legislature in 1868 gave powers and privileges to the Society."

A Committee has been formed with the object of raising a suitable memorial to the memory of the late Professor William Allen Miller. The Rev. Principal Barry, of King's College, has been chosen chairman, Professors Bentley and Bloxam and Messrs. Cunningham and Tomlinson as secretaries, and Professor Guy as treasurer. The ordinary subscription is to be one guinea, but the list of subscribers will be published without any statement of the amounts subscribed. It is intended to devote the funds which may be raised, first to obtaining a bust or portrait of Dr. Miller, and then to the institution of a prize or scholarship bearing his name, in connection with King's College.

Nature states that M. Wurtz has announced to the French Academy the success of a young chemist in his laboratory in transforming lactose, or the uncrystallizable sugar of milk, into dulcose or dulcine, the sugar of mannite, which may easily be obtained in very beautiful crystals, by the successive reaction of hydrochloric acid and sodium-amalgam.

Transactions of the Pharmaceutical Society.

MEETING OF COUNCIL.

August 2nd, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. EDWARDS, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Carr, Groves, Hills, Sandford and Smith.

The minutes of the last Meeting were read and confirmed.

A letter from the Privy Council was read, approving the appointment of Mr. Alexander Noble as an Examiner in Scotland.

The Report of the Finance Committee was presented, showing on the General Fund Account a balance in the Treasurer's hands of . . . . £1812. 14*s*. 3*d*.
And submitting for payment accounts, amounting to . . . . £679. 18*s*. 7*d*.

On the Benevolent Fund Account the Secretary reported that he had received the legacy of £19. 19*s*. from the executors of the late Mr. Charles Coles; a donation of £5. 5*s*. from Mr. John Davison; and subscriptions amounting to £6. 2*s*. 6*d*.; that the present balance in hand was £231. 6*s*. 1*d*.

Resolved—That the Report be received and adopted, and payments made.

The Report of the Benevolent Fund Committee as to applications for relief having been read, it was

Resolved—That it be received and adopted.

Mr. Hills said he had received a letter from a Mr. Norcott, asking him to bring before the Society the case of the suffering French chemists. Mr. Norcott stated in his letter that he had been applied to by M. Genevaix, the President of the Society which had been formed to inquire into the present condition of the pharmaciens of the Seine, and to give assistance to the most necessitous. This gentlemen stated that the persons referred to were in a very distressed condition; that twenty-three chemists' establishments had been destroyed, and nine tradesmen had been utterly ruined, and would be unable to recommence business without assistance. A credit of 40,000 francs had been opened with the Pharmacie Centrale for an advance for drugs and chemicals, and they sought the aid of their fellow-craftsmen of Great Britain. Mr. Norcott had applied to the Lord Mayor, and also to the Society of Friends, and had obtained £200 from the former, and £50 from the latter; and he had been also requested to apply to him (Mr. Hills) with a view of bringing the matter before the Pharmaceutical Society.

The President said he had also received a letter from Mr. Norcott, who called on him, and made a similar application.

After full discussion, it was decided that the Council had no power to apply the funds of the Pharmaceutical Society to such a purpose, and the President was requested to communicate the same to Mr. Norcott.

A subscription list was, however, opened by several members of the Council for the purpose of rendering assistance.

The Report and Recommendations of the Library, Museum and Laboratory Committee having been read, it was—

Resolved—That they be received and adopted.

The Committee having recommended that the Report of each meeting of Council should be issued in the next following number of the Journal, it was

Moved by Mr. Sandford, seconded by Mr. Edwards, and

Resolved—That the Report of the Transactions of the Council be in future published in the next following number of the Journal, after the meeting of the Council, but that the Journal may, on those occasions, be issued on Saturday morning, instead of Friday as heretofore, if necessary.

Mr. Groves drew attention to a paragraph in Mr. Simon's Report to the Privy Council, a copy of which will be found at page 109 in this Journal.

The Report and Recommendations of the Parliamentary Committee having been read, it was

Resolved—That they be received and adopted.

Moved by Mr. Carr, seconded by Mr. Smith,—

Resolved—That the Registrar be instructed, and is hereby authorized, to erase from the register the name of Anthony W. Johnson.

On the Report of the "Special Committee appointed to direct the operations of the Society in communicating with the Local Secretaries and Members upon the subject of opposing the Bill" being read,

Mr. Betty said he desired to present the Report of this Committee and to wind-up the matter. They had prepared a scheduled list of the names of the towns, and the number of chemists and druggists in the district, as far as they could be obtained, with the number of signatures, and when the petitions were signed, in what proportion they were signed; also stating what Members of Parliament were communicated with, and in some instances the answers received from those gentlemen. He thought this might be published, and preserved for future reference as an index both of the feeling of the country on the matter and as a guide to action which might be hereafter taken. The number of petitions presented through the means of the Local Secretaries was 191. The first column showed the number of chemists canvassed in those districts, and the second column showed the number of signatures. The information, however, was not quite so full and complete as it might have been in all cases. But, with these exceptions, the returns might be considered very complete, and the general result was that five-sixths of those who were canvassed or asked to append their names to the petition had done so. He might also state that their action was not so thorough as had been anticipated at first, as there had been spontaneous action taken in many places, and other agencies at work, by means of which 107 other petitions were presented to the House of Commons from country Associations. For instance, in Manchester they only had 135 signatures out of 359 who were entitled to sign: but there were two or three other petitions from Manchester, which would account for the circumstance. He did not know that the Committee had anything else to report, but he wished to ask permission of the Council that the letters received by Local Secretaries from Members of Parliament and forwarded for the information of the Committee should be returned to them, with an expression of the thanks of the Council for their prompt and ample replies to the circular.

The President said the names of many of the towns, with the numbers of the signatures, had been already published in the Journal.

Mr. Betty said a complete list had not yet been printed, but the whole need not be republished. Still, he thought it would be well to publish a *résumé*, and also to state the fact that 107 other petitions had been presented, showing the feeling of the country on the subject.

Mr. Sandford asked if the list were perfectly accurate with regard to the first and second columns.

Mr. Betty said the committee had been bound by the returns of the local secretaries themselves, and he had gone through the addition of the different columns twice and believed it to be correct.

Mr. Sandford said he understood that in the case of Bristol, the figures of the first column had been omitted in the published report of the return.

Mr. Betty said the number put down in the first column was 100 and the number of persons who signed was 45; seeing that so few signed the Bristol petition he considered that there must be some error in the returns, especially as he had information from another source, and he thought he would make further inquiries before filling up the first number. He afterwards filled in the figures in pencil, not having a pen and ink at hand, and he supposed the printer did not feel himself justified in adopting them. He intended to write to Mr. Stoddart and explain the matter.

Mr. Groves said with regard to the value of these petitions, he might mention one instance. He asked a local secretary what he was doing in the matter, and was told that he had desired his young man to write letters to the local representative: but on beginning to argue the question with him, he confessed at once that he had not read the proposed regulations and knew nothing whatever on the subject.

Mr. Smith said he knew another case in which the petition would have been quite the reverse had the matter been properly explained.

Mr. Sandford said several such instances had been brought to his knowledge; in fact, he had a large mass of correspondence on the subject. The truth was that many who sent up petitions really never considered the amendments at all, but signed a petition against the Bill as it stood in its original form. There was not the same alacrity to publish the amendments which there was to publish the Bill.

Mr. Atherton said he did not see the object of this discussion.

The President said he did not think any notice should be taken in the Committee's Report of the petitions sent up irrespective of its action and through other channels.

Mr. Betty said he merely suggested it should be mentioned for general information; and really it referred to the same matter; and in several instances the Committee would have acted, but found they had been forestalled.

Mr. Edwards did not think they could regard what had been done by other parties.

Mr. Betty said he could easily effect his object by writing a private letter to the 'Journal,' stating the fact. He merely wished the members to be enlightened upon it.

It was then moved by Mr. Betty, seconded by Mr. Atherton, and

Resolved—That the letters addressed to Local Secretaries and others, forwarded to the "Special Committee for directing operations in connection with the late Pharmacy Bill," be returned to them by the Secretary, accompanied with the expression of the thanks of the Pharmaceutical Council for their prompt and ample replies to the Committee's circular.

Moved by Mr. Atherton, seconded by Mr. Betty, and

Resolved—That a copy of the foregoing resolution be forwarded by Mr. Bremridge to each Local Secretary.

REPORTS OF THE BOARDS OF EXAMINERS.

England and Wales.

July, 1871.

Examination.	Candidates examined.	Candidates passed.	Candidates failed.

Preliminary. One certificate was received in lieu of this Examination.

JACOB BELL MEMORIAL SCHOLARSHIPS.

The Board of Examiners reported that one Candidate presented himself for the Senior Bell Memorial Scholarship and thirteen for the Junior.

The Candidate for the Senior Scholarship failed to obtain the requisite number of marks for its award.

Of the candidates for the Junior Scholarship, three who had obtained more than the requisite number of marks were nearly equal, and, as only one Scholarship was granted in 1870, the Board recommended that the Council should give a scholarship to each of these three.

It was therefore

Resolved—That Junior Scholarships be awarded to

Robert Higgins Davies,
William Ashwell Shenstone,
and
Edward Rammell,

with free Laboratory instruction and materials for the Session 1871-72.

SESSIONAL PRIZES.*

The Board also reported that during the past Session sixty-seven Candidates had passed the Minor and twenty-three the Major Examinations in honours, of whom sixteen competed for the Prize of Books and four for the Pereira Medal.

On the recommendation of the Board, it was

Resolved—That the

PRIZE OF BOOKS

be awarded to Edward Rammell.

That the

PEREIRA MEDAL

be awarded to Henry Churchill.

The Professors presented their respective Reports of the results of the competition for the Prizes offered by the Council, which, having been read, it was

Resolved—That the following awards be made:—

CHEMISTRY AND PHARMACY.

Silver Council Medal .... Henry Churchill.
Bronze Council Medal .... Charles Arthur Overton.
Certificates of Honour ...... { Horace Davenport. / Thomas Iredale.
Certificates of Merit .... { Frederick J. Hanbury. / Walter Benjamin Cole.

BOTANY AND MATERIA MEDICA.

Silver Council Medal .... Henry Churchill.
Bronze Council Medal ...... Horace Davenport.
Certificates of Honour .... { Alexander Wood. / Walter Benjamin Cole.

Certificates of Merit ...... { Charles Arthur Overton. / George Bult Francis. / Thomas Iredale. / Herbert Charles Webb. / Charles Alexander Blake.

PRACTICAL CHEMISTRY.

Silver Council Medal .... James Hughes.
Bronze Council Medal ...... Henry Churchill.
Certificates of Merit ...... { Thomas Iredale. / Harold Woolley. / Herbert E. Constance.

An extra Silver Medal was granted to Arthur Percy Smith for the excellence of his replies to the questions set.

The Professor of Botany presented his Report on the Herbaria received in competition for the

BOTANICAL PRIZE,

and upon his recommendation it was

Resolved—That the following awards be made:—

Bronze Medal .... Wm. Walter Boycott Stoddart.
Certificate of Honour .. Augustus Horton Crundall.

Resolved—That the following being duly registered as Pharmaceutical Chemists, be respectively granted a Diploma, stamped with the seal of the Society:—

Bateman, John Montague .... Canterbury.
Cole, Walter Benjamin ...... Weymouth.
Davenport, Horace .... London.
Fegan, John .... Exeter.
Goodwin, Felix.............. Newark.
Hackett, John Henry .... Lincoln.
Holmes, Nathaniel Wheatcroft. Grantham.
Iredale, Thomas .... Leeds.
Parker, John Samuel .... Peterborough.
Stoakes, Benjamin Maidens .. Boston.
Tomkins, Henry .... Bedford.
Wilford, Josiah .... Newport Pagnell.

Resolved—That the following being duly registered as Pharmaceutical Chemists, be elected Members:—

Bateman, John Montague .... Canterbury.
Churchill, Henry .... Misterton.
Davenport, Horace .... London.
Fegan, John .... Torquay.
Iredale, Thomas .... Leeds.

Resolved—That the following Associate of the Society before July, 1842, be elected a Member:—

Eyre, Jonathan Symes ...... Launceston.

Resolved—That the following registered Chemists and Druggists be elected members of the Society:—

Field, Cornelius .... London.
Holme, Isaac Clayton .... Marple.
Kendrick, John, jun. .... Redditch.
Palmer, Enoch .... Great Grimsby.
Solomon, William Henry .... Stafford.

Resolved—That the following having passed their respective Examinations be elected Associates in Business:—

MINOR.

Slater, Jonathan .... Wells.
Tonks, Joseph .... Bewdley.

MODIFIED.

Humble, William .... London.

Resolved—That the following having passed their respective Examinations, be elected Associates of the Society:—

* The Sessional Prizes and Certificates will be distributed at the evening meeting on the 4th October next. Successful candidates will be expected to attend. An Address to the Students will be delivered by Mr. Mackay, of Edinburgh. Ladies are invited to be present.

MINOR.

Baldwin, Edwin	Bury St. Edmund's.
Banks, Edward	Salford.
Brown, George	Retford.
Collins, Martin Austin	Chertsey.
Cowgill, Brian Horatio	Manchester.
Dunn, Frederick Edwin	Uttoxeter.
Ellis, George	Southport.
Emson, William Nicholls	Dorchester.
Fortnam, Frederick Henry	Willenhall.
Heppell, James	Forest Hill.
Jones, James	Carmarthen.
Kirby, Frederick	Bridgnorth.
Knight, John Tomlinson	Nottingham.
Knowles, William Edward	Dewsbury.
Maddock, William Thomas	London.
Sandy, Frederick William	Strood.
Ward, John James	Newark.
Watts, Joseph, jun.	Attercliffe.
Williams, Joseph Bower	Olney.

MODIFIED.

Beattie, John	Edinburgh.
Greatrex, Henry	Dover.
Greenway, Charles M.	Ashby-de-la-Zouch.
Palmer, Henry Bridges	Ludlow.
Pierce, William George	York.
Powell, Edward Foley	Birmingham.
Wallis, Charles James	London.

The President said Mr. Vizer had written to the Secretary, referring to the proceedings at the late annual meeting, and asking for a copy of the notice by Mr. Giles of his intention to move an amendment.

After some discussion, it was resolved that Mr. Vizer be referred to the President, who was chairman of the meeting in question, for any information he required.

EXAMINATION IN LONDON.

July 28th, 1871.

Present—Messrs. Allchin, Barnes, Bird, Cracknell, Davenport, Gale, Garle, Haselden, Ince and Linford.

Forty candidates presented themselves for the Modified Examination; the following twenty-four passed, and were declared to be qualified for registration as

CHEMISTS AND DRUGGISTS.

Coker, Owen Cole	Pimlico.
Cooper, Birkett Nelson	Dewsbury.
Corrie, Andrew Adam	Bedford.
Cory, James Thomas Haines	Penge.
Cross, John	Southwark.
Greatrex, Henry	Dover.
Greenway, Charles Marriott	Coventry.
Gregson, Henry	Burslem.
Harwood, Charles	Manchester.
Hulbert, Samuel James	Chatham.
Humble, William	Hatcham.
Littlejohn, Alexander	Aberdeen.
Neale, Benj. Thomas Mills	Wellington, Somerset.
Parrish, Edward James	Bristol.
Pierce, William George	Gravesend.
Pigott, George Herbert	Tunstall.
Powell, Edward Foley	Birmingham.
Powell, Walter Aitken	Great Malvern.
Ray, William Herbert	Barnet.
Stenson, Joseph	London.
Stewart, William Henry	Paris.
Tate, Edward Pitt	Eastbourne.
Thompson, Frederick	Sheffield.
Wallis, Charles James	London.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The British Pharmaceutical Conference commenced its public proceedings at Edinburgh on Tuesday last by a Meeting at Craigie Hall, St. Andrew's Square. After the preliminary business (which we purpose reporting in a future number), the President, Mr. W. W. Stoddart, F.C.S., F.G.S., delivered the following address:—

Address.

Gentlemen,—The continued success of our Conference is a great cause for congratulation. Since our last meeting in Liverpool, when we had so large an accession of new members, we have to report a further increase of about 300, making a present total of 1878 on our books.

On thinking this over, one cannot help exclaiming, what a large amount of good ought to proceed from such an army of workers, if they have (as I hope they have) the welfare of pharmacy at heart! It surely must be impossible that any single member can remain indifferent to an acceptance of the great chance now offered to us, of improving the position, if not of ourselves, at any rate of our children and successors. I feel confident that most of us, if not all, will be persevering and steadfast in endeavouring to secure a solidity, an honourable value to the title of pharmaceutist, by combining a good scientific training with a sound practical knowledge.

I feel sure that my words will find an echo in the hearts of those who now bid us so hearty a welcome. We have been striving to cultivate the wish for advancement in many parts of England, and now for the second time we thus try to repay the warmhearted hospitality that we all know fills the breast of every true Scotchman. In the words of one of their own favourite poets I would say,—

> "When death's dark stream I ferry o'er,
> A time that surely shall come;
> In heaven itself, I'll ask no more,
> Than just a Highland welcome."

We are now sojourning in the land that produced such men as Thomson, Brewster, Murchison, Miller, Clyde, Leslie, Adam Smith, James Watts, Livingstone, Scott, Burns, and "John Mackay."

Pharmacy, in its true bearing, is one of the many offshoots of a scientific education, and cannot be properly cultivated and pursued without a fair acquaintance with several branches of natural science. Botany is, doubtless, an important study, yet chemistry must ever be our chief ally. We may accurately describe the characters of the Asiatic poppy, or the Peruvian cinchona, and yet be sadly at a loss if we knew not how to extract the morphia and quinia. All arts and manufactures are dependent on properly carrying out chemical principle. The miner would know nothing of the riches locked up in the solid rock if it were not for chemistry. Astronomy and microscopy would be an empty idea if the chemist had not prepared the appropriate glass for the lenses, or the alloy for their support. If this be true, how much more is the preparation of medicines dependent on chemical processes! How is it that so many of our extracts, infusions, and syrups are inert, while the plants from which they are prepared are so powerful and poisonous in their action on the animal economy? Why so many prescriptions oftentimes rendered valueless? Surely because the medicines have been rudely prepared, or, as not unfrequently happens, the prescriber brings together in the prescription substances that ought to be kept as widely apart as the poison cupboard and the retail department.

Those four wonderful elements, of which all organized bodies are composed, must be carefully tended and watched, and their several likes and dislikes known, before the pharmacist can elaborate the various medicamenta in their most perfect forms.

Those extraordinary glucosides, alkaloids and hydrocarbons that fill our shelves as truly point to the Divine originator of all, as do the mental and bodily powers of the man who measures and weighs, or the memory which gives him an experience whereby he can discriminate between the good and the bad, or the useful from the useless. In short, it is Nature, the visible agent of a munificent Creator that we must obey, and on her we are entirely dependent either in the field or in the laboratory. The labours of Dumas, Liebig, Frankland, Richardson, Hofmann, Odling, Williamson, Miller and a host of others, have brought to light by their experiments an array of facts so vast, that probably no one mind can grasp them all. We need only mention the compounds of ethyl, methyl and amyl, the chloral, pepsine and chloroform, to instantly call to mind what chemistry has done to alleviate the long list of "ills that flesh is heir to."

Oxygen, in its ordinary condition, and without the aid of moisture and heat, could not destroy the pestilent gases and organisms that abound in our crowded streets and courts; but, in its allotropic form, no sooner does it come in contact with the deadly impurities from our lungs and skin, or the emanations arising from our unnatural mode of living, than it immediately attacks the evil by destroying its very constitution, and prevents its poisonous influence on our health and comfort.

Can it be right, therefore, that so many of us should be from day to day in the midst of the various ozone-producing agents and recommending their use, and yet all the while not caring to know the why and wherefore of their friendly reactions?

This remnant of the dark ages of our pharmaceutical existence I fervently hope is, or soon will be, a thing of the past, and that our successors will make a better use of the advantages that science offers than their forerunners have.

To profitably carry on our businesses we must copy nature in all her operations. As in hers so in our own laboratories, nothing should be lost and nothing wasted. The pharmaceutist should strive as strictly to account for every atom or molecule in his transformations or substitutions as for the £. *s. d.* in his cashbook. Like all other callings, our own has arrived at its present state by very slow degrees; its foundation was laid on the alchemy of the Arabians and the empiricism of the Greeks. Its superstructure was built up *stratum super stratum* by the persevering study and steady observation of the inhabitants of Great Britain, France and Germany; while our American brethren have made a good start, and with their characteristic zeal have shown, by their various publications, a practical acquaintance with pharmaceutical operations. Let us, therefore, look after our laurels, and let it not be said by our children and theirs, that *we* have delayed our march on the high-road to knowledge. I cannot look around me at the present moment without the proud conviction that we have an earnest band of inquirers, who have met together at this our annual gathering for the purpose of receiving and imparting the results of their experience and observation. Variety is a common natural ordinance, quite as much so in ourselves as in the flowers of the field. The cry of "equality" which we sometimes hear, is a fatal delusion and the dream of a lunatic. We each must humbly play our own peculiar part in one harmonious whole. *Non omnes omnia possumus.*

Perhaps of all the discoveries which modern chemistry has introduced, the most marvellous are the methods of analysis and synthesis of the organic bases. It is true that we cannot produce in our laboratories the root of the madder or valerian, the sugar-cane or the Tonquin bean, but we can manufacture alizarine, valerianic acid, sugar and coumarin. No more startling proof of the advancement of synthetical chemistry can be adduced than the discovery alluded to by Mr. Perkin at the last meeting of the British Association, in his paper on the artificial preparation of alizarine.

Who could have supposed that there was the least relationship between two such dissimilar bodies as cinchona bark and gas tar; nay, more, that they should give rise to the same substance? Yet so it seems to be. You are, of course, all aware that the cinchona barks contain the alkaloids in combination with quinic acid ($C_7H_{12}O_6$), which is also found in the coffee, bilberry, holly, privet, oak, ash, elm and many other plants.

Thirty-three years ago Woskresensky, while experimenting on quinic acid, found that when it underwent oxidation, a peculiar yellow crystalline substance was the result, and to which he gave the name quinone ($C_6H_4O_2$).

$$\underset{\text{Quinic Acid.}}{C_7H_{12}O_6} + 2O = \underset{\text{Quinone.}}{C_6H_4O_2} + CO_2 + 4H_2O.$$

For many years the atomic constitution of quinone remained a disputed question, till the researches of Graebe showed that it was a substitution product from benzol, in which two atoms of hydrogen were replaced by two of oxygen.

$$\underset{\text{Benzol.}}{C_6H_6} + 3O = \underset{\text{Quinone.}}{C_6H_4O_2} + H_2O.$$

In 1869 Messrs. Graebe and Liebermann found out that from a compound of anthracene and quinine, both of which are present in coal-tar, was formed anthraquinonic acid, better known as alizarine. It is the first instance of a vegetable colouring matter being produced by artificial means.

An equally strange discovery has been made by Mr. Broughton, the Government quinologist, who has extracted carbolic acid from the *Andromeda Leschenaultii*, a plant growing freely on the Neilgherry Hills. It is said to be of far greater purity than that made from coal tar, but probably the cost of production will prevent its coming into general use.

Since we last met, pharmaceutical chemistry has lost an able investigator by the lamented death of Augustus Matthiessen, who, in conjunction with Messrs. Foster and Wright, was making a very considerable addition to our knowledge of the constitution of the opium alkaloids. For many years past these have been a complete puzzle, and never till now had we any light thrown upon the reason why the poppy capsule should contain such a surprisingly long list of different principles. Happily the experiments on the substitution products of morphia and codeia are being continued by Mr. Wright, who is assiduously working out the subject.

When either of these bases is treated with hydrochloric acid under pressure, an entirely new base is produced, called by its discoverer apomorphia ($C_{17}H_{17}NO_2$), and although it only chemically differs from morphia by the abstraction of the elements of water, it has the most opposite properties.

$$\underset{\text{Morphia.}}{C_{17}H_{19}NO_3} - H_2O = \underset{\text{Apomorphia.}}{C_{17}H_{17}NO_2}.$$

Apomorphia is remarkable for its powerful emetic qualities and unstable nature. The chloride, which is the salt most commonly used, is white and crystalline. Its freedom from all irritant properties renders it a valuable hypodermic agent. Only $\frac{1}{8}$th of a grain by the mouth or $\frac{1}{10}$th by subcutaneous injection acts with greater rapidity than any other emetic; indeed, it is the only one capable of being administered hypodermically.

When Codeia is acted upon under pressure by an excess of hydrochloric acid, a new base is separated, which the discoverers, Messrs. Matthiessen and Wright, called chlorocodide ($C_{18}H_{20}NO_2$).

$$\underset{\text{Codeia.}}{C_{18}H_{21}NO_3} + HCl = \underset{\text{Chlorocodide.}}{C_{18}H_{20}NO_2} + H_2O.$$

A further reaction then takes place, and the chlorocodide splits up into methyl chloride and apomorphia.

$$\underset{\text{Chlorocodide.}}{C_{18}H_{20}NO_2} = \underset{\text{Methyl Chloride.}}{CH_3Cl} + \underset{\text{Apomorphia.}}{C_{17}H_{17}NO_2}.$$

So that the curious fact appeared that codeia only differed from morphia by containing one equivalent more of methyl. Although, however, they obtained apomorphia from codeia, they were unable to reconvert apomorphia into morphia, and thus form morphia directly from codeia.

Dr. Hugo Schiff, of Florence, has announced that he has succeeded in artificially producing conia, the active principle in *Conium maculatum*. He says that when butyraldehyd is acted upon by alcoholic ammonia, dibutyraldin is formed.

$$\underset{\text{Butyraldehyd.}}{(2\,C_4H_8O)} + NH_3 - H_2O = \underset{\text{Dibutyraldin.}}{C_8H_{17}NO}.$$

By the dry distillation of the latter, conia, among other products, is eliminated, and may at once be recognized by its peculiar odour.

$$\underset{\text{Dibutyraldin.}}{C_8H_{17}NO} = \underset{\text{Conia.}}{C_8H_{15}N} + H_2O.$$

Mr. D. Howard has described a new cinchona alkaloid, which he detected by noticing an unusual loss when recrystallizing quinia. The new base is still under investigation, but seems to be nearly related to quinia, for its oxalate only differs by containing three more molecules of water. Chlorine and ammonia also produce the green colour and precipitate of dalleiochin, which is characteristic of quinia and quinidin. It differs, however, by the solution not being fluorescent.

Chloral hydrate appears now to have become a recognized addition to our materia medica as a good hypnotic. It may, however, be well to note that a comparatively large number of deaths have occurred from its use during the past year. In every case the fatal result has arisen from one of two causes,—either from an overdose, or else by the dose having been repeated too frequently, one having been swallowed before the effect of the previous one had passed away. A very remarkable instance of the latter recently came under my notice, and has been fully described by Dr. Norris in the *Lancet* (Feb. 28th, 1871). The deceased had taken 712 grains in nine days, 260 of which had been swallowed within 36 hours. Every part of the organs sent for analysis was preserved in the most extraordinary manner.

Not until 130 hours after death did the slightest odour of decomposition become perceptible. Chloroform was obtained plentifully from the tissues by distillation, after the addition of an alkali.

Professor Wurtz has stated to the French Academy of Sciences, that the nitrate of strychnia, used hypodermically, is an antidote to the poisonous effects of chloral. I have not, however, seen a confirmation of this strange announcement.

In the *Ann. der Chem. und Pharm.* 1870, Mr. Lieber describes a very convenient method of detecting the presence of alcohol in chloroform or chloral hydrate. He effects this by warming the suspected sample in a test-tube with a little iodized potassium iodide, and afterwards potassium hydrate. If alcohol be present, crystals of iodoform will be deposited.

Anæsthetic agents are still the subjects of much discussion. Bichloride of methylene and nitrous oxide have been tried over and over again by their respective admirers, but the weight of evidence seems to be in favour of the latter. The bichloride has too frequently induced nausea, a most distressing accompaniment to its administration, while the nitrous oxide appears to give almost universal satisfaction. Not one fatal accident has happened, although, within the last twelve months, it has been in daily use by dentists.

At a late meeting of the Medical Society in London, Dr. Richardson introduced metachloral, a singular isomer of chloral, and decomposable also by alkalies into chloroform and formic acid, but physically differing by being completely insoluble in either water, alcohol, or ether. It is a white greasy powder, which may be reconverted into soluble chloral by being heated to 180° C.

One of our esteemed corresponding members, Dr. Flückiger, has noticed an interesting property of oil of peppermint. When shaken with nitric acid, the oil exhibits a magnificent greenish-blue fluorescence. This hitherto undescribed phenomenon is extremely beautiful, especially when the electric spark is passed through it by means of the ordinary vacuum tube. The doctor remarks that, unfortunately, it is not a true test for the purity of the oil of peppermint, because other oils may be present without preventing the fluorescent appearance.

In a lengthy paper read at the Chemical Society, and reprinted in our Journal, Dr. Divers has made an important addition to our hitherto imperfect knowledge of ammonium carbonate. It appears that there are four varieties of this salt, having a simple relation to each other, and capable of crystallization from a solution, viz.:—

Normal Ammonium Carbonate,			$(CO_2)_2(H_2O)_4(NH_3)_4$
Half-acid	,,	,,	$(CO_2)_3(H_2O)_4(NH_3)_4$
Acid	,,	,,	$(CO_2)_4(H_2O)_4(NH_3)_4$
Hyper-acid	,,	,,	$(CO_2)_5(H_2O)_4(NH_3)_4$

Dr. Davies finds that by digesting these carbonates at a gentle heat with liq. ammon. fort., they become converted into ammonium carbamate ($NH_4NH_2CO_3$), thus furnishing a curious example of the dehydration of a salt in the presence of water. He agrees with Dr. Attfield, that the commercial ammonium carbonate is a compound salt of carbonic and carbamic acids, and is remarkably constant in its composition. Dr. Divers also states that, when ammonium chloride and calcium carbonate are heated together, as directed in the British Pharmacopœia, the product is not commercial ammonium carbonate. This is an after product during the refining.

New localities have been successfully tested for the cultivation of the poppy and cinchona plants. At the January meeting of the Pharmaceutical Society, a paper by Mr. Ward was read on a sample of Australian opium, collected in Gipps' Land, and sent to Mr. Hills for examination. It contained no less than 9 per cent. of morphia, so that the Australian climate may eventually prove favourable to the growth of the poppy plant.

In America, also, the production of opium has been tried as a profitable speculation. Mr. Wilson, of Vermont, has sown $6\frac{1}{4}$ acres of land with opium poppy-seed. From the resulting crop were gathered 640 pounds of opium, averaging 6·25 per cent. of morphia and realizing 10 dollars per pound.

In Ceylon the cultivation of the cinchona has attracted considerable attention. The analysis of a sample sent to England showed that each pound of the bark yielded 289 grains of sulphate of quinia, 47 grains of quinidine and 14 grains of cinchonine.

Last year, at the Liverpool meeting, Dr. C. Calvert called attention to some experiments he had been making on the composition of iron-rust. In our text-books the rust of iron is described as the hydrated peroxide of iron, with a trace of ammonia. The results of his analyses show, however, that rusted iron is a complicated compound of 93 per cent. of peroxide, 6 of protoxide, $\frac{9}{10}$ per cent. of carbonate of iron, $1\frac{1}{2}$ per cent. of silica, with a trace only of ammonia. Dr. Calvert finds that the idea of iron rusting from the presence of moist oxygen is entirely wrong. A long series of experiments proved that neither moist oxygen nor moist or dry carbonic acid, *separately*, had any action on iron, but that *a mixture of both* acted very energetically. Carbonic acid is the agent that determines and promotes the oxidation of iron, and not oxygen or aqueous vapour. This explains the curious fact that the presence of alkalies or their carbonates will prevent the oxidation of iron.

Our excellent Secretary, Dr. Attfield, with his usual aptitude for the practical application of his favourite science, has given an exhaustive paper on a proposed new nomenclature for universal adoption in future editions of the Pharmacopœia. The continual changes that have hitherto taken place, and the consequent increase of synonyms, are often a cause of much perplexity to the dispenser. I hope that the doctor's suggestions may be fully considered by future compilers of the next editions of our own, as well as those of other countries. We should then be unanimous, and travellers would have less difficulty in getting their prescriptions prepared.

In the provinces, Pharmaceutical education is gaining ground more and more. Papers read at meetings of the several Associations throughout the country, show that private study and the number of students are rapidly increasing.

In America, pharmacy seems to be prosecuted with more than usual vigour. They seem determined, in that part of the world, to fulfil the words of one of their poets, when he told them that—

"Though before you mountains rise,
Go ahead!
Scale them certainly you can,
Let them proudly dare the skies;
What are mountains to a man?"

At the December meeting of the Philadelphia College of Pharmacy, Dr. Maisch made an important communication respecting the solution of acetate of morphia and other alkaloids,—a subject, however, that had previously been alluded to by one of our members, Mr. Martindale, of University College Hospital. When the ordinary solution has been kept for some time, it becomes greatly altered in appearance; a myceloid growth rapidly forms and a brown matter is deposited, mixed with crystals. Analysis showed these latter to be the pure alkaloid without a trace of any acid. It is singular, also, that the solution of ammonium acetate decomposes and has eventually an alkaline reaction.

Those of us who have been accustomed to peruse the foreign publications must have painfully missed those from Paris. The horrid transactions and frightful display of human depravity, must have rendered scientific research impossible. We heartily sympathize with our Gallic brethren and reiterate the advice given by Horace to his friend Tibullus:—

"Inter spem curamque, timores inter et iras,
Omne crede diem tibi diluxisse supremum.
Grata superveniet, quæ non sperabitur, hora."

I must not, however, trespass longer upon your patience, although many things that have transpired during the past year might be profitably recalled to our memories. In the present day we, as Britons, must put forth our best energies, lest we fall into the rear of intelligent nations. Our young men are justly, though tacitly, making an urgent appeal for our help. We do not, of course, press them to join our ranks; but when they ask to be admitted and we do receive them, we are not doing the thing that is honest, if we fail to show the greatest solicitude for their welfare. The act of taking a pupil or apprentice is now one of very grave responsibility. When we sign an indenture we there and then become answerable for the proper education of that pupil, either by personal supervision or by securing the services of some substitute. Nay, I go further; my own impression is, that no one ought to take a pupil unless fully competent to answer most of the many questions that crop up in the mind of an earnest student, or else to show him how to get the desired information.

On the other hand, I think that a lad who has not received a good solid education, is not the one to be a Pharmaceutical pupil. His time then becomes too valuably occupied to be wasted in procuring the exceedingly little knowledge requisite for passing the Preliminary examination. We often hear it said that a youth has a good education because he is tolerably conversant with Colenso and Morell. This is a very common mistake. It is not education. Professor Huxley has justly reminded such an one, that reading, writing and arithmetic are only the means whereby we are enabled to open the educational casket.

I am fully conscious that I am addressing many to whom these remarks are superfluous, but the letters that appear from time to time in our Journal too plainly evince the deficiency to which I allude. We ought not to rest satisfied with the sandy foundation of semi-ignorance, but steadily persevere in building our intellectual structure on the rocky basis of observation and experience.

Appropriate food is as necessary for the mind as it is for the body. If we choose to feed our mental powers on the trashy material that is often miscalled literature, we cannot expect to have a healthy appetite for that which is good and worth remembering. What is it that prevents so many of us feeling a delight in the researches of others, or searching for ourselves? It is nothing less than mental dyspepsia and intellectual debility. Example is far better than precept, and we cannot expect our pupils to acquire a keen relish for mental cultivation, or believe it to be necessary, if they see that we ourselves care so little, and become so apathetic.

It is no drudgery or hard work that I recommend, but a pleasant relief from the monotonous routine of a chemist's life. The test-tube or the microscope, the herbarium or the pencil, will soon enough reward the trial with the substitution products of pleasurable surprise and wonder; for—

"Labour with what zeal we will,
Something still remains undone;
Something uncompleted still
Waits the rising of the sun."

I cannot conclude without allusion to the indefatigable exertions of our secretary, Dr. Attfield. Few of you know what a debt is owing to him for the completion of our first Year-Book. Unforeseen and unavoidable difficulties arose, that postponed its issue till late in the season; and it is to his indomitable *esprit de corps*, and the editorial ability of Mr. J. Ince, that we are mainly indebted for that volume. I am sure, therefore, that you will allow me, in your names, to thank them heartily and sincerely.

It only remains for me now, Gentlemen, to thank you for having a second time placed me in the honourable position of your President. May success crown your endeavours, and may the advancement of true pharmacy be the guiding star of the British Pharmaceutical Conference!

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The general opening Meeting of this Association took place on Wednesday evening in the Music Hall, George Street, Edinburgh. Professor Huxley, the retiring President, having thanked the Association for the kindness he had received during his term of office, vacated the presidential chair in favour of Sir William Thomson, who then proceeded to deliver the following Address:—

Address.

For the third time of its forty years' history the British Association is assembled in the metropolis of Scotland. The origin of the Association is connected with Edinburgh in undying memory through the honoured names of Robison, Brewster, Forbes, and Johnston.

In this place, from this chair, twenty-one years ago, Sir David Brewster said,—"On the return of the British

Association to the metropolis of Scotland I am naturally reminded of the small band of pilgrims who carried the seeds of this Institutien into the more genial soil of our sister land." . . . . "Sir John Robison, Professor Johnston, and Professor J. D. Forbes were the earliest friends and promoters of the British Association. They went to York to assist in its establishment, and they found there the very men who were qualified to foster and organize it. The Rev. Mr. Vernon Harcourt, whose name cannot be mentioned here without gratitude, had provided laws for its government, and, along with Mr. Phillips, the oldest and most valuable of our office-bearers, had made all those arrangements by which its success was ensured. Headed by Sir Roderick Murchison, one of the very earliest and most active advocates of the Association, there assembled at York about 200 of the friends of science."

The statement I have read contains no allusion to the real origin of the British Association. This blank in my predecessor's historical sketch I am able to fill in from words written by himself twenty years earlier. Through the kindness of Professor Phillips I am enabled to read to you part of a letter to him at York, written by David Brewster from Allerly by Melrose, on the 23rd of February, 1831:—

"Dear Sir.—I have taken the liberty of writing you on a subject of considerable importance. It is proposed to establish a British Association of men of science similar to that which has existed for eight years in Germany, and which is now patronized by the most powerful sovereigns of that part of Europe. The arrangements for the first meeting are in progress; and it is contemplated that it shall be held in York, as the most central city for the three kingdoms. My object in writing you at present is to beg that you would ascertain if York will furnish the accommodation necessary for so large a meeting (which may perhaps consist of above 100 individuals), if the Philosophical Society would enter zealously into the plan, and if the mayor and influential persons in the town and in the vicinity would be likely to promote its objects. The principal object of the Society would be to make the cultivators of science acquainted with each other, to stimulate one another to new exertions, and to bring the objects of science more before the public eye, and to take measures for advancing its interests and accelerating its progress."

Of the little band of four pilgrims from Scotland to York, not one now survives. Of the seven first Associates one more has gone over to the majority since the Association last met. Vernon Harcourt is no longer with us; but his influence remains, a beneficent and surely therefore never dying influence. He was a geologist and chemist, a large-hearted lover of science, and an unwearied worker for its advancement. Brewster was the founder of the British Association; Vernen Harcourt was its law-giver. His code remains to this day the law of the Association.

On the 11th of May last, Sir John Herschel died, in the eightieth year of his age. The name of Herschel is a household word throughout Great Britain and Ireland —yes, and through the whole civilized world. We, of this generation, have, from our lessons of childhood upwards, learned to see in Herschel, father and son, a *præsidium et dulce decus* of the precious treasure of British scientific fame. When geography, astronomy, and the use of the globes were still taught, even to poor children, as a pleasant and profitable sequel to "reading, writing, and arithmetic," which of us did not revere the great telescope of Sir William Herschel (one of the Hundred Wonders of the World), and learn with delight, directly or indirectly from the charming pages of Sir John Herschel's book, about the sun and his spots, and the fiery tornadoes sweeping over his surface, and about the planets, and Jupiter's belts, and Saturn's rings, and the fixed stars with their proper motions, and the double stars, and coloured stars, and the nebulæ discovered by the great telescope? Of Sir John Herschel it may indeed be said, *nil tetigit quod non ornavit.*

A monument to Faraday and a monument to Herschel, Britain must have. The nation will not be satisfied with anything, however splendid, done by private subscription. A national monument, the more humble in point of expense the better, is required to satisfy that honourable pride with which a high-spirited nation cherishes the memory of its great men. But for the glory of Faraday or the glory of Herschel, is a monument wanted? No!

"What needs my Shakespere for his honoured bones
The labour of an age in pilèd stones?
Or that his hallowed reliques should be hid
Under a star-ypointing pyramid?
Dear son of memory, great heir of fame,
What need'st thou such weak witness of thy name?
Thou, in our wonder and astonishment,
Hast built thyself a live-long monument.
* * * *
And, so sepúlchred, in such pomp dost lie,
That kings for such a tomb would wish to die."

With regard to Sir John Herschel's scientific work, on the present occasion I can but refer briefly to a few points which seem to me salient in his physical and mathematical writings. First, I remark that he has put forward, most instructively and profitably to his readers, the general theory of periodicity in dynamics, and has urged the practical utilizing of it, especially in meteorology, by the harmonic analysis. It is purely by an application of this principle and practical method that the British Association's Committee on Tides has, for the last four years, been, and still is, working towards the solution of the grand problem proposed forty-eight years ago by Thomas Young in the following words:—

"There is, indeed, little doubt that, if we were provided with a sufficiently correct series of minutely accurate observations on the tides, made not merely with a view to the times of low and high water only, but rather to the heights at the intermediate times, we might form, by degrees, with the assistance of the theory contained in this article* only, almost as perfect a set of tables for the motions of the ocean as we have already obtained for those of the celestial bodies, which are the more immediate objects of the attention of the practical astronomer."

Sir John Herschel's discovery of a right or left-handed asymmetry in the outward form of crystals, such as quartz, which in their inner molecular structure possess the helicoidal rotational property in reference to the plane of polarization of light, is one of the notable points of meeting between natural history and natural philosophy. His observations on "epipolic dispersion" gave Stokes the clue by which he was led to his great discovery of the change of periodic time experienced by light in falling on certain substances and being dispersively reflected from them. In respect to pure mathematics, Sir John Herschel did more, I believe, than any other man to introduce into Britain the powerful methods and the valuable notation of modern analysis. A remarkable mode of symbolism had freshly appeared, I believe, in the works of Laplace, and possibly of other French mathematicians; it certainly appeared in Fourier, but whether before or after Herschel's work I cannot say. With the French writers, however, this was rather a short method of writing formulæ than the analytical engine which it became in the hands of Herschel and British followers, especially Sylvester and Gregory (competitors with Green in the Cambridge Mathematical Tripos struggle of 1837), and Boole and Cayley. This method was greatly advanced by Gregory, who first gave to its working-power a secure and philosophical foundation, and so prepared the way for the marvellous exten-

* Young's; written in 1823 for the Supplement to the 'Encyclopædia Britannica.'

sion it has received from Boole, Sylvester and Cayley, according to which symbols of operation become the subjects not merely of algebraic combination, but of differentiations and integrations, as if they were symbols expressing values of varying quantities. An even more marvellous development of this same idea of the separation of symbols (according to which Gregory separated the algebraic signs + and − from other symbols or quantities to be characterized by them, and dealt with them according to the laws of algebraic combination) received from Hamilton a most astonishing generalization, by the invention actually of new laws of combination, and led him to his famous "Quaternions," of which he gave his earliest exposition to the Mathematical and Physical Section of this Association, at its meeting in Cambridge in the year 1845. Tate has taken up the subject of quaternions ably and zealously, and has carried it into physical science with a faith, shared by some of the most thoughtful mathematical naturalists of the day, that it is destined to become an engine of perhaps hitherto unimagined power for investigating and expressing results in natural philosophy. Of Herschel's gigantic work in astronomical observation I need say nothing. Doubtless a careful account of it will be given in the 'Proceedings of the Royal Society of London' for the next anniversary meeting.

In the past year another representative man of British science is gone. Mathematics has had no steadier supporter for half a century than De Morgan. His great book on the differential calculus was, for the mathematical student of thirty years ago, a highly-prized repository of all the best things that could be brought together under that title. I do not believe it is less valuable now; and if it is less valued, may this not be because it is too good for examination purposes, and because the modern student, labouring to win marks in the struggle for existence, must not suffer himself to be beguiled from the stern path of duty by any attractive beauties in the subject of his study?

One of the most valuable services to science which the British Association has performed has been the establishment, and the twenty-nine years' maintenance of its Observatory. The Royal Meteorological Observatory of Kew was built originally for a sovereign of England who was a zealous amateur of astronomy. George III. used continually to repair to it when any celestial phenomenon of peculiar interest was to be seen; and a manuscript book still exists filled with observations written into it by his own hand. After the building had been many years unused, it was granted, in the year 1842, by the Commissioners of Her Majesty's Woods and Forests, on application of Sir Edward Sabine, for the purpose of continuing observations (from which he had already deduced important results) regarding the vibration of a pendulum in various gases, and for the purpose of promoting pendulum observations in all parts of the world. The Government granted only the building, no funds for carrying on the work to be done in it. The Royal Society was unable to undertake the maintenance of such an observatory; but, happily for science, the zeal of individual Fellows of the Royal Society and members of the British Association gave the initial impulse, supplied the necessary initial funds, and recommended their new institution successfully to the fostering care of the British Association. The work of the Kew Observatory has, from the commencement, been conducted under the direction of a Committee of the British Association; and annual grants from the funds of the Association have been made towards defraying its expenses up to the present time. To the initial object of pendulum research was added continuous observation of the phenomena of meteorology and terrestrial magnetism, and the construction and verification of thermometers, barometers, and magnetometers, designed for accurate measurement. The magnificent services which it has rendered to science are so well known that any statement of them which I could attempt on the present occasion would be superfluous. Their value is due in a great measure to the indefatigable zeal and the great ability of two Scotchmen, both from Edinburgh, who successively held the office of Superintendent of the Observatory of the British Association—Mr. Welsh for nine years, until his death in 1859, and Dr. Balfour Stewart, from then until the present time. Fruits of their labours are to be found all through our volumes of Reports for these twenty-one years.

The institution now enters on a new stage of its existence. The noble liberality of a private benefactor, one who has laboured for its welfare with self-sacrificing devotion unintermittingly from within a few years of its creation, has given it a permanent independence under the general management of a Committee of the Royal Society. Mr. Gassiot's gift of £10,000 secures the continuance at Kew of the regular operation of the self-recording instruments for observing the phenomena of terrestrial magnetism and meteorology, without the necessity for further support from the British Association.

(To be continued.)

Parliamentary and Law Proceedings.

HOUSE OF LORDS.

Petroleum Bill, *July* 26.—On the third reading of this Bill—

The Earl of Morley proposed an amendment, reducing the standard from 85° F. to 80° F. This he explained was consistent with safety, as the test would be made in a closed vessel, whereas it was at present made in an open vessel, and very variable.

Lord Cairns opposed the amendment, which was strongly objected to by the Metropolitan Board of Works.

The Earl of Morley, in deference to the noble and learned lord's objection, and in consideration of the late stage of the Bill, withdrew the amendment.

The Bill then passed.

HOUSE OF COMMONS.

Adulteration of Food, Drink and Drugs.—*July* 31.—Lord Eustace Cecil gave notice that, failing the action of the Government to bring in a measure to amend the law relating to the adulteration of food, drink and drugs, or to introduce clauses for that purpose in any sanitary Act which they may propose, he would, early next Session, again propose a resolution upon the subject for the consideration of the House.

Fatal Mistake at a Surgery.

An inquest was held at the Royal Exchange, Aston, on Thursday, July 27th, before Mr. W. S. Poole, coroner, on view of the body of a bricklayer's labourer, named Bullock. It appeared that a month ago deceased had fallen from a building upon which he was at work, and had fractured his ribs. He was attended by Mr. Hoare, surgeon. Deceased had so far recovered as to be able to walk from home, and on Wednesday morning had gone to the surgery of Mr. Hoare, and was given by Mr. Hoare a preparation called "linctus" for a cough, and another, a liniment, for external application. The latter mixture contained a deadly poison,—aconite,—and the deceased went on Wednesday morning (as mentioned above), taking with him his linctus bottle for the purpose of getting some more of the mixture. Unfortunately he did not see Mr. Hoare, but an assistant named Hunter, a young man about twenty years of age, who, instead of giving the linctus, gave the liniment. Bullock carried it home, and before the mistake was discovered had taken a dose, and two hours afterwards died. The inquiry is adjourned for a *post-mortem* examination to be made, and an analysis of the stomach.—*Aris's Birmingham Gazette.*

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Seeing *versus* Feeling and Hearing.

Sir,—I most cordially agree with the remarks made by your correspondent, Mr. M. J. Ellwood, in his letter published in the Journal of the 22nd inst. Respecting the addition of bells to bottles containing active poisons, a greater absurdity I scarcely thought a chemist would suggest. It is quite evident "Alarm Bell" (who suggested the addition of the bell) is not accustomed to an extensive dispensing or even a country trade, or he would have known that it is utterly impracticable. It may look exceedingly well, and do to show to his few customers what little confidence he has in himself or those about him. Allow me to inform him that in country towns the greater part of the business of the week has to be done in a few hours, and that country chemists have by far a greater number of prescriptions to dispense on the market days than all the rest of the week put together. And how pleasant for a nervous patient waiting whilst a prescription was being made up, on making the inquiry what that tinkling noise is on the tinct. opii, strychnia, or prussic acid bottle being touched, to be informed they contained poison! It would be sufficient, I imagine, to frighten such a person out of the shop. India-rubber bands, I am of opinion, would in a few weeks be entirely useless; and the india-rubber cap on market days would in all probability be thrown on one side till the throng was over. I would ask if the public has made any demand for regulations in the keeping and storing of poisons in chemists' shops? I have not yet been able to learn that they have, and it really looks very childish for an educated class of men like the chemists of the present day, to ask to be hampered with a set of regulations which would be of little use to those asking for them, who would, in all probability, be the first to break the law. Nothing can surpass or even equal those arrangements of poisons adopted by the proprietors of such establishments, for it is to their advantage to place them in such a position that they cannot be mistaken for some innocuous drug or compound, especially with Lord Campbell's Act hanging over their heads. I would suggest that every chemist should purchase a copy of that Act, and place it in a conspicuous place in the dispensing department of his establishment. Regarding the bottles before the trade for dispensing liniments, lotions, etc., a more unsightly and useless bottle I never saw than the "corrugated," without even a place to put on a label. The bottle I have adopted for some years now for liniments, lotions, etc. is the "fluted," made by the York Glass Company, which I have found to answer exceedingly well. But then I have had them brought for sweet nitre, almond flavour, etc., and when I represented what use the bottle was intended for, they wished to have what they required in the bottle, as it was such a nice one.

If those who have signed Mr. Sandford's letter have so little confidence in themselves, let them be under inspection by all means; but do not ask a respectable and great body of traders numbering some thousands, in whom the public has every confidence, to be subject to such an indignity. Surely the trade is not to be under the thumbs of Messrs. Sandford, Simon and Co.; or where has that privilege gone which hitherto has been an Englishman's boast—"liberty"? I do hope we have heard the last about the sale, storing and dispensing of poisons; and that the chemists of this country, who labour so long day after day, and are so poorly paid for their services to the public, will be allowed to carry on their business for the future in peace and quietness.

Hull, July 27th. Chas. B. Bell.

The Pharmacy Bill.

Sir,—It is surprising how prejudice and passion can blind the eyes even of large bodies of men, especially when these are aroused by selfish ideas of interest. I had not the honour of signing the letter addressed to members of Parliament printed in yours of the 22nd, but it has my hearty concurrence, and I shall use what little influence I may possess to thwart the ill-timed and ill-advised action of misguided men, who are factious agitators rather than members of an intelligent majority. I will not argue the question, for men who have written and acted as the opponents of the Pharmacy Bill are at present wholly insensible to argument or reason, for it would be like flaunting a red rag to a mad bull,—only infuriate them the more. They may have succeeded in stifling right feeling and calm judgment for the time, just as the manufacturers of Pennsylvania have imposed protection against the interests of America. So these short-sighted men are imposing a retrograde movement to the detriment of the best interests of the trade. But this will not last; "men will awaken;" the tyranny of petty dictators of the demagogue class, who have lately ruled the elections, and obtained a temporary majority, will be overcome. The calm sense of the Society will assert its supremacy, and we shall live to wonder that in the year of grace 1871 there could have been found amongst us obstructives as stupid as those who have opposed this Bill.

Because other nations are not free traders, therefore we will not have free trade, is an exploded argument. It is the same as saying, because medical men who keep open shop are not to be placed at once under these wise regulations, recommended by the whole Society for voluntary adoption, therefore we will not have them for chemists' shops.

If the regulations were wise,—and their adoption proves that the Society considers them so,—we should advocate their compulsory enforcement on all vendors of drugs, and include medical men, rather than say because we cannot achieve immediate and complete success therefore we will idly and negligently refrain from attempting any whatever.

I trust Mr. Sandford will not be swayed from his principles of duty by the senseless tirade against him. The approval of his conscience and judgment will shield him from these ungenerous attacks; and such terms as "treason," "treacherous," etc., will only recoil with tenfold force upon men who deserve the censure they give, and which the future will fix upon them.

Plymouth, July 29th, 1871. F. P. Balkwill.

Sir,—The desire expressed by you that agitation on the question of poison regulations should cease, after the withdrawal of the Pharmacy Bill from the present session, has evidently not been gratified. Now, although I have no wish to foster a spirit of antagonism in our Society, I must be permitted to say something in answer to your correspondents who have exercised their undoubted right of criticizing my conduct on this occasion.

A new light seems to have broken in on Mr. Schacht, who thought that chemists were all of one mind in reality, and all believed "each individual member of their fraternity to be competent to frame all requisite precautions for the safety of the public and the security of his own means of living." Did it never occur to Mr. Schacht that men may be competent and yet at the same time unwilling or indifferent? Does he not know that even in his own district a score of persons dealing in poisons may be found who take no precaution whatever, who keep tincture of opium and tincture of rhubarb side by side on their shelves, with no more difference than the ordinary label? Does he suppose that those gentlemen who framed regulations, and for two years upheld their imposition, deemed them unnecessary? And, again, does he not know that Mr. Forster over and over again stated that if compelled by want of time to withdraw the Bill this session, another would be introduced at the opening of next year; and that the general feeling of members of Parliament was that the Pharmaceutical Society had failed in its duty in not proposing compulsory regulations?

I regard "the success of the opposition," with which Mr. Reynolds opens, as nothing more than that transient success which often attends men who are prepared to talk against time; and I therefore feel that in the best interests of the Society, both those who deem regulations necessary and those who believe they will be forced on us, would do better to perfect those regulations, than to stultify themselves by saying, "we admit these rules to be good and practically adopt them, but will not recognize their universal establishment." I think in a former letter Mr. Reynolds said it would be illogical to accept the code even as "recommendations," if we declined to make it compulsory. He was perfectly right. I do not claim the sole honour assigned to me by Mr. Reynolds of issuing the circular to which I invited and received the signatures, and it would, perhaps, astonish him to read at least a hundred letters of most hearty concurrence which I have in my possession. He asks why I gathered together the names of about one hundred and twenty chemists. Simply because their names were at hand in the published list of local secretaries, and they had, many of them, sent petitions to Parliament against the original Bill. I deemed it right that these men should be put in full possession of the amendments to be proposed by Mr. Forster. Had time permitted, Mr. Reynolds knows well enough that I should have endeavoured, by the ordinary means set down in our bye-laws, to obtain a general meeting at which these amendments might have been fairly discussed.

Mr. Reynolds does sometimes indulge in hard words, and, "*speaking advisedly*," he says "the circular *dishonestly* assumes that its promoters were persons who recognized the faults of the original Bill." Having drawn a long bow for this insinuation, he naturally thinks of a "*treacherous arrow*"!

I forget whether Mr. Reynolds was present at the first Council meeting at which the Pharmacy Bill was discussed; if he was he may remember, and if he was not he may ascertain from those who were, that I was the very first person who drew attention to the objectionable part of the Bill, and that I was commissioned by my colleagues to communicate with the Privy Council and endeavour to obtain amendments. I can go even a little further than this and tell Mr. Reynolds that every amendment in the Bill was conceded most fully and fairly by the Privy Council, *with the approval of Mr. Simon*, on the representations of those gentlemen who went with me to amend, and not at the instigation of the opponents.

Having gone aloft on his arrow and gazed "with sorrow" (a little surprise also, perhaps) on the names of his adversaries, Mr. Reynolds deposits us in a "new cave of Adullam"; probably he would prefer the cave of Makkedah, for security's sake, for the names of good men and true, men long known to their brethren as zealous and faithful friends of the Pharmaceutical Society, appear on that honourable roll, and will still command the confidence and goodwill of their fellow-members, notwithstanding the charge of "*treason*" preferred against them by Mr. Schacht.

Sir, when I look back to the narrow majority which the non-regulationists obtained at the annual meeting, I think we may still claim to represent our constituents, and I pass by, as unworthy of notice, the charge of Mr. Reynolds that I am seeking "*by most questionable means and equally questionable allies*" to enforce my wishes.

I know Mr. Reynolds has strong views about representative government, and I know that he was the first to introduce electioneering tactics into our Society; a course of conduct which has deprived our Council of some of its best blood, and threatens to set up a state of intolerable terrorism, if we may judge by the correspondence which appeared in your columns last week between the Secretary of the "Chemists' Defence Association" and two members of Council.

I will only point to one other subject, because it is one on which a good deal of nonsense has been talked. Mr. Wade says he sees among the signatures the names of persons who formerly "*protested against any check that did not emanate from the brain.*" What can he mean by this? Is not the sense of touch as much a servant or sentinel of the brain as the sense of sight? And is it beneath the dignity of the brain to have impressions conveyed to it through the fingers? I commend 'Bell on the Hand' to Mr. Wade's careful perusal.

I am, Sir,

George W. Sandford.

47, *Piccadilly, August* 2, 1871.

Sir,—I rejoice with the majority of our fraternity that the Amended Pharmacy Bill has fallen (let us hope for ever). The Pharmacy Act of 1868 was pointed out by our great guns to confer immense advantages on the trade, instead of which it proves a snare; and in consideration of the innumerable advantages derived from that invaluable Act we were to be screwed down a little tighter. But, thanks to our Defence Associations, we have proved ourselves equal for the occasion. If it suits the fancy of a few West-End stars to erect elaborate poison cupboards, etc. etc., well and good; a very pretty ornament, no doubt; but let those alone who have no such mania; and, perhaps, in many cases cannot afford the expense of such useless furniture.

Having had some years' experience in good houses in different parts of the country, I can fully enter into the feelings of our provincial brethren in so strenuously opposing the Bill, knowing it to be utterly impossible (particularly in agricultural districts) to conform to such regulations, even were they proved necessary. I therefore trust, should occasion require, we shall be found ready to defend our rights against the caprice of 120 elects.

Islington. W. N. G. L.

[The following additional correspondence between Messrs. Smith and Hampson has been forwarded to us by those gentlemen, with a request for its publication. Mr. Smith has called our attention to certain orthographical errors in one of Mr. Hampson's letters to him, which errors likewise occur in the copy received by us. The letters are therefore printed exactly as forwarded to us by each gentleman. In the copies forwarded by Mr. Smith, the letters of Mr. Hampson are preceded by a list of the officers and committee of the Chemists' Defence Association.—Ed. Pharm. Journ.]

(Copy.)

"*The Chemists' Defence Association,*
"63, *Piccadilly, Manchester, July* 25*th*, 1871.

"Sir,—I am obliged for the prompt acknowledgment of my note, and, as your reply contains several important misconceptions, it is necessary for me to trouble you with another letter.

"Let me, in the first place, disabuse your mind of the mistaken notion that the Chemists' Defence Association has assumed any kind or degree of authority over the members of the Pharmaceutical Council, such authority resting only with the constituents. It has not, therefore, attempted to exercise any authority over you; neither has the Association presumed to call upon you to resign your seat at the Council. The letters I have written to Mr. Carr as well as to you are my own personal acts, and in no way authorized by the Association. I am at a loss to discover in my letter the imperious tone of which you complain.

"I simply call your attention to statements in reference to your nomination, about which, viewed in the light of your subsequent action, there hangs an unpleasant mystery.

"Your friend Mr. Carr vouched for your opinion in his letter of March 14, 1871, on the question of the hour, hence your name was included on the popular list, and this undoubtedly conduced to your election.

"Can you wonder that there is much astonishment and some indignation manifested by many members of the Society who voted for you, when they found you voting in a most unexpected and incomprehensible manner, and directly opposed to the views they presumed and believed you entertained?

"If, with others, I have been so erroneously attributing to you 'a change of opinion respecting poison regulations,' it is a very pardonable mistake, when I had the authority of Mr. Carr's letter implicitly fixed on my mind.

"The only moral that I and others may gain from this unpleasant experience is, that when the prosperity and safety of the Pharmaceutical Society and the freedom of the trade are at issue, it will be well, at any future election, to be certain of the sentiments of those who are to be entrusted with the power of representation.

"I am, Sir, your obedient servant,

"Robert Hampson,

"E. Smith, Esq. "*Hon. Sec.*"

(Copy.)

"8, *The Strand, Torquay,*
"*July* 28*th*, 1871.

"Sir,—Your letter of the 25th inst. reached me only yesterday the 27th, just as I was leaving home, and I did not return in time to reply the same day.

"I cannot but express my great surprise to find that your letter of the 21st was 'your own personal act, and in no way authorized' by the Chemists' Defence Association. It seems to me that this is a very awkward way out of a very awkward position.

"The very first paragraph of your former letter distinctly says, 'the members of the Chemists' Defence Association have expressed surprise and indignation;' moreover, the words Hon. Sec. are attached to your signature. Surely, had the letter not been intended as an official document, there could have been no meaning in attaching these words to your name nor in heading your letter with 'the Chemists' Defence Association,' as well as with a list of executive committee; neither could there have been the smallest necessity for saying a word concerning the surprise and indignation of the members of your Association.

"It is not difficult to see that if I had been constituted of that plastic material of which dummies and delegates are commonly made, the Chemists' Defence Association would have proved itself pretty identical with its Hon. Sec.; but now, the Association finding itself in a false and untenable position, is anxious to place the onus of its false step on the shoulders of its unfortunate Hon. Sec.

"Need I point out, Sir, how neatly you have impaled yourself on the horns of a dilemma? Either your former letter was authorized by your Association or it was not. If the affirmative be true, then you stand convicted by your second letter; but if the negation be true, then as an honourable man and a gentleman you are bound promptly to withdraw the letter, with its misleading official appendages, and tender a suitable apology.

"I must remind you that I before refused to enter into correspondence, simply because you were acting as the representative of an Association having no authority, and consequently no *locus standi*, and for this very same reason I am still unable to correspond with you touching the other matters alluded to in your letters, so long as the words Hon. Sec. are appended to your name, or your communications headed with a list of some self-constituted committee.

"I again repeat my readiness and willingness to reply to any courteous communication from any gentleman.

"This correspondence will be published.

"Yours,

"EDWARD SMITH.

"R. HAMPSON, Esq., *Hon. Sec. to the "Chemists' Defence Association."*

"*The Chemists' Defence Association,*
"63, *Piccadilly, Manchester, July 29th*, 1871.

"Sir,—The false issue you attempt to raise in your letter of the 28th inst. is both evasive and irrevelent, and is scarcely worthy of notice.

"I distinctly affirm in my preceeding letter that this correspondence is strictly unofficial, or, in other words, that I have not been instructed by the Executive Committee either to begin or carry on this correspondence. Yet, to suit your own special purpose, you impugn the veracity and honour of the Executive Committee of the Chemists' Defence Association, and likewise my own, by calling in question my affirmations.

"I shall not reaffirm my statements, as it is of very little consequence whether you beleive or doubt them.

"In nearly all my correspondence in reference to matters pertinent to poison regulations I have used the printed notepaper headed with a list of the Executive Committee, and have signed myself Hon. Sec. Hence I used the same notepaper in writing to you.

"It is likewise *certainly true* that 'the members of the Chemists' Defence Association, *and those generally* who have opposed the enactment of further compulsory poison regulations, *have* expressed much surprise and some indignation at the support you have given to the members of the Pharmaceutical Council who are in favour of further legislative enactments of a restrictive character.'

"I simply stated this fact with others; as, for instance, the guarentee your friend Mr. Carr gave for your opinions on the poison regulation question, and your consequent appearance with him on the successful list, as an excuse *sufficient* for troubling you with my letter of July 21st.

"It appears, however, useless to continue this correspondence, as you are not disposed to give a gentlemanly credence to my statements; and as you show no willingness to assign any reason for voting contrary to the just expectations of the majority of the constituents who returned you to represent them on the Pharmaceutical Council at a most important crisis, I shall not therefore reply to any further communication you may make.

"I am, Sir, your obedient servant,

"ROBT. HAMPSON, *Hon. Sec.*

"E. SMITH, Esq."

(COPY.)

"8, *The Strand, Torquay, July* 31, 1871.

"Sir,—I have this morning received your note of the 29th.

"Yours,

"EDWARD SMITH.

"R. HAMPSON, Esq., *Hon. Sec.*
"*Chemists' Defence Association, Manchester.*"

THE COUNCIL OF THE NORTH BRITISH BRANCH OF THE PHARMACEUTICAL SOCIETY.

Sir,—Although very much occupied with the arrangements connected with the approaching Conference meeting here, I feel it would be unjust to myself and others did I not reply to a letter which appeared in your Journal on Saturday last, from Mr. Fairlie, of Glasgow, headed "The Council of the North British Branch of the Pharmaceutical Society."

I am the more disposed to notice this communication because I find something like a threat, or at all events a hope expressed, that at some future time the constitution and history of this Council may be discussed.

I understand that your correspondent has not been many months a member of the Pharmaceutical Society, which, to my mind, explains much of what he has stated; for, had it been otherwise, he must have observed, for many years past, that an Annual Meeting of the Society has taken place in Edinburgh, at which a Report from this very Council was read, approved, and sent to London for publication. At the same time, by the decision of these meetings, composed of town as well as country members, the Council for the next year was duly elected, as well as the other office bearers of the Society in Edinburgh. If Mr. Fairlie will take the trouble to obtain sight of a few of the back volumes of our Journal, he will find, usually in the May number, an account of those meetings, and a list of the gentlemen composing the Council, from which he will observe, that the oldest and best known pharmacists are among the number; and although we have, as he will see, been honoured more than once by the presence of some of our Glasgow friends at these very meetings, our regret has always been, that we have failed to induce more of our country friends to be present.

One word as to the origin of "the high-sounding title." In 1852, when the Pharmacy Act passed, there was a clause giving Edinburgh an examining body, with the same power and privileges as the examiners in London,—a fact which will be made apparent on reference to the proceedings already referred to, for one portion of the business each year was to nominate the members of the Board of Examiners in Edinburgh, and these were forwarded to London for confirmation by the Privy Council. The names comprising this Board will speak for themselves. At the time of the passing of this Act, and to enable the new machinery to be fairly set a-going, the late Mr. Jacob Bell very kindly paid Scotland a visit, and it was at his suggestion that the Council was elected, the name bestowed, and the operation of the North British Branch ever since continued. A museum and library have both been in existence since then, and belong to the parent Society, while the Council referred to have had funds regularly sent from London, with which to carry on the business of the Society in Edinburgh. In other words, the North British Branch of the Society here has always had a different position to that of any other local association in England, Scotland, or Wales, and will, I hope, continue to do so.

Pharmaceutically, Glasgow has been for many years asleep, and no one rejoices more than I do at the awakening which has taken place; and from whatever cause this has arisen, I can honestly say, go on and prosper. But, with all due deference to the energetic secretary of the West of Scotland Defence Association, I must ask him not to censure or insinuate where there is no real foundation for doing the one or the other. As previously stated, the name of the local Council here has been long known and its existence understood; and it must be distinctly remembered that there was no pretence made to mislead in regard to the opinion of this Council as to the poison regulations, beyond what was expressed in the minute, a copy of which, at the request of the meeting, I simply sent to London. JOHN MACKAY, *Hon. Sec.*

Edinburgh, July 31*st*, 1871.

H. Fölker.—There is little doubt that, as you suggest, the word is a misspelling of "Origanum."

A. Pickering.—We have received your letter, but we are unable, from want of space, to insert the communications of private individuals with Members of Parliament.

COMMUNICATIONS, LETTERS, etc., have been received from Dr. Procter, Mr. J. Borland, Mr. Fairlie, Mr. M. C. Cooke, Mr. Dymond, Mr. Leay, Mr. G. Harvie, Mr. W. H. J. Shaw, Mr. H. J. Walker, Mr. J. T. Jones, Mr. R. Newall, Mr. J. Thompson, Mr. J. J. Thomas, Mr. R. W. Giles, W. N. G. L., W. F. C., G. R. C., "Gramme."

THE PARIS SCHOOL OF PHARMACY.

BY WALTER HILLS.

In pursuing my short sketch of the School of Pharmacy in Paris I come now to the lectures, which are very numerous, and generally well attended. Although the admission is entirely free, as far as I was able to judge, very few besides the regular students in pharmacy availed themselves of this privilege, arising probably from the fact that the generality of knowledge seekers prefer the lectures given at the "Sorbonne," or the "Collége de France," where the range of study is more extended. For example, I find at the latter institution the following list for one day:—

Vendredi.

9 heures. Langue et littérature française du moyen âge.
10 heures. Philologie et archéologie égyptienne.
10 heures. Mécanique céleste.
10 h. ½. Physique générale et expérimentale.
11 heures. Economie politique.
Midi. Physique générale et mathématique.
Midi ½. Histoire de la médecine.
Midi ½. Langue et littérature grecque.
Midi ½. Histoire des législations comparées.
1 heure. Chimie organique.
1 heure. Médecine expérimentale.
1 h. 5. Langue turque.
2 heures. Histoire naturelle des corps inorganiques.
2 heures. Philosophie grecque et latine.

But to return to the less extended pleasure-grounds of the School of Pharmacy, we find that there are two lecture theatres, a larger of a semicircular shape, and seating perhaps 200 students, and a smaller, rectangular, capable of accommodating 100 or 150. In the first *semestre* of the student's year, the lectures are three per week of each of the following subjects:—

Physics. M. Buignet.
Inorganic Chemistry. M. Riche (agrégé of M. Bussy, director of the school).
Galenical Pharmacy. M. Chevallier.
Zoology. M. Milne-Edwards.
Materia Medica. M. Planchon.

In the second *semestre*, there are every week three of the following:—

Toxicology. M. Bouis.
Botany. M. Chatin.
Organic Chemistry. M. Berthelot.
Pharmacy (chemical division). M. Lecanu.

During the latter, which is the summer session, there are also herborizations about every other Sunday, in which any one may join. The rendezvous for these is generally at one of the railway stations at 7 or 8 o'clock A.M., or even earlier, and the professor of botany then accompanies the party to a district which he knows to be at that season particularly rich in plants of pharmaceutical interest. On some occasions this may be twenty or thirty miles out of Paris; but the railway companies grant tickets at a greatly reduced charge, so that it is not so great an expense as would appear at first sight.

It will be seen that the lectures are not deficient in number; and in quality, as far as I am able to form an opinion, they are excellent. I find that those on physics and botany extend over two sessions, and I must speak very highly of the former which are delivered so ably and fully by M. Buignet, whose course on magnetism and acoustics I had the pleasure and privilege of attending. M. Chatin treats of structural and physiological botany in the first session, and of systematic botany (taking the whole of the Natural Orders) during the second.

Before concluding, I would draw attention to the great importance attached by the French professors of pharmacy to the subject of toxicology, to which, as may be seen, a whole course of some twenty-five to thirty lectures is entirely devoted. I believe that in France the *pharmacien* is generally regarded as the man from whom scientific aid is to be sought in all cases of poisoning, adulterations of food, etc., from the fact that he combines with pharmacy the study of chemistry proper; and I hope that the time will come when in England pharmaceutists, as a body, will in this respect merit their still higher title of "chemist," and that each member of our profession will be looked upon in his own town or village as the best authority in cases requiring analytical research. I think that the medical man who now often comes in for this work would gladly relinquish that which must sometimes interfere with his professional duties, and the chemist, with his apparatus and reagents always ready, might make this branch of his business in some degree lucrative, as well as a highly interesting study to himself and an advantage to his neighbours.

ETHEREAL SOLUTION OF QUINIA.

BY CHARLES RICE.

An ethereal solution of quinia has for several years been quite frequently prescribed by prominent physicians in Philadelphia and elsewhere, and I have been often requested, especially by physicians in the country, to furnish them a formula for its preparation. Although the different steps of the preparation are simple enough, yet I have repeatedly been informed of failures in the hands of others. In order to furnish to those who are not practical pharmaceutists or chemists, and also to those who have met with ill success, a formula for its preparation, I shall give below the full detail, which will enable any one to prepare it for himself.

The object of the solution is to administer the alkaloid subcutaneously, in which case a much smaller dose is required, and a more speedy action is obtained than when administered internally. The idea of the subcutaneous use of quinia naturally suggested itself to practitioners from the previous similar administration of other alkaloids, especially morphiæ sulphas; but the neutral sulphate of quinia not being soluble to any useful extent in water, and the use of an acid solution being accompanied by pain and often severe inflammation, it was necessary to employ the pure alkaloid. And, of all the different solvents, ether seems to have found the most favour.

By the way, I would remark that the practice of some apothecaries of using dilute sulphuric acid in their solution of morphiæ sulphas is highly reprehensible and denounced by physicians, on account of the pain and inflammation following its hypodermic use; water being all that is necessary.

Most authorities state that 1 part of quinia requires 60 parts of ether for its solution. This statement is quite correct, as far as the solution of the *dry* alkaloid is concerned, and it is by no means easy to prepare a solution even of that strength. But we may readily dissolve the quinia in ether, either at the moment of its precipitation from one of its salts, or at all events while yet in a moist state. The ethereal solution thus obtained may be concentrated to such a strength, that 2 minims of it will contain 1 grain (and even more) of quinia, although in this state the solution is too thick for use, and too liable to solidify. Hence quinia (recently precipitated and yet moist) may be said to be soluble in ether in all proportions, as has been stated already by Bussy and Guibourt (*Journal de Pharmacie et de Chimie*, vol. xxii. 1852, pp. 413, 414).

The strength of the ethereal solution, as employed by many practitioners, is such that 5 minims contain 1 grain of quinia.

Preparation.—Take 364 grains of sulphate of quinia, which has been (previously to weighing) deprived of its water by drying it at 212° F., mix it with 1 pint of water, and add to it just sufficient dilute sulphuric acid to dissolve it. Filter if necessary, and wash the filter carefully. Introduce the solution into a 4-pint bottle, and add sufficient water to make it measure 32 oz. The next step is to precipitate the quinia, and in order to avoid too great an excess of aqua ammoniæ, it is best to make a preliminary trial of the dilute sulphuric acid and aq. ammoniæ to be employed in the process. Introduce into a graduate 1 fl. oz. of the dilute acid, add some strips of litmus paper, and, while stirring, drop in very gradually from another graduate (or burette) aqua ammoniæ, until the litmus paper turns blue. The amount of aq. ammoniæ used is the quantity necessary to saturate 1 fl. oz. of the acid. Now pour upon the solution in the 4-pint bottle a little more than *double* the amount of aqua ammoniæ, corresponding to the amount of diluted sulphuric acid used, in order to precipitate the quinia; for it is not only necessary to neutralize the amount of acid added, but also the other equivalent already contained in the original sulphate of quinia. Immerse the bottle in ice-cold water to absorb the heat generated during precipitation. Have a sound and tightly-fitting cork ready, through which are passed two narrow glass tubes, one of them nearly reaching to the bottom of the 4-pint bottle, the other just penetrating the cork, and both cut off at an even height on the upper side. When the bottle has been sufficiently cooled, pour into it 15 fl. oz. of stronger ether, and shake; the quinia will be dissolved, and the contents of the bottle will arrange themselves in two transparent layers, the lower one an aqueous solution of sulphate of ammonia (holding a little ether and also a trace of quinia in solution), and the upper one an ethereal solution of quinia. Introduce the cork into the mouth of the bottle, keeping the finger on the orifices of the glass tubes, and invert the bottle. Hold it for a short time in a somewhat inclined position, to allow the watery solution adhering to the sides and bottom to drain down into the lower layer; then remove the finger, and allow the lower layer to flow off into a vessel placed below. As soon as the line of demarcation approaches the cork, allow the liquid to pass only very gradually, and, as soon as all the aqueous solution has run off, receive the ethereal solution in a 16-oz. graduate. Rinse the bottle with ½ fl. oz. of ether, and add it to the former. Allow the ethereal solution to evaporate in a warm place (110°–120° F.), until reduced to 2½ fl. oz. Remove it, cover it well to prevent further evaporation, and cool it to the temperature of 60° F. Then measure off into a weighed graduated tube (or minim graduate) 5 minims, and evaporate to dryness. Should there be no scales sufficiently accurate to indicate fractions of a grain, use an aliquot multiple of 5 minims, such as 50 minims, in which case, of course, you will have to divide afterwards again by 10. There will probably be found more than 1 grain of quinia contained in the 5 minims; hence it is now only necessary to dilute it with ether to the required strength. Let us suppose that the residue of 5 minims weighed 1¼ grains, and that our remaining solution measures 2½ fl. oz.; now in order to make the solution contain 1 grain in every 5 minims, we have the proportion:—

1 (grain req.): 1¼ (grains found) $=$ 2½ (fl. oz.): x (fl. oz. req.) whence $x = 3\frac{1}{8}$ (fl. oz.); hence we have to dilute the solution with stronger ether so as to measure $3\frac{1}{8}$ fl. oz.

The original amount of sulphate of quinia (364 grs.) employed contains 40 grs. of sulphuric acid, and 324 grs. of quinia:* now, if all the latter were to remain in solution, we should obtain (at the rate of 1 grain in 5 minims) 1620 minims, or 3 oz. 180 minims; but during the evaporation a portion of the quinia has attached itself to the sides of the vessels, and this should not be scraped into the solution, since it will not only fail to redissolve, but will generally produce a further separation of quinia.

It will sometimes occur that, on pouring the ether upon the precipitated quinia in the bottle, the latter absolutely (or nearly so) refuses to dissolve; this is owing to the presence of undecomposed solution of bisulphate of quinia, which seems to prevent the solvent action of ether. By adding a little more ammonia and shaking, the solution will at once take place. But too much ammonia must be avoided, since this gives a tendency to the ethereal solution to deposit the quinia in a short time; at least, such is my experience.

The quinia adhering to the sides of the evaporating vessel may be dissolved off by the aid of a little diluted sulphuric acid, and kept in solution for future use; its amount may be determined by drying and weighing the graduate together with the crust of quinia, and re-weighing it after its removal. Supposing the former weight is 1020 grains, the latter 1000 grains, the difference will be the quinia, 20 grains. Now as

$$324 \text{ (equiv. of quin.)} : 364 \text{ (equiv. of sulph. qu.)} = 20 : x$$
$$x = 22\tfrac{38}{81} \text{ or about } 22\tfrac{1}{2} \text{ grains of sulphate of quinia.}$$

The ethereal solution prepared according to the above directions must be kept in well-stoppered bottles, and should not be long exposed to light. I have kept some samples unaltered for over one year. —*Amer. Journ. Pharm.*

---

* The author's calculations are slightly incorrect. Crystallized sulphate of quinia must be heated to between 110° and 120° C. (230° and 248° F.) to lose all its water of crystallization, when it still retains 1 HO of constitution, its formula being $C_{40}H_{24}N_2O_4, HO, SO_3$, and its equivalent weight 373, containing 324 dry quinia and 49 HO,SO_3. (See *Amer. Journ. Pharm.* 1855, p. 243.) 364 grains sulphate of quinia, deprived of all its water of crystallization, contain, therefore, 316 grains dry quinia.—Ed. Amer. Journ. Pharm.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

LIQUOR PLUMBI SUBACETATIS.

Acetate of lead is boiled with water and oxide of lead, the latter in proportion rather larger than is expressed by the formula

$$Pb\,(C_2H_3O_2)_2\;3\,H_2O + Pb\,O.$$

The solution probably contains more than one compound; but practically it may be looked upon as a solution of oxide of lead. Its strongly alkaline reaction upon test-papers, absorption of carbonic acid from the air to form an insoluble carbonate, precipitation of an insoluble sulphate on addition of sulphuric acid, point to the relationship subsisting between lead oxide and the alkaline earths, baryta, strontia, and lime. Liquor plumbi gives insoluble precipitates with mucilage of gum-arabic, with astringent and colouring matters, and with a large number of organic and other acids. Consequently it can rarely be mixed with a vegetable infusion or tincture without causing turbidity. With tincture or wine of opium, for example, the precipitate which it causes consists partly of meconate of lead, partly of compounds of oxide of lead with the mucilaginous and resinoid matters of the opium. In consequence of this property, a solution of oxide of lead in acetate of lead is frequently employed in the preparation of crystallizable vegetable principles, to remove from their solutions the coloured foreign matters with which they are naturally combined.

In making the liq. plumbi subac. dilutus it is imperative to use distilled water only, and in no case is it proper to clear the solution by the addition of acetic acid.

LIQUOR POTASSÆ.

Four parts of carbonate of potash are dissolved in ten parts of boiling distilled water, and then three parts of slaked lime are gradually stirred in, the ebullition being continued for a few minutes. After standing a short time the clear liquor may be decanted. It should not be filtered.

$$2\,KHO + Ca\,CO_3 = Ca(HO)_2 + K_2\,CO_3.$$

[§ It does not effervesce when added to diluted hydrochloric acid. Mixed with an equal volume of distilled water, it gives no precipitate with solution of lime or oxalate of ammonia.] Good liquor potassæ ought to answer to the first of these tests, but the two latter are unnecessarily severe. [§ When it is treated with an excess of diluted nitric acid, and evaporated to dryness, the residue forms with water a nearly clear solution, which may be slightly precipitated by chloride of barium and nitrate of silver, but is unaffected, or but very slightly affected by ammonia.] These characters show the absence of all but traces of silica, sulphates and chlorides, and alumina.

Liquor potassæ contains 5·84 per cent. of KHO.

LIQUOR SODÆ.—Made in the same manner as liquor potassæ. It contains 4·1 per cent. of NaHO. The chemical equivalent of 5·84 of KHO is 4·16 of NaHO. These quantities will saturate the same amount of an acid.

MILK-ANALYSIS BY THE AMMONIA-PROCESS.

BY J. ALFRED WANKLYN.

The ammonia process, which Chapman, Smith, and myself applied to water-analysis in the year 1867, is available for a great variety of purposes. There is a very simple application to the analysis of milk, which I propose to describe on the present occasion.

In our little book on water-analysis, we gave the proportion of 'albuminoid ammonia' yielded by caseine as 7·6 per cent. As we remarked, we could not guarantee the absolute purity of the caseine employed for that determination. Recent experiments, however, do not greatly modify the result. Apparently, the number was given a little too high, 6·5 being more in accordance with my later experiments. Inasmuch as normal milk contains 4·0 per cent. of caseine, 100 parts of normal milk should give 0·26 part of albuminoid ammonia,' and such is the result of recent determination.

In order to examine milk by the 'ammonia process,' the following method of procedure may be adopted. The milk is first diluted to a convenient degree; 5 cubic centim. (or, preferably, 5 grammes) of milk are placed in a 500 cubic centimetre measure, which is filled up with water to the 500 c.c. mark; the milk and water being then well mixed up together, there results a diluted milk. This diluted milk is of such a strength that 1 cubic centim. contains 10 milligrammes of milk. For the analysis, 50 milligrammes of milk—*i. e.* 5 cubic centim. of the dilute milk—is a convenient quantity.

A tubulated retort, capable of holding about a litre, is charged with 400 cubic centim. of ordinary water of fair quality, such as, for instance, the ordinary river water supplied by the London water companies. Next, then, is poured into the retort 50 cubic centimetres of alkaline solution of permanganate of potash, made by dissolving 200 grammes of solid caustic potash and 8 grammes of crystallized permanganate of potash in one litre of water. The retort is then connected with a Liebig's condenser, by means of a small piece of wide india-rubber tube, and heated by means of a good-sized Bunsen lamp, the naked flame of which may be applied directly to the retort. Distillation then proceeds. The distilled water, as it comes over, should be tested for ammonia by the Nessler-test, in the manner about to be described, and by the time 200 cubic centim. have distilled over, will be found to be quite free from ammonia. This point having been arrived at, the 50 milligrammes of milk (5 cubic centim. of dilute milk) are introduced into the retort, which will then contain 250 cubic centim. of water, 10 grammes of potash, and 0·4 gramme of permanganate of potash. The distillation is then proceeded with as long as ammonia comes over, the ammonia being estimated by the Nessler test.

The measurement of ammonia by the Nessler test is managed as follows:—

A solution of iodide of potassium, saturated with biniodide of mercury, is first prepared thus:—35 grammes of iodide of potassium, 19·1 grammes of bichloride of mercury—are dissolved in less than a litre of water, heat being employed to assist the solution of the salts. It will be found that a slight excess of biniodide of mercury will remain undissolved—filter or decant so as to separate this small quantity of undissolved red iodide of mercury. (Should, through failure to have used the proper proportion of the salts, there be no excess of undissolved iodide of mercury, a little bichloride must be added, until the red precipitate begins to be permanent.) Add, then, either 120 grammes of solid caustic soda, or 160 grammes of solid caustic potash. Dilute the liquid with water to the volume of a litre, and this is the *Nessler reagent*. Before using the *Nessler reagent*, add about 5 cubic centims. of strong aqueous solution of corrosive sublimate, which will occasion a slight precipitate; decant off this precipitate, and the clear liquid is fit for use. This last addition of corrosive sublimate has for its object the rendering of the Nessler reagent sensitive.

Use of the Nessler reagent.—Into a cylinder made of colourless glass, and marked so as to be a 50 cubic centimetre measure, put the distillate which you desire to test for ammonia. Add $1\frac{1}{2}$ cubic centim. of 'Nessler reagent,' which will produce a yellowish-brown coloration. Observe the depth of the colour. On a white piece of paper, side by side with the cylinder containing this coloured liquid just mentioned, place a second 50 cubic centim. cylinder. Into this second cylinder put pure distilled water, and add to the pure distilled water some standard dilute ammonia liquid—as many measures of the standard ammonia as you judge to be requisite. Add $1\frac{1}{2}$ cubic centimetre of Nessler reagent—a coloration will result—compare the colour with the colour of the liquid in the first cylinder. If the colours are equal, write down the quantity of ammonia you have added, and that will be the quantity contained by the 50 cubic centim. of distillate. If the colours are not equal, make another trial with a different quantity of standard ammonia, and so on until you get equal coloration.

The strength of the standard ammonia is such that *one cubic centimetre contains* 1·100th *milligramme* of ammonia. It is made by dissolving 0·315 gramme of chloride of ammonia in one litre of distilled water, and then mixing that solution with nine times its volume of pure distilled water.

The operation of Nesslerizing, as it is called, that is, the operation just described, is not difficult, as the many chemists who are in the habit of practising it have abundantly testified. There are a few little points requiring attention; thus, a few minutes must be allowed to elapse before reading off the colour; the liquid must be cool, the distilled water must be very free from ammonia, etc. The distilled water used for Nesslerizing is best prepared by the operator himself. A fair river water being taken, is set to distil; at first ammoniacal water will distil over, but after a time water free from ammonia will distil, and this must be tested, and then carefully preserved for use.*

The following are some examples of milk-analyses by the ammonia process :—

Milk yielding 12·92 per cent. of solids, and 8 per cent. of cream.

	Quantity of Milk taken.	Quantity of NH_3 obtained.
Exp. I.	100 milligr.	0·27 milligr.
Exp. II.	50 "	0·13 "
Exp. III.	50 "	0·13 "

Milk which appeared to have been somewhat skimmed, but not watered. Solids, 11·42 per cent.

	Quantity of Milk taken.	Quantity of NH_3 obtained.
Exp. I.	50 milligr.	0·135 milligr.
Exp. II.	100 "	0·255 "

Slightly-watered Milk. Solids 10·20 per cent.

	Quantity taken.	Quantity of NH_3 obtained.
Exp. I.	50 milligr.	0·095 milligr.
Exp. II.	50 "	0·095 "
Exp. III.	100 "	0·022 "

Highly-watered milk. Solids, 6·18 per cent.

	Quantity taken.	Quantity of NH_3 obtained.
Exp. I.	50 milligr.	0·075 milligr.

Highly-watered milk. Solids, 8·10 per cent.

	Quantity taken.	Quantity of NH_3 obtained.
Exp. I.	50 milligr.	0·070 milligr.

Expressed in a tabular form :—

	Percentage Solids in Milk.	Percentage of Ammonia.
I.	12·92	0·27
II.	12·92	0·26
III.	12·92	0·26
I.	11·42	0·27
II.	11·42	0·255
I.	10·20	0·19
II.	10·20	0·19
III.	10·20	0·22
I.	6·18	0·15
II.	8·10	0·14

In order to translate these results into percentages of caseine contained by the different samples of milk, it has to be borne in mind that 6·5 parts of ammonia correspond to 100 parts of caseine. The ammonia, therefore, when multiplied by 100 and divided by 6·5, indicates the caseine. In conclusion, the ease and rapidity of these determinations may be referred to. In half an hour an analysis of milk by the ammonia process may be easily made.—*The Milk Journal.*

* For further details I would refer to the book on Water-analysis, by Chapman and myself.

THE MODERN ASPECTS OF THERAPEUTICS.

BY WALTER G. SMITH, M.D.

(*Concluded from page 106.*)

But the most decided step in this direction has been made by Drs. Crum Brown and Fraser, in their important papers "On the Connection between Chemical Constitution and Physiological Action" (1868-69). By introducing a known chemical change into the constitution of a physiologically active substance, without breaking up its molecule, they have shown that the physiological action of the substance may be completely altered, and, in fact, inverted in kind.

They have examined with great care the physiological action of the salts of the ammonium-bases derived from eight of the better known alkaloids, and their results lead to the suspicion that chemical *condensation* (*i.e.* susceptibility of addition) is in some way connected with physiological activity, and that saturated bodies (*i.e.*, whose condensation = °) are inert, or nearly so. Thus by the addition of iodide of methyl to the non-saturated base strychnia, the poisonous activity of that alkaloid is diminished at least 210 times, and a quantity of iodide of methyl-strychnium, containing 21 grs. of strychnia, can be given to a rabbit with impunity. These observations are of the highest value, though at present they must be considered as but foretastes of what is to come, and it is remarkable that almost immediately after, two French physiologists, MM. Jolyet and Cahours published results corresponding in almost every respect with those of Brown and Fraser.

Dr. Richardson has done good work in the field of anæsthetics in their chemico-physical relations, and he has brought out the curious and interesting fact that, in the alcohol group, the anæsthetic effect has a definite connection with the chemical composition of the alcohol, the anæsthesia rising in proportion to the number of atoms of carbon; for example, contrast the action of ethylic alcohol, containing C_2, with amylic alcohol, containing C_5. It is observed also that definite changes are produced by the addition or substitution of new elements or radicals, such as H, Cl, I, C_2H_5, etc., and when the chemical relationships between different bodies are more thoroughly understood, we may eventually be able to deduce *à priori* the physiological action of a body from its known chemical history.

Dr. Rabuteau, who has made many contributions to physiological chemistry, believes that he is justified by his investigations in propounding, as a general law, that "the metals are more active physiologically, according as their atomic weights are more elevated, or, what is the same thing, as their specific heats are lower," *e.g.* Na, K, and Tl. The diatomic metalloids conform also to this atomic law, but the monads, curiously, are governed by a law which is the reverse of this. Thus F, Cl, Br, and I, is the order of physiological activity of the halogens, and this is precisely the inverse order of their affinity for O.

These illustrations are, at least, sufficient to shadow forth the assistance, qualitative and quantitative, which we may expect from physical and chemical science, and warrant us in believing in a sure foundation for future therapeutics. It is true that the facts, as yet known, are mostly isolated and disconnected, but we may compare them to separate bricks which, though singly of little value and without cohesion, yet when cemented and fitted together, will form a firm and durable superstructure. The physiological school, headed by C. Bernard and Brown-Séquard, has done much to elucidate the action of some most important drugs, and it is likely that the doctrine of physiological antagonists will lead to practical results.

The different effects of remedies when introduced by different channels, the principle of the administration of smaller doses frequently repeated, and the potency of drugs over the vaso-motor nerves are all receiving a greater or less share of attention, and are exerting a wholesome influence on our habits and methods of prescribing.

Yet even with the most perfect knowledge of the chemical and other properties of drugs, we cannot satisfactorily judge of the influence which they exert on disease, unless we know, in any case of recovery in which medicine has been used, what share is to be assigned to the curative power of the organism itself. The evident importance of this inquiry was recognized by the Austrian School of Medicine for years before it attracted much attention in these countries, and we have now, at all events, learned that a large proportion of diseases, numbering some of the most formidable character, may get well without the use of any drugs whatsoever, or, in other words, they have a natural tendency to terminate in the restoration of health. This salutary change of doctrine is due in part to an examination of the undeniable results afforded by homœopathic practice, but largely owes its impetus to the improved state of physiological and pathological science. There is, however, some danger of being over-zealous in our respect for nature's operations, for the efforts of nature are not always of a benignant tendency, and what is called "expectant medicine" may sometimes prove but "a meditation upon death."

A more accurate knowledge of the real properties of drugs than we have hitherto possessed, lies at the root of all future progress, and the mode of its accomplishment claims attention at the outset. This will be best carried out by carefully conducted trials on *healthy* individuals, checked by collateral experiments on the lower animals, and on patients suffering from diseases whose diagnosis, general course, and variations, are tolerably well known. Hitherto it has been almost exclusively the custom to endeavour to acquire a knowledge of medicines by instituting trials with them in disease, a method which has borne little fruit in return for the labour bestowed upon it. To Hahnemann, in particular, before he was carried away by the delusion of infinitesimal doses, belongs the credit of actively pushing forward the proving of medicines on healthy individuals, recommended by Störck, Alexander and Haller, and it is strange that, with very few exceptions, no provings of worth have been made by other practitioners until very lately.

Within the last two years Dr. J. Harley has shown the value of this line of inquiry in his elaborate and searching work on the action of opium, belladonna, conium and hyoscyamus, in which he has done much towards defining our knowledge of the effects and uses of these ancient neurotic remedies.

One most important issue of the careful testing of drugs would be the better determination of the "sphere of action" of each medicine, for it is already well known that certain drugs affect particular organs and tissues, and I believe, with Dr. Rogers, that this significant fact of drugs possessing elective affinities for certain textures will occupy a prominent place in our future therapeutics. We have reason to believe that the physiological and therapeutical actions of medicines are very closely related, and it is probable that the modifications impressed by various diseased conditions will not so materially alter their sphere of action, as is sometimes supposed.

Another real gain from this probation of drugs would be the expulsion from the materia medica of a crowd of articles which only serve to keep alive the embers of polypharmacy, and to obstruct our advance towards a more rational system of therapeutics. If we accept, as we may safely do, the axiom that a drug, which produces no perceptible effects when properly tested on healthy individuals, will prove equally inert in disease, what a host of reputed medicines would be cast into deserved oblivion!

Before concluding, I wish to point out most emphatically that we should not allow ourselves to overlook the continued necessity for bedside observation in our admiration of the progress and prospects of the scientific departments of medicine. Though our theoretical knowledge were ever so perfect, yet clinical experience must always hold an important position to every true physician, and "it is to the experience of the mass of the profession that we look for the final establishment of doctrine and rules of practice." The most rapid and complete advances in science can never do away with the necessity for watchful observation, and "the nice adaptation of means to end can only be gained by experience." The past history of medicine should teach us not to be too hasty in condemning or ridiculing a line of practice which united and prolonged experience has approved, even if it be contrary to the received dogmas of the day, or be incapable of immediate explanation. Rational experience must and will keep its place. Let it by all means be reinforced and directed aright, but not trammelled, and clinical researches and empirical decisions must eventually prove the touchstone of therapeutical theory.

Keeping in view, then, that the three chief aims and objects of medicine, especially so far as concerns the non-professional public, ought to be the cure of disease, the prolongation of life, and the alleviation of physical suffering, we can sum up, in Sir W. Jenner's words, our gains in practical medicine, as resulting in "advances in knowledge, in the addition to the science of medicine of new facts, the elimination of supposed facts, the more correct appreciation of the bearing of old facts, and the application of this new knowledge to the advancement of the practical objects of the science."

And, though the discoveries of our own time naturally appear to us of greater importance than those of preceding ages, even the most incredulous will admit that we have reached a stage when ignorance is giving way to knowledge, hypothesis to facts, and that the time is approaching when we shall be able to free ourselves from the quicksands of uncertainty, and rest on the firm basis of knowledge and truth.

THE PHARMACY BILL.

MEDICAL SOCIETY OF LEEDS.

At the Meeting of the Medical Society of Leeds, held at the School of Medicine, on Wednesday, July 12th, 1871, Dr. Clifford Allbutt in the chair, it was resolved unanimously:—

"That the manner in which the Pharmacy Bill proposes to regulate by law the minute circumstances of the storing of powerful drugs, has been laid before this meeting, and this meeting considers that ample time should be given by Parliament to estimate to what extent it will infringe upon the privileges of the medical profession. Since the Bill would enforce in the dispensaries of many medical men certain danger-signals, as applied to powerful drugs, which would not exist in closed surgeries, increased danger to the public might result, and this meeting trusts that Parliament will refuse its sanction to the Bill as it now stands."

MEETING OF CHEMISTS AT LEEDS.

A Meeting of subscribers to the fund for opposing the late Pharmacy Bill was held in the Library of the Leeds Chemists' Association on Monday, August 7, 1871; Mr. W. Smeeton, President of the Chemists' Association, in the chair; it was unanimously resolved,—

"That the hearty thanks of this meeting are due and are hereby tendered to W. M'Cullagh Torrens, Esq., M.P., for his opposition to the late Pharmacy Bill."

"That the best thanks of this meeting are due and are hereby tendered to Edward Baines, Esq., M.P., Mr. Alderman Carter, M.P., W. St.-J. Wheelhouse, M.P., C. B. Denison, Esq., M.P., and J. Feilden, Esq., M.P., for the courtesy and attention with which they received the representations made to them of the objectionable character of the late Pharmacy Bill, and for the grounds which most of these gentlemen have given their constituents for believing that they would have opposed its second reading."

"That this meeting approves of the decision of the Chemists' Defence Association, and of the Metropolitan Chemists' Defence Association, to maintain their organization, and recognizes their past valuable services in protecting the best interests of the trade as giving them additional claims for continued support."

"That the best thanks of the meeting be given to Mr. Smeeton for presiding."

UNIVERSITY OF EDINBURGH.

The ceremony of "capping" graduates in the University of Edinburgh took place in the Music Hall, on Tuesday, August 1st.

Professor Macpherson, Dean of the Faculty of Law, presented the following gentlemen for the honorary degree of LL.D., and made a short statement of the principal claims of each to the honour.

Thomas Andrews, F.R.S., H.F.R.S.E., Vice-President of Queen's College, Belfast, and Professor of Chemistry in the Queen's University, for his investigation into the laws of the development of heat in chemical combination, researches on ozone and demonstration of the continuity of the liquid and gaseous states of matter.

Pierre Joseph Van Beneden, Professor of Comparative Anatomy in the University of Louvain, author of memoirs of great value in various departments of comparative anatomy.

W. B. Carpenter, F.R.S., M.D. Edin., Registrar of the University of London, for his various writings on physiology, investigation into the condition of the deep sea and services in the promotion of education.

Professor Challis, for a quarter of a century Director of the Cambridge Observatory and Plumian Professor of Astronomy and Experimental Physics.

Auguste Colding and James Prescott Joule, for their services to science in connection with the subject of the conservation of energy.

James Joseph Sylvester, late Professor of Mathematics at Woolwich, for his contributions to mathematical science.

George Gabriel Stocks, Secretary of the Royal Society, Lucasian Professor of Mathematics in Cambridge University, for his contributions to mathematics and physiology.

Allen Thomson, M.D., Professor of Anatomy in the University of Glasgow, for his writings on embryology.

W. Spottiswoode, F.R.S., Treasurer of the Royal Society and of the British Association, for his distinguished services in the cause of science.

G. E. Paget, M.D. Cantab., D.C.L. Oxon., President of the General Medical Council.

William Huggins, F.R.S., D.C.L. Oxon., eminent among those who have brought into prominence the application of spectroscopy to the stars, developing, with the aid of modern researches, the modes of observation initiated by Fraunhofer.

Jules Janssen, another eminent spectroscopist, who has devoted himself specially to solar spectroscopy.

John Peter Gassiot, F.R.S., distinguished for his researches in electricity, and for the interest he has manifested in the Observatory at Kew by his recent munificent endowment of its magnetic observatory.

Various other degrees were conferred upon gentlemen entitled to receive them.

Professor Bennett then delivered the concluding address. After alluding to various changes that had occurred since he last addressed the graduates in 1849, he described the education which the University provided for the medical student, and adverted to the important position to be held by him in the future, and the valuable service he might render to the State by assisting to diffuse sound knowledge on vital points concerning the health. Reference was made to the ignorance still displayed in these matters, in spite of the lessons taught by the scurvy and smallpox; and the speaker attributed the immunity from smallpox enjoyed in Scotland during the last few months to the vast advantage resulting from Government interference, and compelling the people against their will to take the necessary precautions. These and other examples show the utter uselessness of supposing that sanitary laws will ever be followed by the public as long as they remain ignorant of the rudiments of the knowledge necessary for the preservation of their own lives. Under the present system of education classical and literary studies, and the reading of imaginative works—including poetry and most histories and biographies,—may foster taste and lead to the cultivation of art and of all that supports the elegancies of life, but it keeps up a metaphorical mode of speech and inexactitude of language, which has descended to us from the earliest times. The ancients believed that life was an immaterial principle that might be added to or taken away from the body, as exemplified in the fable of Prometheus, who animated the marble statue with fire stolen from heaven. They thought that the mental faculties and feelings were seated in the internal organs of the body. Hence the terms, "vital spirit," "spark of life," and so on, while the heart, the liver, the spleen, the reins, and other viscera, are referred to literally or metaphorically, as so many seats of mental faculties or moral feelings. We talk of the emotions of the heart as representing a state of mind distinguished from the reasoning powers. This loose and vague kind of language renders those that use it upholders of all kinds of error. Indeed these are the class of persons everywhere most intolerant, because they are least capable of comprehending scientific laws and scientific evidence. Clergymen and most religious teachers are totally insensible to the errors and discrepancies of language they use in the pulpit, so that, when the scientific man takes his place in church, he is surprised at the ignorance of established truths constantly shown. While acknowledging the great services rendered by the clergy, he thought what incalculably greater good would they effect if, in addition to their actual knowledge, they were acquainted with what is known as to the laws of life, the causes of death, the proper means for averting disease, and the influence which the body and the mind exert upon each other. It were easy to point out how all professions and all ranks of the community might in like manner be benefited by a similar acquaintance with physiological truth. Women in all ranks of society should have physiology taught to them. It should be an essential subject in their primary, secondary, and higher schools. So strong were his convictions on this subject, that he esteemed it a special duty to lecture on physiology to women, and he found them most attentive and interested in the subject, possessing indeed a peculiar aptitude for the study, and an instinctive feeling, whether as servants or mistresses, wives or mothers, that *that* science contained for them, more than any other, the elements of real and useful knowledge.

The Pharmaceutical Journal.

SATURDAY, AUGUST 12, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

CHEMISTS AND THE USE OF STILLS.

OUR correspondent "*Aqua Destillata*" has drawn attention to the "Act to Prevent the Use of Stills by Unlicensed Persons," but the conclusions at which he has arrived can scarcely be borne out by facts, or by the simple meaning of the words of the Act in question.

He states that the Commissioners of Inland Revenue are in this case acting in direct opposition to the Legislature, but he should bear in mind that in the framing of revenue laws the Commissioners and the Legislature are practically identical.

In the case of old duties a Bill is not prepared for their protection, unless the Commissioners have had instances brought under their notice sufficiently numerous to convince them that the revenue is in danger, and then they prepare a Bill based on this experience which will, as they believe, remedy the defects in the law. These Bills are generally passed without opposition, because they are known to have originated with those responsible to the country for the equitable collection of the duties imposed by the Legislature.

In the case of new duties, the Government is certainly responsible for their imposition, but the Commissioners prepare the requisite machinery for their equitable assessment.

Now in the case under notice, the facts are simply these. The Act 6 GEORGE IV. cap. 81 expressly states that "*every* person in Scotland or Ireland not being a distiller, rectifier or compounder of spirits, who shall keep or use any still for the carrying on the trade of a chemist, or any other trade or business requiring the use of any still or stills, shall pay a licence of ten shillings per annum." The Act 9 & 10 VICT. cap. 90, extends the provisions of this Act to England, and in the first section the words used are; "For every excise licence to be taken out by every person, not being a licensed distiller, rectifier or compounder of spirits, or vinegar-maker who keeps or uses any still or retort, the sum of ten shillings."

It will be seen that in the latter Act the word *chemist* is omitted, but in the second section of this Act it is distinctly stated that all "previous clauses, matters and things contained in the said recited Act of the 6 GEO. IV. cap. 81, shall be applicable to this Act, and to the several provisions, clauses, matters and things in this Act contained, as fully and effectually as if the same had been repeated and reenacted in the body of this Act."

As stated by our correspondent, the Act 9 & 10 VICT. cap. 90, contains the following exemptions:—"1st. Stills may be kept and used for experiments in chemistry; 2nd. Stills may be kept and used by persons carrying on trade or otherwise for the manufacture of any articles other than spirits or spirit mixtures." It must not, however, be overlooked that although there are these exemptions, the Commissioners, in framing this Act, have been careful to strictly reserve to themselves full power of granting or withholding these indulgences; and if the two Acts are carefully read together, it will be seen that the words "may permit" really mean that the Commissioners, having full power to compel all persons keeping or using stills to pay the licence duty, they in their discretion may (as a privilege, but not as a right) permit stills to be used without licence in cases of purely chemical research, and in those trades in which articles other than spirits or spirit mixtures are manufactured; provided always that they can impose such restrictions for the protection of the revenue, as they may think proper for its security.

The last clause of the Act seems to imply that the Commissioners have not the power to grant such indulgences to persons manufacturing spirits or spirit mixtures. Spirit mixtures would certainly include tinctures and all other preparations of which alcohol is an ingredient, and consequently the indulgence could not be extended to pharmacists.

As a general principle it must be borne in mind that the Commissioners of Inland Revenue being solely responsible for the spirit duties, which now amount to upwards of ten millions per annum, are compelled to make all their regulations tend to this one object; and, as a governing body, they could not grant an indulgence to keep a still to a single pharmaceutical chemist—who in good faith would use it simply for preparing distilled water—unless they were prepared to grant a similar indulgence to every chemist in the United Kingdom, and at the same time were ready to undertake the responsibility of providing such a system of supervision that the stills should be used only for legitimate purposes.

WE have been favoured by several correspondents with copies of a paragraph taken from the *Pall Mall Gazette*, founded upon the sad occurrence reported at p. 138 of this Journal, and bearing the sensational heading of "The Necessity for Hanging a Chemist." We do not see that any benefit can accrue from the reproduction of such an article; but as a sample of the whole we cull the one statement that "scarcely "a week passes without a coroner's jury returning a "verdict of 'death by misadventure,' the 'misad-"venture' being that some blundering chemist has "poisoned a customer." Lamentable as such an accident may be, when it does occur, and desirous as every one must be to devise means for preventing its repetition, we do not think the attainment of such an object will be much assisted by the pen of a writer who is evidently either quite ignorant concerning the subject on which he writes, or else willing, for the sake of spicing an article, to make statements which are so grossly exaggerated. Neither should we have thought that in a journal which claims to be written by gentlemen for gentlemen so much would have been sacrificed to the necessities of smart writing.

In a Report of Mr. W. G. M'Ivor, the Superintendent of the Government Cinchona Plantations in British Sikkim, he says that the state of the plantations near Darjeeling is very unsatisfactory. The plants have not the luxuriant foliage of those grown in the south of India, and trees of equal height do not produce an equal amount of bark, the trees being of more slender growth and the bark thinner. The climate is very moist, being rarely free from rain, and seems admirably adapted for the growth of cinchona; but the trees appear to thrive for three years at most, and then to become diseased.

A prospectus has been issued of a "Beetroot-Sugar Company," which it is proposed to form for the purpose of developing the products of sugar beet grown in the United Kingdom in a similar manner to the industries which have been successfully carried on for many years past in different Continental countries. The capital proposed is £200,000 in 20,000 shares of £10 each, half of which shares are to be issued directly.

We learn from the *American Journal of Pharmacy* that the sale of spurious quinine, which is a counterfeit of that of Messrs. Pelletier, Delondre and Levaillant,* is still carried on extensively in New York. It is now supplemented by another fraud, in which sulphate of quinine is sold for sulphate of morphia. This is offered in original 1-ounce bottles, put up by a London house, the quinine label being removed by the impostor, and a sulphate of morphia label substituted.

The Committee of the London School Board appointed to draw up a scheme of education have sent in a report, recommending the teaching of science in primary schools.

Provincial Transactions.

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

On Monday, the 24th ult., a lecture was given at the rooms of the above Society, by Mr. E. Nuthall, the subject being "Sulphur." The lecturer began by treating of the natural history of sulphur, and the various methods of preparing and purifying the same; and, after noticing its leading chemical characteristics, passed on to the consideration of its more important compounds.

The lecture was fully illustrated by very striking experiments.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

On Tuesday, the meetings of the British Pharmaceutical Conference commenced in the Craigie Hall, No. 5, St. Andrew Square, Edinburgh. Mr. W. W. Stoddart, F.C.S., F.G.S., Bristol, President of the Conference, occupied the chair. About 100 members were present.

The President, in opening the proceedings, said,—Gentlemen, we will now commence the business we have before us; and in doing so I would just ask those who are present, who may be delegates from other Associations, to give in their names. The Associations in other parts of the country are working wonders, and we desire, in our own as well as their interests, to notice them as much as possible.

Delegates.

The following gentlemen, who attended as delegates from various societies, gave in their names as follows:—Brighton—Mr. Savage and Mr. Schweitzer; Bristol—Mr. Schacht and Mr. Stoddart; Liverpool—Dr. Edwards (also delegate from the Pharmaceutical Association of the Province of Quebec), Mr. Shaw and Mr. Mason; Hull—Mr. Bell and Mr. Myers; Manchester—Mr. B. Benger; Glasgow—Mr. Fraser, Mr. Davidson, Mr. Kinnimont and Mr. Fairlie.

The Meeting in 1872.

Mr. Schweitzer said: Mr. Savage and I have been deputed by the Brighton chemists to offer the Conference a hearty invitation to that town as its next place of meeting, and to state on behalf of the chemists there that they will do their very best to make you spend a happy time.

The President: It is only necessary for me to say, after the kind invitation which Mr. Schweitzer has brought us, and knowing that the British Association will meet at Brighton next year, that we shall be happy to hold our Conference in that town. Is it your pleasure that we accept the kind invitation?

It was unanimously agreed to accept the invitation.

New Members.

The President: You will see that the next business before us is the election of members. I have to state that in order to save time the Committee at a meeting last night elected sixty-four new members. It will be for the Conference to approve of what the Committee has done.

Honorary Members.

The President said: I think that now is the proper time to elect the honorary members. There are two gentlemen whose names we wish to add, and who are very well known. I mean, Prof. Maisch, America, and Dr. De Vrij, the Hague. We shall be highly honoured to have their names on the list. I therefore propose that they be added.

The motion was agreed to.

Annual Report.

Professor Attfield (one of the general Secretaries) read the annual report of the Committee as follows:—

The President and Executive Committee once more have to report to the members of the British Pharmaceutical Conference that during the past year the Association has largely increased in numbers, usefulness and general prosperity. Nearly two thousand names are on our books, each member has been presented with a copy of the Year-Book, and the Treasurer's statement shows a balance in hand of fifty pounds.

Meetings of the Executive Committee.—During the past year your Committee has held six meetings.

On October 5th, 1870, after some matters of detail relating to the Liverpool meeting had been disposed of, a formal vote of thanks was conveyed to the Chairman, Secretary and other members of the Liverpool Local Committee, for the judicious, liberal and successful manner in which they had advanced the objects of the Conference. Mr. James Collins was then appointed to give evening assistance to the Metropolitan Secretary, in keeping the books of the conference, issuing circulars and acknowledging subscriptions; the post being made tenable for one year at a salary of twenty-five pounds. Messrs. Carteighe, Groves, Hanbury, Ince and Stoddart, with Professor Attfield as Secretary, were reappointed a Committee to superintend the publication of the Year-Book of Pharmacy. At this meeting eleven candidates were elected to membership.

On December 7th, 1870, two long reports of business transacted by the Year-Book Committee, on October 19th and 20th, were read, discussed and adopted. The continued illness of Mr. Brough had rendered imperative the appointment, by this Sub-committee, of a joint editor, an office which Mr. Joseph Ince had, after some persuasion, consented to accept. The Executive confirmed the action of the Sub-committee. Arrangements were then made for the distribution of the Year-Book to members. Ten gentlemen were elected to membership.

On February 1st, 1871, the labours of Local Treasurers and the courtesy of London merchants, in conveying parcels of the Year-Book gratuitously, were duly recognized and recorded. Plans for obtaining an increased number of members with the view of securing sufficient funds to continue the publication of a Year-Book were introduced by the Secretary, and fully discussed. At a previous meeting the Executive Committee had accepted, with much regret, the resignation of Mr. John Cargill Brough, as editor of the Year-Book. The sad state of Mr. Brough's health rendering any resumption of editorial work impossible, invitations to apply for the appointment had been issued, and responded to by three gentlemen. After due deliberation, the Committee elected Mr. Charles H. Wood, F.C.S., to the vacant post. Mr. Daniel Hanbury, F.R.S., and Professor Attfield were requested to revise the list of gentlemen, societies, and journals, receiving presentation copies of the publications of the Conference. The financial position of the Conference was considered at this meeting. The following proposition was carried unanimously:—"That the cordial thanks of the Executive Committee be conveyed to Mr. Joseph Ince for his valuable services in editing, at a very brief notice and at much personal inconvenience, the 'Year-Book of Pharmacy for 1870." Fifty-three candidates were elected to membership.

On May 16th, 1871, the London Secretary reported on the distribution of the Year-Book, described the difficulty, labour and expense connected therewith, and proposed that in future the volume should be sent by post direct from the printers to each member who had paid the annual subscription (5*s.*) and sixpence in addition for postage (total 5*s.* 6*d.*). The Committee instructed the secretaries to carry out this plan during the succeeding year. The secretaries were empowered to issue a new form of nomination and a new specimen page of the Year-Book. The estimates of Messrs. Butler and Tanner for printing, and Messrs. J. and A. Churchill for publishing a second Year-Book, on terms similar to those under which that for 1870 was produced, were accepted. The report of the Sub-committee on presentation copies of the Year-Book having been read and adopted, a resolution was passed, "That a copy of the Year-Book shall be offered to each provincial pharmaceutical association having a library." A list of subjects suggested for research was laid before the Committee, and Messrs. Williams, Groves and Attfield appointed to revise the same before its distribution to members. Eighty-one gentlemen were elected to membership.

On July 5th, 1871, the secretaries reported that since the previous meeting of Committee the following documents had been posted to each of the one thousand eight hundred members:—(*a*) the list of subjects suggested for research, together with (*b*) two nomination papers, (*c*) a specimen page of the Year-Book, and (*d*) a letter requesting members to obtain candidates for election; another letter (*e*) and other invitation papers had been sent to four or five hundred gentlemen likely to join the Conference. The Annual Circular (*f*) relating to the General Meeting for 1871, and, an enclosure (on behalf of the Edinburgh Local Committee) of (*g*), a card of invitation to a Conversazione have also recently been forwarded. The Report of the Year-Book Committee relating more especially to the arrangement of matter in the Year-Book was received and adopted. At this meeting of the Committee one hundred and forty-eight gentlemen were elected members.

Finally, on July 31st, your Committee met in Edinburgh to arrange business for the present meeting, and to elect sixty-four members.

Number of Members.—It will thus be seen that as a result of the labours of your Committee, the efforts of local secretaries and the kindness of individual members, about three hundred new names have been added to our roll since we assembled last autumn. The total number of members is now 1917. From these figures, however, there must be deducted, losses by death, 8, resignations, 14, untraced removals, 6, and members whose subscriptions are more than two years in arrear, 11, —total 39. This gives an effective strength of 1878. The Executive Committee congratulates the Conference on this high number, but would urge on every member the importance of using his utmost efforts in obtaining recruits. The production of Year-Books, without intermission, can only be secured by the united contributions of at least two thousand members. A much larger number than this may fairly be anticipated as the objects of the Conference become more widely known and more fully appreciated.

Amongst those whom death has taken from us there occur the following:—Mr. Gissing, of Wakefield, whose name is appended to the original circular inviting gentlemen to join the Conference then about to be inaugurated at Newcastle-on-Tyne in 1863; Mr. Tuck, of Oxford, five of whose papers appear in our Transactions: —1, "Mistura Creosoti;" 2, "Iodo-hydrargyride of Potassium, and the Oxidation Tests for Methylic Alcohol;" 3, "Test for Methylic Alcohol when mixed with Ethylic Alcohol; 4, Detection of Methylic Alcohol in Chloroform, Ether, Sweet Spirit of Nitre and Sal Volatile;" and 5, "On Eschwege's Patent Wood Spirit;"—and Mr. Quiller, of London, a name well known in pharmacy.

The Bell and Hills Fund.—A second grant of ten guineas' worth of books has been made by your Committee in accordance with the intentions of the benevolent founder Mr. Thomas Hyde Hills. Fourteen appropriately-bound volumes of recent works, not already in their library, were presented to the Liverpool Chemists'

Association and duly acknowledged. A similar present will be offered to the library of the North British Branch of the Pharmaceutical Society.

The Year-Book of Pharmacy for 1871, the second issued, is in a forward state, indeed the editor has laid on the table the manuscript of the work. As soon as the proceedings of the present meeting can be reported, the whole of the volume will be placed in the hands of the printers and, when published, a copy forwarded by post to members.

The Financial Position of the Conference.—Lastly, your Committee would draw attention to the Treasurer's statement of accounts. Every liability for the eighth Conference year—July 1st, 1870, to July 1st, 1871—has been discharged, and there is a balance in hand of £50. This sum is less by £40 than that remaining at the end of last year, but several exceptional expenses have been incurred, hence your Committee hopes that the income of the present year will meet the expenditure; a result that will certainly ensue if members will kindly obtain additional subscribers.

The Treasurer in Account with the British Pharmaceutical Conference, 1870–1871.

Examined and found correct,
H. S. Evans, *London.*
J. F. Robinson, *Liverpool.*

Mr. Ainslie (Edinburgh) said: I have much pleasure in moving that the report be adopted. It must be very satisfactory to those gentlemen who have originated this Conference to find that its affairs are in such a flourishing condition. There have been a great many additional new members this year, and I trust that in the year that is coming we shall have a much larger number, so that they will be able to give the Year-Book of Pharmacy without loss. I think that the number which Dr. Attfield has intimated—2000—will be made up before the next Conference. I think it is a very great advantage to us to have that book on our library tables.

Mr. Fraser (Glasgow) said: I have much pleasure in seconding the adoption of the report. The sum of 5*s.* paid by each member seems to be a very small sum. I think it might be raised to 7*s.* 6*d.* Five shillings is a very small sum to get the advantages of the Society.

Dr. Attfield: There will be no difficulty in raising enough money if we get more members. It only requires an effort. I have never asked a gentleman to become a member who has ever refused to do so; on the contrary, I have been thanked by gentlemen whom I have informed that they would get a book so full of matter, specially interesting to them, for so low a sum. In my opinion, the question of raising the subscription need not be entertained for one moment.

The report was unanimously agreed to.

The President then read his introductory address, which will be found at p. 112.

Mr. Kemp (Portobello) said: When I say that I have listened to the address of our President with very great pleasure, I am sure I am only expressing the feeling entertained by every one present. I think we are under very great obligation to the President for the very able, clear and succinct manner in which he has noticed the many new and important advances in pharmacy, and sketched out for us important and interesting studies on these subjects. He has noticed in the course of his address the importance of practical pharmacy. The time was when pharmacists were content with mere practice—with mere routine. I think that has greatly given way, and that it is now admitted that if practical pharmacy is to arrive at anything like perfection it must have a scientific basis. The very fact of the existence of the Pharmaceutical Conference is an evidence that scientific pharmacy is now carefully studied; and I have only to point to the very large meetings we now have as a further proof of that. I cannot enlarge on the address; but I desire on the part of the meeting to express our very hearty thanks to the President for his most excellent address. I beg to move to that effect.

Mr. Young: I beg to second the motion which has been proposed by my friend Mr. Kemp. Mr. Stoddart has given us an admirable view of what has been done during the past year; and I am sure we are all very grateful to him for the excellent reflections contained in the concluding portion of his address. There is very much in what he said that in addition to the masters being fit to instruct their pupils, the pupils should be in a condition to be instructed by them. I will say no more, but simply express my great satisfaction at listening to the able address which has just been delivered.

Mr. Deane: It has been moved that a cordial vote of thanks should be given to our President for his very admirable address. It would be quite superfluous in me to add anything, and therefore I will not take up your time. I very cordially concur in the motion. It is a rare thing for us to have such an address given to us. I therefore put it to you, as a mere matter of form, to say if the motion is carried.

The motion was carried amid loud applause.

The President: I thank you all for the very cordial expression of your approval of the address. I can only say it is no work; it is a real pleasure to do anything for this Conference. It is really a work of love.

Professor WRIGHT, D.Sc., read the following paper on

THE OXIDATION PRODUCTS OF ESSENTIAL OIL OF ORANGE-PEEL (KNOWN AS "PORTUGAL").

BY C. R. A. WRIGHT, D.SC.,
Lecturer on Chemistry in St. Mary's Hospital Medical School,

AND CHARLES H. PIESSE,
Assistant Analyst in St. Thomas's Hospital.

PRELIMINARY NOTICE.

Through the kindness of Messrs. Piesse and Lubin, we have been enabled to examine a specimen of *pure* oil of orange-peel. As stated by Soubeiran and Capitaine, and by Dr. Gladstone, this oil consists principally of a hydrocarbon, hesperidine, boiling at 174°, and of formula $C_{10}H_{16}$. We found that the crude oil commenced to boil at 175°, and that 97·2 per cent. by weight came over below 179°; the remaining 2·8 per cent. was a yellow, resinous substance, not volatile without decomposition, sparingly soluble in alcohol even when boiling, but very soluble in ether. In water it was almost insoluble, but it communicated to it the bitter taste of fresh orange-peel. At 100° it was perfectly fluid, but did not entirely solidify even after standing some days at the ordinary temperature. After complete expulsion of hesperidine by long-continued heating to 100°, it was perfectly inodorous; it contained no nitrogen, and on combustion yielded numbers agreeing with the formula $C_{20}H_{30}O_3$.

Hesperidine is readily acted on by nitric acid; if undiluted a violent action ensues, a viscid, yellow, tarry substance being formed; but if diluted with its own bulk of water, nitric acid acts more slowly. By long-continued boiling, an inverted condenser being attached, the evolution of red fumes and carbonic acid is noticed for some hours, and then almost ceases; the hydrocarbon is then found to be converted into a brown resin, becoming very soft at 100°, but hard and brittle after cooling. This resin contains a large quantity of nitrogen, and is apparently formed from the original body by addition of oxygen and replacement of hydrogen by NO_2. Its examination is not yet completed.

By the action of stronger nitric acid on this brown resin, a yellow resin not softening at 100°, and containing less carbon and hydrogen, is produced. The formation of this body is accompanied by the production of much oxalic acid, and possibly of a nitrogenized acid, as the snow-white oxalic acid obtained after precipitation, as lead salt, decomposition by hydric sulphide, and several recrystallizations contained nitrogen, and gave numbers on analysis (as well as its silver salt) approximating to, but not agreeing very well with, those required by theory.

On heating 1 part of hesperidine with 30 of water, 1 of sulphuric acid, and 3 of potassium dichromate, a slow evolution of CO_2 is noticed. After some hours boiling with an inverted condenser attached, the majority of the hydrocarbon is apparently unattacked, but on distilling an acid distillate is obtained. This acid, converted into barium salt and silver salt, gave numbers indicating that the acid was essentially acetic. The barium salt also gave all the qualitative reactions of an acetate.

Sulphuric acid and potassium chlorate have a violent action on hesperidine, and produce a viscid tar not yet fully examined.

The PRESIDENT said that this short communication by Professor Wright was only another proof that he was working in the right direction. He seemed to have hit the nail on the very head. This paper accounted for the difficulty they had of preserving the essential oil of orange-peel. No doubt the changes referred to would go to explain the change essential oil of orange-peel undergoes.

Mr. HANBURY said he supposed the gentleman who read the paper had not found the source of this essential oil; whether it was got from home or abroad—from the bitter or sweet orange. He thought it would be interesting to know about that.

Professor WRIGHT said all he knew was that it was received from Piesse and Lubin, from abroad, and that it was as pure a material as could be made. He obtained the article from the firm referred to; but as to the nature of the orange from which it was derived, he was not acquainted with it.

Dr. ATTFIELD said that there were many gentlemen present who would feel as he did, that they should recognize the labours of Professor Wright, by thanking him for his paper. It was one of those gems of research as to which he thought they would be insulting the work of Dr. Wright if they alluded to the mere practical application of such a paper. The practical application of these matters was far lower than the research itself, and sure to follow in the ordinary course of events. As to votes of thanks to authors of papers, it might be well to wait till the end of the meeting, and then thank the authors all at once. Authors of papers themselves generally said that they were so abundantly gratified in making the researches, that they did not care much for the thanks, and were willing to put off to the end of the meeting any recognition of their services in this respect.

It was agreed to postpone giving thanks till the close of the meetings.

The PRESIDENT said that the next paper was one of great ability, on "New Derivatives from Codeia." He was sure that that paper alone would repay them for coming to Edinburgh to hear it.

Professor WRIGHT then read the following paper:—

NEW DERIVATIVES FROM CODEIA.

BY CHARLES R. A. WRIGHT, D.SC.,
Lecturer on Chemistry in St. Mary's Hospital Medical School.

By the action of hydrobromic acid (48 per cent. HBr), on codeia at 100° F., there is produced firstly a base containing the elements of codeia, where OH is replaced by Br; and by a further action two other bases, one containing one atom of oxygen less than codeia, the other having the composition of four molecules of codeia coalesced together, one of the 84 hydrogen atoms in the product being replaced by Br.

Codeia	$C_{18}H_{21}NO_3$
Bromocodeide	$C_{18}H_{20}BrNO_2$
Deoxycodeia	$C_{18}H_{21}NO_2$
Bromotetracodeia . . .	$C_{72}H_{83}BrN_4O_{12}$

The last base is almost insoluble in ether, whereby it can be separated from the other two, which are readily soluble in that menstruum.

The further action of hydrobromic acid on the above bodies gives rise to the substitution of H for CH_3 in them, the following substances being obtainable by this means:—

Deoxymorphia	$C_{17}H_{19}NO_2$
Bromo-dicodeia-dimorphia .	$C_{70}H_{79}BrN_4O_{12}$
Bromotetramorphia . . .	$C_{68}H_{75}BrN_4O_{12}$

When treated with strong hydrochloric acid at the ordinary temperature, the bromine in the tetra-bases described above is replaced by chlorine. Thus, the following bodies have been analysed (*i. e.* their salts):—

Chlorotetracodeia	$C_{72}H_{83}ClN_4O_{12}$
Chloro-dicodeia-dimorphia .	$C_{70}H_{79}ClN_4O_{12}$
Chlorotetramorphia . . .	$C_{68}H_{75}ClN_4O_{12}$

The physiological action of the above bodies does not appear to be very marked. Dr. Michael Foster finds that the above bodies produce in cats a peculiar excitement of the nervous system and paralysis of inhibitory fibres of the pneumogastric. Deoxycodeia and deoxymorphia salts produce also convulsions of an epileptic character. In case these properties should ever cause the substances to be used in medicine, probably a pill would be the most convenient form of exhibition, as the sparing solubility of their salts in water, and the comparatively large dose requisite, would preclude the use of hypodermic injections.

On treating codeia with hydriodic acid (55 per cent. HI) and a sufficiency of phosphorus, methyl iodide is evolved, and a series of products obtained which much resemble one another in physical characters, being amorphous, brittle or tarry bodies. If the action takes place at 100°, 110°–115°, or at higher temperatures up to 130°, the following three substances appear to be produced:—

I. $C_{68}H_{86}I_2N_4O_{12}, 4HI$. at 100°
II. $C_{68}H_{82}I_2N_4O_{10}, 4HI$. at 110°–115°
III. $C_{68}H_{82}I_2N_4O_6, 4HI$. up to 130°.

On boiling up with water, these bodies part with the elements of hydriodic acid, and either lose or take up those of water. Thus, the following substances have been procured:—

IV. $C_{68}H_{81}IN_4O_{10}, 4HI$. from II.
V. $C_{68}H_{80}N_4O_{10}, 4HI$ . . from both I. and II.
VI. $C_{68}H_{88}N_4O_{10}, 4HI$ . . from III.

A similar reaction also appears to take place by precipitating the solutions of I., II., III. with sodium carbonate; in this way the free bases of the compounds IV. and V. have been obtained from I.

Lastly, on treating with hydriodic acid the compounds IV., V., VI., the elements of hydriodic acid and water are taken up, forming compounds not losing the added water even by long-continued exposure to a temperature of 100°. Thus,—

VI. $C_{68}H_{107}I_3N_4O_{22}, 4HI$. from both IV. and V.
VIII. $C_{68}H_{89}IN_4O_{10}, 4HI$ . . from VI.

While, on treating I. with hydriodic and phosphorus, the following compound (containing the elements of hydriodic acid and water more than III.) was produced:—

IX. $C_{68}H_{103}I_3N_4O_{16}, 4HI$.

The physiological action of the foregoing compounds has not yet been examined particularly, but it does not appear to be marked, no ill-effects having been observed while working with the bodies. Names have not yet been given to these substances, owing to their complexity.

The codeia used in the experiments briefly described above formed part of a large supply exceeding twenty ounces, most liberally presented for the purpose by the eminent manufacturing chemists, Messrs. Macfarlane, of Edinburgh.

The PRESIDENT said that the subject had been very clearly explained by Professor Wright, and he considered it was a paper well worthy of being read at the Conference.

Mr. BRADY said he would like to make one remark about Professor Wright's paper, not that he was going to discuss any point, but as it bore on a little experience he had had, it came with a peculiar force in Edinburgh, which was very much the seat of the morphia manufacture, but it was not so much that as the liberality of the manufacturers of the morphia alkaloids in helping scientific men with materials. Some years ago, when Mr. Deane and himself were making experiments in the morphia alkaloids, in an experimental sense, Messrs. T. and H. Smith and Messrs. Macfarlane assisted them by furnishing materials; and he could not sit there without testifying to their extreme kindness, not in matters of business only, but also to their interest in scientific research.

Professor WRIGHT said that Mr. Brady had called to his mind what he ought to have mentioned before, though it would be seen that it had not been overlooked in his paper. He most sincerely returned thanks to the Messrs. Macfarlane, not only for a supply of codeia, but many other alkaloids. The codeia given by Messrs. Macfarlane weighed upwards of twenty ounces.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE PRESIDENT'S ADDRESS.

(*Concluded from p.* 117.)

Sir William Thomson next spoke of the success of the Kew Magnetic and Meteorological Observatory as affording an example of the great gain to be earned for science by the foundation of physical observatories and laboratories for experimental research, to be conducted by qualified persons, whose duties should be, not teaching, but experimenting. Whether we look to the honour of England, as a nation which ought always to be the foremost in promoting physical science, or to those vast economical advantages which must accrue from such establishments, we cannot but feel that experimental research ought to be made with us an object of national concern, and not left, as hitherto, to the private enterprise of self-sacrificing amateurs, and the necessarily inconsecutive action of our present Governmental Departments and of casual Committees. He referred to a memorial presented by the Council of the Royal Society of Edinburgh to the Royal Commission on Scientific Education and the Advancement of Science, in which occurred the following words:—"On the Continent there exist certain institutions, fitted with instruments, apparatus, chemicals and other appliances, which are meant to be, and which are made available to men of science, to enable them, at a moderate cost, to pursue original researches,"—which he said was corroborated by information he had received from Germany, to the effect that in Prussia "every university, every polytechnical academy, every industrial school (*Realschule* and *Gewerbeschule*), most of the grammar-schools, in a word, nearly all the schools superior in rank to the elementary schools of the common people, are supplied with chemical laboratories and a collection of philosophical instruments and apparatus, access to which is most liberally granted by the directors of those schools, or the teachers of the respective disciplines, to any person qualified, for *scientific experiments*. In consequence, though there exist no particular institutions like those mentioned in the memorial, there will scarcely be found a town exceeding in number 5000 inhabitants but offers the possibility of *scientific explorations* at no other cost than reimbursement of the expense for the materials wasted in the experiments."

The physical laboratories which have grown up in the Universities of Glasgow and Edinburgh, and in Owens College, Manchester, show the want felt of Colleges of Research; but they go but infinitesimally towards supplying it, being absolutely destitute of means, material or personal, for advancing science except at the expense of volunteers, or securing that volunteers shall be found to continue even such little work as at present is carried on.

The whole of Andrews' splendid work in Queen's College, Belfast, has been done under great difficulties and disadvantages and at great personal sacrifices, and up to the present time there is not a student's physical laboratory in any one of the Queen's Colleges in Ireland—a want which surely ought not to remain unsupplied. Each of these institutions (the four Scotch Universities, the three Queen's Colleges, and Owens College, Manchester) requires two professors of natural philosophy—one who shall be responsible for the teaching, the other for the advancement of science by experiment. The

University of Oxford has already established a physical laboratory. The munificence of its Chancellor is about to supply the University of Cambridge with a splendid laboratory, to be constructed under the eye of Professor Clerk Maxwell.

Besides abstracts of papers read and discussions held before the sections, the annual Reports of the British Association contain a large mass of valuable matter of another class. The speaker then alluded to the early practice of the Association, a practice that might well be further developed, to call occasionally for a special report on some particular branch of science from a man eminently qualified for the task. Some of the reports received in compliance with these invitations have done good service in their time, and remain permanently useful as landmarks in the history of science. The two kinds of efficiency realized in this department of the Association's work may be illustrated by referring to Cayley's Report on Abstract Dynamics and Sabine's Report on Terrestrial Magnetism (1838).

He then referred to different investigators of the science of terrestrial magnetism, and said that in Wales, Sir Edward and Lady Sabine are at work on the magnetic chart of the world. If two years of life and health are granted to them, science will be provided with a key which must powerfully conduce to the ultimate opening up of one of the most refractory enigmas of cosmical physics, the cause of terrestrial magnetism.

In giving a sketch of scientific investigation performed during the past year he would simply choose some of those which had struck him as most notable.

Accurate and minute measurement seems to the non-scientific imagination a less lofty and dignified work than looking for something new. But nearly all the grandest discoveries of science have been but the rewards of accurate measurement and patient and long-continued labour in the minute sifting of numerical results. The popular idea of Newton's grandest discovery is that the theory of gravitation flashed into his mind, and so the discovery was made. It was by long train of mathematical calculation, founded on results accumulated through prodigious toil of practical astronomers, that Newton first demonstrated the forces urging the planets towards the sun, determined the magnitudes of those forces, and discovered that a force following the same law of variation with distance urges the moon towards the earth. *Then* first, we may suppose, came to him the idea of the universality of gravitation; but when he attempted to compare the magnitude of the force on the moon with the magnitude of the force of gravitation of a heavy body of equal mass at the earth's surface, he did not find the agreement which the law he was discovering required. Not for years after would he publish his discovery as made. It is recounted that, being present at a meeting of the Royal Society, he heard a paper read, describing geodesic measurement by Picard which led to a serious correction of the previously accepted estimate of the earth's radius. This was what Newton required. He went home with the result and commenced his calculations, but felt so much agitated that he handed over the arithmetical work to a friend: then (and not when, sitting in a garden, he saw an apple fall) did he ascertain that gravitation keeps the moon in her orbit.

Other instances of important results from minute and accurate measurement were mentioned, and an opinion expressed that great service has been done to science by the British Association in promoting accurate measurement in various subjects.

The greatest achievement yet made in molecular theory of the properties of matter is the Kinetic theory of Gases, shadowed forth by Lucretius, definitely stated by Daniel Bernoulli, largely developed by Herapath, made a reality by Joule, and worked out to its present advanced state by Clausius and Maxwell. Joule, from his dynamical equivalent of heat, and his experiments upon the heat produced by the condensation of gas, was able to estimate the average velocity of the ultimate molecules or atoms composing it. His estimate for hydrogen was 6225 feet per second at temperature 60° Fahr., and 6055 feet per second at the freezing-point. Clausius took fully into account the impacts of molecules on one another, and the kinetic energy of *relative* motions of the matter constituting an individual atom. He investigated the relation between their diameters, the number in a given space, and the mean length of path from impact to impact, and so gave the foundation for estimates of the absolute dimensions of atoms, to which I shall refer later. He explained the slowness of gaseous diffusion by the mutual impacts of the atoms, and laid a secure foundation for a complete theory of the diffusion of fluids, previously a most refractory enigma. The deeply penetrating genius of Maxwell brought in viscosity and thermal conductivity, and thus completed the dynamical explanation of all the known properties of gases, except their electric resistance and brittleness to electric force.

No such comprehensive molecular theory had ever been even imagined before the nineteenth century. Definite and complete in its area as it is, it is but a well-drawn part of a great chart, in which all physical science will be represented with every property of matter shown in dynamical relation to the whole. The prospect we now have of an early completion of this chart is based on the assumption of atoms. But there can be no permanent satisfaction to the mind in explaining heat, light, elasticity, diffusion, electricity and magnetism, in gases, liquids, and solids, and describing precisely the relations of these different states of matter to one another by statistics of great numbers of atoms, when the properties of the atom itself are simply assumed. When the theory, of which we have the first instalment in Clausius and Maxwell's work, is complete, we are but brought face to face with a superlatively grand question, what is the inner mechanism of the atom?

In the answer to this question we must find the explanation not only of the atomic elasticity, by which the atom is a chronometric vibrator according to Stokes's discovery, but of chemical affinity and of the differences of quality of different chemical elements, at present a mere mystery in science. Helmholtz's exquisite theory of vortex-motion in an incompressible frictionless liquid has been suggested as a finger-post, pointing a way which may possibly lead to a full understanding of the properties of atoms, carrying out the grand conception of Lucretius, who "admits no subtle ethers, no variety of elements with fiery, or watery, or light, or heavy principles; nor supposes light to be one thing, fire another, electricity a fluid, magnetism a vital principle, but treats all phenomena as mere properties or accidents of simple matter." This statement I take from an admirable paper on the atomic theory of Lucretius, which appeared in the *North British Review* for March, 1868, containing a most instructive summary of ancient and modern doctrine regarding atoms. Allow me to read from that article one other short passage finely describing the present aspect of atomic theory:—"The existence of the chemical atom, already quite a complex little world, seems very probable: and the description of the Lucretian atom is wonderfully applicable to it. We are not wholly without hope that the real weight of each atom may some day be known—not merely the relative weight of the several atoms, but the number in a given volume of any material; that the form and motion of the parts of each atom and the distances by which they are separated may be calculated; that the motions by which they produce heat, electricity, and light may be illustrated by exact geometrical diagrams; and that the fundamental properties of the intermediate and possibly constituent medium may be arrived at. Then the motion of planets and music of the spheres will be neglected for a while in admiration of the maze in which the tiny atoms run."

Even before this was written some of the anticipated results had been partially attained. Loschmidt in Vienna had shown, and not much later Stoney independently in England showed, how to deduce from Clausius and Maxwell's kinetic theory of gases a superior limit to the number of atoms in a given measurable space. I was unfortunately quite unaware of what Loschmidt and Stoney had done when I made a similar estimate on the same foundation, and communicated it to *Nature* in an article on "The Size of Atoms." But questions of personal priority, however interesting they may be to the persons concerned, sink into insignificance in the prospect of any gain of deeper insight into the secrets of nature. The triple coincidence of independent reasoning in this case is valuable as confirmation of a conclusion violently contravening ideas and opinions which had been almost universally held regarding the dimensions of the molecular structure of matter. Chemists and other naturalists had been in the habit of evading questions as to the hardness or indivisibility of atoms by virtually assuming them to be infinitely small and infinitely numerous. We must now no longer look upon the atom, with Boscovich, as a mystic point endowed with inertia and the attribute of attracting or repelling other such centres with forces depending upon the intervening distances (a supposition only tolerated with the tacit assumption that the inertia and attraction of each atom is infinitely small and the number of atoms infinitely great), nor can we agree with those who have attributed to the atom occupation of space with infinite hardness and strength (incredible in any finite body); but we must realize it as a piece of matter of measurable dimensions, with shape, motion, and laws of action, intelligible subjects of scientific investigation.

The prismatic analysis of light discovered by Newton was estimated by himself as being "the oddest, if not the most considerable, detection which hath hitherto been made in the operations of nature."

Had he not been deflected from the subject, he could not have failed to obtain a pure spectrum; but this, with the inevitably consequent discovery of the dark lines, was reserved for the nineteenth century. Our fundamental knowledge of the dark lines is due solely to Fraunhofer. Wollaston saw them, but did not discover them. Brewster laboured long and well to perfect the prismatic analysis of sunlight; and his observations on the dark bands produced by the absorption of interposed gases and vapours laid important foundations for the grand superstructure which he scarcely lived to see. Piazzi Smyth, by spectroscopic observation performed on the Peak of Teneriffe, added greatly to our knowledge of the dark lines produced in the solar spectrum by the absorption of our own atmosphere. The prism became an instrument for chemical qualitative analysis in the hands of Fox Talbot and Herschel, who first showed how, through it, the old "blowpipe test," or generally the estimation of substances from the colours which they give to flames, can be prosecuted with an accuracy and a discriminating power not to be attained when the colour is judged by the unaided eye. But the application of this test to solar and stellar chemistry had never, I believe, been suggested, either directly or indirectly, by any other naturalist, when Stokes taught it to me in Cambridge at some time prior to the summer of 1852. The observational and experimental foundations on which he built were:—

(1) The discovery by Fraunhofer of a coincidence between his double dark line D of the solar spectrum and a double bright line which he observed in the spectra of ordinary artificial flames.

(2) A very rigorous experimental test of this coincidence by Professor W. H. Miller, which showed it to be accurate to an astonishing degree of minuteness.

(3) The fact that the yellow light given out when salt is thrown on burning spirit consists almost solely of the two nearly identical qualities which constitute that double bright line.

(4) Observations made by Stokes himself, which showed the bright line D to be absent in a candle-flame when the wick was snuffed clean, so as not to project into the luminous envelope, and from an alcohol flame when the spirit was burned in a watch-glass. And

(5) Foucault's admirable discovery (L'Institut, Feb. 7, 1849) that the voltaic arc between charcoal points is "a medium which emits the rays D on its own account, and at the same time absorbs them when they come from another quarter."

The conclusions, theoretical and practical, which Stokes taught me, and which I gave regularly afterwards in my public lectures in the University of Glasgow, were:—

(1) That the double line D, whether bright or dark, is due to vapour of sodium.

(2) That the ultimate atom of sodium is susceptible of regular elastic vibrations, like those of a tuning-fork or of stringed musical instruments; that like an instrument with two strings tuned to approximate unison, or an approximately circular elastic disk, it has two fundamental notes or vibrations of approximately equal pitch; and that the periods of these vibrations are precisely the periods of the two slightly different yellow lights constituting the double bright line D.

(3) That when vapour of sodium is at a high enough temperature to become itself a source of light, each atom executes these two fundamental vibrations simultaneously; and that, therefore, the light proceeding from it is of the two qualities constituting the double bright line D.

(4) That when vapour of sodium is present in space across which light from another source is propagated, its atoms, according to a well-known general principle of dynamics, are set to vibrate in either or both of those fundamental modes, if some of the incident light is of one or other of their periods, or some of one and some of the other; so that the energy of the waves of those particular qualities of light is converted into thermal vibrations of the medium and dispersed in all directions, while light of all other qualities, even though very nearly agreeing with them, is transmitted with comparatively no loss.

(5) That Fraunhofer's double dark line D of solar and stellar spectra is due to the presence of vapour of sodium in atmospheres surrounding the sun and those stars in whose spectra it had been observed.

(6) That other vapours than sodium are to be found in the atmospheres of the sun and stars by searching for substances producing in the spectra of artificial flames bright lines coinciding with other dark lines of the solar and stellar spectra than the Fraunhofer line D.

The last of these propositions I felt to be confirmed (it was perhaps partly suggested) by a striking and beautiful experiment admirably adapted for lecture illustrations, due to Foucault, which had been shown to me by M. Duboscque Soleil, and the Abbé Moigno, in Paris in the month of October, 1850. A prism and lenses were arranged to throw upon a screen an approximately pure spectrum of a vertical electric arc between charcoal poles of a powerful battery, the lower one of which was hollowed like a cup. When pieces of copper and pieces of zinc were separately thrown into the cup, the spectrum exhibited, in perfectly definite positions, magnificent well-marked bands of different colours characteristic of the two metals. When a piece of brass, compounded of copper and zinc, was put into the cup, the spectrum showed all the bands, each precisely in the place in which it had been seen when one metal or the other had been used separately.

To Kirchhoff belongs, I believe, solely the great credit of having first actually sought for and found other metals than sodium in the sun by the method of spectrum analysis. His publication of October, 1859, inaugurated the practice of solar and stellar chemistry, and gave spectrum analysis an impulse to which, in a great measure, is due its splendidly successful cultivation by the labours of many able investigators within the last ten years.

To prodigious and wearing toil of Kirchhoff himself, and of Angström, we owe large-scale maps of the solar spectrum, incomparably superior, in minuteness and accuracy of delineation, to anything ever attempted previously. These maps now constitute the standards of reference for all workers in the field. Plücker and Hittorf opened ground in advancing the physics of spectrum analysis and made the important discovery of changes in the spectra of ignited gases, produced by changes in the physical condition of the gas. The scientific value of the meetings of the British Association is well illustrated by the fact that it was through conversation with Plücker, at the Newcastle meeting, that Lockyer was first led into the investigation of the effects of varied pressure on the quality of the light emitted by glowing gas, which he and Frankland have prosecuted with such admirable success. Scientific wealth tends to accumulation according to the law of compound interest. Every addition to knowledge of properties of matter supplies the naturalist with new instrumental means for discovering and interpreting phenomena of nature, which in their turn afford foundations for fresh generalizations, bringing gains of permanent value into the great storehouse of philosophy. Thus Frankland, led, from observing the want of brightness of a candle burning in a tent on the summit of Mont Blanc, to scrutinize Davy's theory of flame, discovered that brightness, without incandescent solid particles, is given to a purely gaseous flame by augmented pressure, and that a dense ignited gas gives a spectrum comparable with that of the light from an incandescent solid or liquid. Lockyer joined him, and the two found that every incandescent substance gives a continuous spectrum; that an incandescent gas under varied pressure gives bright bars across the continuous spectrum, some of which, from the sharp, hard and fast lines observed where the gas is in a state of extreme attenuation, broaden out on each side into nebulous bands as the density is increased, and are ultimately lost in the continuous spectrum when the condensation is pushed on till the gas becomes a fluid no longer to be called gaseous. More recently they have examined the influence of temperature, and have obtained results which seem to show that a highly attenuated gas, which at a high temperature gives several bright lines, gives a smaller and smaller number of lines, of sufficient brightness to be visible, when the temperature is lowered, the density being kept unchanged.

Stokes's dynamical theory supplies the key to the philosophy of Frankland and Lockyer's discovery. Any atom of gas when struck and left to itself vibrates with perfect purity its fundamental note or notes. In a highly attenuated gas each atom is very rarely in collision with other atoms, and therefore is nearly at all times in a state of true vibration. Hence the spectrum of a highly attenuated gas consists of one or more perfectly sharp bright lines, with a scarcely perceptible continuous gradation of prismatic colour. In denser gas each atom is frequently in collision, but still is for much more time free, in intervals between collisions, than engaged in collision; so that not only is the atom itself thrown sensibly out of tune during a sensible proportion of its whole time, but the confused jangle of vibrations in every variety of period during the actual collision becomes more considerable in its influence. Hence bright lines in the spectrum broaden out somewhat, and the continuous spectrum becomes less faint. In still denser gas each atom may be almost as much time in collision as free, and the spectrum then consists of broad nebulous bands crossing a continuous spectrum of considerable brightness. When the medium is so dense that each atom is always in collision—that is to say, never free from influence of its neighbours—the spectrum will generally be continuous, and may present little or no appearance of bands, or even of maxima of brightness. In this condition the fluid can be no longer regarded as a gas, and we must judge of its relation to the vaporous or liquid states according to the critical conditions discovered by Andrews.

While these great investigations of properties of matter were going on, naturalists were not idle with the newly-recognized power of the spectroscope at their service. Chemists soon followed the example of Bunsen in discovering new metals in terrestrial matter by the old blow-pipe and prism test of Fox Talbot and Herschel. Biologists applied spectrum analysis to animal and vegetable chemistry, and to sanitary investigations. But it is in astronomy that spectroscopic research has been carried on with the greatest activity, and been most richly rewarded with results. The chemist and the astronomer have joined their forces. An astronomical observatory has now appended to it a stock of reagents such as hitherto was only to be found in the chemical laboratory. A devoted corps of volunteers of all nations, whose motto might well be *ubique*, have directed their artillery to every region of the universe. The sun, the spots on his surface, the corona and the red and yellow prominences seen round him during total eclipses, the moon, the planets, comets, auroras, nebulæ, white stars, yellow stars, red stars, variable and temporary stars, each tested by the prism was compelled to show its distinguishing prismatic colours. Rarely before in the history of science has enthusiastic perseverance, directed by penetrative genius, produced within ten years so brilliant a succession of discoveries. It is not merely the *chemistry* of sun and stars, as first suggested, that is subjected to analysis by the spectroscope. Their whole laws of being are now subjects of direct investigation; and already we have glimpses of their evolutional history through the stupendous power of this most subtle and delicate test. We had only solar and stellar chemistry; we now have solar and stellar physiology.

It is an old idea that the colour of a star may be influenced by its motion relatively to the eye of the spectator, so as to be tinged with red if it moves from the earth, or blue if it moves towards the earth. William Allen Miller, Huggins and Maxwell showed how, by aid of the spectroscope, this idea may be made the foundation of a method of measuring the relative velocity with which a star approaches to or recedes from the earth. The principle is, first to identify, if possible, one or more of the lines in the spectrum of the star, with a line or lines in the spectrum of sodium, or some other terrestrial substance, and then (by observing the star and the artificial light simultaneously by the same spectroscope) to find the difference, if any, between their refrangibilities. From this difference of refrangibility the ratio of the periods of the two lights is calculated, according to data determined by Fraunhofer from comparisons between the positions of the dark lines in the prismatic spectrum and in his own "interference spectrum" (produced by substituting for the prism a fine grating). A first comparatively rough application of the test by Miller and Huggins to a large number of the principal stars of our skies, proved that not one of them had so great a velocity as 315 kilometres per second to or from the earth, which is a *most momentous result in respect to cosmical dynamics.* Afterwards Huggins made special observations of the velocity test, and succeeded in making the measurement in one case, that of Sirius, which he then found to be receding from the earth at the rate of 66 kilometres per second. This, corrected for the velocity of the earth at the time of the observation, gave a velocity of Sirius, relatively to the sun, amounting to 47 kilometres per second.

During six or eight precious minutes of time, spectroscopes have been applied to the solar atmosphere and to the corona seen round the dark disk of the moon eclipsing the sun. Some of the wonderful results of such observations, made in India on the occasion of the eclipse of August, 1868, were described by Professor Stokes in a previous address. Valuable results have, through the liberal assistance given by the British and American Governments, been obtained also from the total eclipse of last December, notwithstanding a generally unfavourable condition of weather. It seems to have been proved that at least some sensible part of the light of the "corona" is a terrestrial atmospheric halo or dispersive reflection of the light of the glowing hydrogen and "helium"* round the sun.

The speaker, referring to former hypotheses concerning the solar system, and specially to Mayer's theory that the sun's heat is supplied dynamically from year to year by the influx of meteors, said that now spectrum analysis gives proof finally conclusive against it.

Most important steps have been recently made towards the discovery of the nature of comets; establishing with nothing short of certainty the truth of a hypothesis which had long appeared to me probable,—that they consist of groups of meteoric stones; accounting satisfactorily for the light of the nucleus; and giving a simple and rational explanation of phenomena presented by the tails of comets which had been regarded by the greatest astronomers as almost preternaturally marvellous. The investigations of Professor Newton, of Yale College, United States, followed and completed by those of Adams, proved that Temple's Comet I., 1866, consists of an elliptic train of minute planets, of which a few thousands or millions fall to the earth annually about the 14th of November, when we cross their track. We have probably not yet passed through the very nucleus or densest part; but thirteen times, in Octobers and Novembers, from October 13, A.D. 902, to November 14, 1866, inclusive (this last time having been correctly predicted by Professor Newton), we have passed through a part of the belt greatly denser than the average. The densest part of the train, when near enough to us, is visible as the head of the comet.

The essence of science, as is well illustrated by astronomy and cosmical physics, consists in inferring antecedent conditions, and anticipating future evolutions, from phenomena which have actually come under observation. In biology the difficulties of successfully acting up to this ideal are prodigious. The earnest naturalists of the present day are, however, not appalled or paralysed by them, and are struggling boldly and laboriously to pass out of the mere "natural history" stage of their study, and bring zoology within the range of natural philosophy. A very ancient speculation, still clung to by many naturalists (so much so that I have a choice of modern terms to quote in expressing it), supposes that, under meteorological conditions very different from the present, dead matter may have run together or crystallized or fermented into "germs of life," or "organic cells," or "protoplasm." But science brings a vast mass of inductive evidence against this hypothesis of spontaneous generation, as you have heard from my predecessor in the presidential chair. Careful enough scrutiny has, in every case up to the present day, discovered life as antecedent to life. Dead matter cannot become living without coming under the influence of matter previously alive. This seems to me as sure a teaching of science as the law of gravitation. I utterly repudiate, as opposed to all philosophical uniformitarianism, the assumption of "different meteorological conditions,"—that is to say, somewhat different vicissitudes of temperature, pressure, moisture, gaseous atmosphere,—to produce or to permit that to take place by force or motion of dead matter alone, which is a direct contravention of what seems to us biological law. I am prepared for the answer, "our code of biological law is an expression of our ignorance as well as of our knowledge." And I say yes: search for spontaneous generation out of inorganic materials; let any one not satisfied with the purely negative testimony of which we have now so much against it, throw himself into the inquiry. Such investigations as those of Pasteur, Pouchet and Bastian are among the most interesting and momentous in the whole range of natural history; and their results, whether positive or negative, must richly reward the most careful and laborious experimenting. I confess to being deeply impressed by the evidence put before us by Professor Huxley, and I am ready to adopt, as an article of scientific faith, true through all space and through all time, that life proceeds from life, and from nothing but life.

How, then, did life originate on the earth? Tracing the physical history of the earth backwards, on strict dynamical principles, we are brought to a red-hot melted globe on which no life could exist. Hence, when the earth was first fit for life, there was no living thing on it. There were rocks solid and disintegrated, water, air all round, warmed and illuminated by a brilliant sun, ready to become a garden. Did grass and trees and flowers spring into existence, in all the fulness of ripe beauty, by a fiat of Creative Power? or did vegetation, growing up from seed sown, spread and multiply over the whole earth? Science is bound, by the everlasting law of honour, to face fearlessly every problem which can fairly be presented to it. If a probable solution, consistent with the ordinary course of nature, can be found, we must not invoke an abnormal act of Creative Power. When a lava-stream flows down the sides of Vesuvius or Etna, it quickly cools and becomes solid; and after a few weeks or years it teems with vegetable and animal life, which for it originated by the transport of seed and ova, and by the migration of individual living creatures. When a volcanic island springs up from the sea, and after a few years is found clothed with vegetation, we do not hesitate to assume that seed has been wafted to it through the air, or floated to it on rafts. Is it not possible, and, if possible, is it not probable, that the beginning of vegetable life on the earth is to be similarly explained? Every year thousands, probably millions, of fragments of solid matter fall upon the earth: whence came these fragments? What is the previous history of any one of them? Was it created in the beginning of time an amorphous mass? This idea is so unacceptable that, tacitly or explicitly, all men discard it. It is often assumed that all, and it is certain that some, meteoric stones are fragments which had been broken off from greater masses and launched free into space. It is as sure that collisions must occur between great masses moving through space as it is that ships, steered without intelligence directed to prevent collision, could not cross and recross the Atlantic for thousands of years with immunity from collisions. When two great masses come into collision in space it is certain that a large part of each is melted; but it seems also quite certain that in many cases a large quantity of *débris* must be shot forth in all directions, much of which may have experienced no greater violence than individual pieces of rock experience in a land-slip or in blasting by gunpowder. Should the time when this earth comes into collision with another body, comparable in dimensions to itself, be when it is still clothed as at present with vegetation, many great and small fragments carrying seed and living plants and animals would undoubtedly be scattered through space. Hence and because we all confidently believe that there are at present, and have been from time immemorial, many worlds of life besides our own, we must regard it as probable in the highest degree that there are countless seed-bearing meteoric stones moving about through space. If at the present instant no life existed upon this earth, one such stone falling upon it might, by what we blindly call *natural* causes, lead to its becoming covered with vegetation. I am fully conscious

* Frankland and Lockyer find the yellow prominences to give a very decided bright line not far from D, but hitherto not identified with any terrestrial flame. It seems to indicate a new substance, which they propose to call helium.

of the many scientific objections which may be urged against this hypothesis, but I believe them to be all answerable. I have already taxed your patience too severely to allow me to think of discussing any of them on the present occasion. The hypothesis that life originated on this earth through moss-grown fragments from the ruins of another world may seem wild and visionary; all I maintain is that it is not unscientific.

From the earth stocked with such vegetation as it could receive meteorically, to the earth teeming with all the endless variety of plants and animals which now inhabit it, the step is prodigious; yet, according to the doctrine of continuity, most ably laid before the Association by a predecessor in this chair (Mr. Grove), all creatures now living on earth have proceeded by orderly evolution from some such origin. Darwin concludes his great work on 'The Origin of Species' with the following words:—"It is interesting to contemplate an entangled bank clothed with many plants of many kinds, with birds singing on the bushes, with various insects flitting about, and with worms crawling through the damp earth, and to reflect that these elaborately constructed forms, so different from each other, and dependent on each other in so complex a manner, have all been produced by laws acting around us." . . . . "There is grandeur in this view of life with its several powers, having been originally breathed by the Creator into a few forms or into one; and that, whilst this planet has gone cycling on according to the fixed law of gravity, from so simple a beginning endless forms, most beautiful and most wonderful, have been and are being evolved." With the feeling expressed in these two sentences I most cordially sympathize. I have omitted two sentences which come between them, describing briefly the hypothesis of "the origin of species by natural selection," because I have always felt that this hypothesis does not contain the true theory of evolution, if evolution there has been, in biology. Sir John Herschel, in expressing a favourable judgment on the hypothesis of zoological evolution, with, however, some reservation in respect to the origin of man, objected to the doctrine of natural selection, that it was too like the Laputan method of making books, and that it did not sufficiently take into account a continually guiding and controlling intelligence. This seems to me a most valuable and instructive criticism. I feel profoundly convinced that the argument of design has been greatly too much lost sight of in recent zoological speculations. Reaction against the frivolities of teleology, such as are to be found, not rarely, in the notes of the learned commentators on Paley's 'Natural Theology,' has, I believe, had a temporary effect in turning attention from the solid and irrefragable argument so well put forward in that excellent old book. But overpoweringly strong proofs of intelligent and benevolent design lie all round us, and if ever perplexities, whether metaphysical or scientific, turn us away from them for a time, they come back upon us with irresistible force, showing to us through nature the influence of a free will, and teaching us that all living beings depend on one ever-acting Creator and Ruler.

Parliamentary and Law Proceedings.

Alleged Death through taking "Vegetable Pills."

An inquest was held at Bridlington Quay, on the 18th ult., to inquire into the cause of death of Miss Anne Dowsland, who was found dead at her residence on the previous Sunday. From the evidence, it appeared that the deceased had complained to her neighbours of bad health, and suffered from asthma and shortness of breath. On the Saturday week previous to her death she had been called upon by Mr. Robinson, of Hull, from whom she had previously received a circular, and persuaded by him to purchase a box of his pills, which he said would do her more good than anything. She took three pills in water the first night, two on the Monday night, and two on Tuesday morning, after which she was very much purged up to the time of her death.

Mr. Robinson, having been cautioned, said that he was a "medical herbalist," residing in Grimsby Lane, Market Place, Hull. He called on the deceased, who complained of a pressure and gathering of wind at the chest and stomach and costiveness, and sold her a box of his "vegetable pills." He saw she was very low and weak, and advised her to take rice and boiled milk, and a tablespoonful of raw Jamaica rum in the middle of the forenoon; he also gave directions as to the time and way the pills should be taken. The ingredients of the pills were jalap, aloes, ginger, half a drachm of cayenne or capsicum in a 2 lb. mass, with carbonate of soda and simple syrup. In answer to a juror, witness said he had taken six similar pills on Saturday night previous and six on the following morning without sustaining any injurious consequences. The diet he prescribed was intended as a corrective to any purgative action. He did not prescribe the pills for every class of ailment.

The medical gentlemen who had conducted a *post-mortem* examination gave evidence as to the state of the body. They were of opinion that the diseased state of the lungs must eventually have proved fatal, but that drastic purgatives would have a depressing effect upon a person suffering from extreme exhaustion; and that under the circumstances the taking of these pills would have had a tendency to accelerate death.

The jury returned a verdict of "Death from natural causes, accelerated by incautiously taking purgative medicine."

We are informed that after the conclusion of the inquest Mr. Robinson was arrested by the police, on a warrant charging him with manslaughter. Some of the pills were forwarded to an analyst for examination.

Poisoning of a Family by Prussic Acid.

A case of poisoning occurred at Glasgow, on Thursday, August 5th, in which three children and their father died from the effects of prussic acid. It appears that the father, Mr. Nimmo, in a fit of mental aberration, mixed some prussic acid with wine, which he gave to four of his children, aged respectively 7 years, 5 years, 3 years, and 20 months. A servant, attracted by the moaning of the youngest child, went into the room, and saw the father bending over the bed. He made an excuse, which satisfied her for the time, but on going to the other children she saw there was something wrong, and gave the alarm. Assistance was immediately obtained, when the three youngest children and Mr. Nimmo were found to be dead. The eldest child had been offered some wine by his father, but he only tasted it, and, disliking it, would not take any more. The glass was afterwards found to contain a mixture of wine and prussic acid. This child has since recovered.

Mr. Nimmo is said to have obtained the prussic acid from a firm in Glasgow which was in the habit of supplying him with goods necessary for his business, stating that he wanted it for use in a chemical process. A member of the firm took the precaution to go to Kilsyth, where the deceased had just erected a millboard factory, and deliver the prussic acid to him in person. At the same time, he warned Mr. Nimmo that, being required, as he alleged, for experimental purposes, it was of the strongest manufacture, and extreme caution would be required in its use.

Poisoning by an Overdose of Morphia.

An inquest has been held at Sidmouth to inquire into the death of Mr. William Ellis Wall, a private gentleman, residing at Salcombe Regis.

Mrs. Wall, the widow, deposed to the deceased having, about two o'clock on Saturday afternoon, written out a prescription, and sent it by a servant to Mr. Webber, chemist, to be made up. He then went to bed, and, not having received the draught, he sent the girl again to Mr. Webber's at nine o'clock to fetch it. The girl brought back a bottle (which was produced), and, following the directions on the bottle and her husband's previous directions, she gave him one-half of the mixture immediately. Directly afterwards, the housemaid came to say that the wrong medicine had been sent. In about five minutes her husband began to breathe unnaturally. She sent for Dr. M'Kenzie, who, however, had nearly reached the house with Dr. Atkins, and met the servant in the drive. Mrs. Wall said that her husband was in the habit of taking opium, and of prescribing for himself. He had taken but little substantial food during that or the previous day, but on Saturday had drunk three large bottles of champagne.

Jane Shepherd, the servant already mentioned, said she was sent with the prescription by her master in the afternoon, and again in the evening, when Mr. Robert Webber prepared the mixture in her presence. Shortly after, a messenger brought a bottle to the house, saying that Mr. Webber had sent the wrong draught, and requiring to have the previous mixture returned.

Walter Pinn, an apprentice, said he was directed by Mr. Robert Webber, about twenty-five minutes to ten, to go as quickly as possible to Mr. Wall's with a bottle, and to say that the wrong medicine had been sent, which he was to bring back immediately. On his return, about ten minutes after, he was sent to ask Dr. M'Kenzie to come to Mr. Webber's.

Dr. M'Kenzie stated that he was sent for at about twenty minutes to ten to go to Mr. Webber's, and that on his arrival Mr. Webber told him that he had made a mistake, and that instead of putting in half a drachm of solution (equal to half a grain) of muriate of morphia, he had put in a scruple (equal to 20 grains) of the drug, half of which quantity would kill any habitual morphia taker. Dr. Atkins was in the shop, and they both hastened to Mr. Wall's, taking materials for a powerful emetic. Dr. M'Kenzie described Mr. Wall's symptoms when he first saw him, and the remedies which were applied. Mr. Wall died about a quarter-past three on Sunday morning. He had made a *post-mortem* examination, and had no doubt that death was caused by an overdose of morphia. Mr. R. Webber was in the room the whole of the time, rendering any assistance that was in his power.

Confirmatory evidence having been given by Drs. Hodges and Atkins, the coroner, in summing up, said that the evidence clearly established that death was caused by an overdose of morphia prepared by Mr. R. Webber; and pointed out that if a man undertook an office requiring care and skill, and by his want of skill or negligence caused the death of another, the law held him guilty of manslaughter; and it would be for the jury to consider whether the prescription had been prepared with the skill and care the law required, and find their verdict accordingly.

The jury, in about a quarter of an hour, found a verdict of "Death by misadventure," requesting the coroner to admonish Mr. Webber to be more careful for the future, which he did.—*Tiverton Gazette and East Devon Herald.*

[*** We are informed that Mr. Charles Webber, the principal, was absent from home through indisposition, and that Mr. Robert Webber, a younger brother, was left in charge of the business.—Ed. Pharm. Journ.]

Poisoning by Carbolic Acid.

An inquest was held on Tuesday, at Salford, concerning the death of Isabella Storks, aged one year and ten months. The mother of the deceased said her husband was a private soldier, now with his regiment. She resided in St. John's Wood. Some carbolic acid was received from the nuisance department for the purpose of disinfecting the house where a case of smallpox had recently occurred. Part of it had been used and the remainder was left in a bottle, and placed amongst other similar bottles in a cupboard. The child got to the cupboard and drank some of the acid in the bottle. She became very ill, and was shortly afterwards removed to the Infirmary where she died.

Dr. Syson, Medical Officer of Health for Salford, was present at the inquiry, and said the carbolic acid in the bottle produced was in a crude state. He had given strict instructions that it should not be left in that state at any house, but that the nuisance officers should take it to the houses and dilute it there before it was handed to the occupants for use. The officer who took the acid to the house in question was at present away on leave.

The jury returned a verdict of "Accidental death," and, at their request, Dr. Syson promised to make further inquiries into the matter, and report to the committee if he considered the conduct of the nuisance officer rendered such a step necessary.—*Manchester Courier.*

Poisoning by an Overdose of Laudanum.

An inquest was held Friday, August 4, concerning the death of a child two years old, daughter of George Whittaker, residing in Pendleton. It appeared that a nurse that had been in attendance upon the child, who was suffering from a severe cough, recommended the mother to give it a dose of paregoric and aniseed. By a mistake laudanum and aniseed was purchased from the chemist's, and some of the mixture was administered to the child, who died in consequence. After several witnesses had been examined, the jury returned a verdict of "Accidental death."—*Manchester Courier.*

Cambridge Poisoning Case.

There was a further remand of the prisoner in this case, to enable Professor Liveing to confer with Dr. Letheby respecting the different results arrived at by the two analysts.

The Act to Prevent the Use of Stills by Unlicensed Persons.

Sir,—A good deal has been lately said *pro* and *con.* as to whether the word "may" in a certain clause of the Pharmacy Act, referring to future regulations for keeping, dispensing, etc., of poisons," bears the same meaning as "shall" or "must." I am one of those who are decidedly of opinion that they bear, and were intended to bear, this obligatory meaning.

There is, however, another Act of Parliament, in which chemists are interested, where the same word occurs, and as it appears to me, bears the same meaning as in the former case.

In the "Act to Prevent the Use of Stills by Unlicensed Persons," there is contained this clause, "Provided always, that the Commissioners of Excise 'may' permit the keeping and using of any still or stills for experiments in chemistry under such regulations as they think fit; provided also, that the Commissioners of Excise 'may' permit the keeping and using of any still or stills by persons carrying on trade or otherwise, for the manufacture of articles other than spirits or spirit mixtures upon every person who has a still giving notice thereof to the nearest officer of Excise, and conforming to such regulations as the Commissioners of Excise think fit to direct before beginning to use any still as last aforesaid."

Now, if these exceptional provisions mean anything, they mean that pharmaceutists (who carry on trade), as well as scientific chemists, professors and others (who do not carry on trade), are entitled to exemption from the licence duty of 10*s.* upon every retort and still kept and used for purposes of scientific investigation, or in making the preparations of the P. B. other than spirits and spirit mixtures.

The Commissioners and their officials, however, in direct opposition to the intentions of the Legislature, insist upon the licence duty being paid in all cases where the still or retort is used for purposes of trade,—this being the purport of the reply I received, first, from the officer of the district, and afterwards from the Board of Inland Revenue, on direct application being made for permission to keep a 1 gall. still exclusively for the preparation of distilled water. Of course this is an article of primary necessity to all engaged in the preparation and dispensing of medicines, and no obstacle should be thrown in the way of any one so engaged, who wishes strictly to comply with the directions of the Pharmacopœia.

I think the matter is one of sufficient importance to be brought under the notice of the Council, for the purpose of ascertaining the meaning of "may permit;" whether it means, "will not permit" under any circumstances, or "shall permit" in such cases as ours.—Aqua Destillata.

Preparation for Passing the Examinations.

Sir,—I see, with much regret, that thirty-five out of sixty candidates failed to pass the Minor examination on the 12th, 14th, and 19th of July. Surely it is time that our young men should know better how to prepare for this ordeal, and that their masters should urge upon them the need for *real and fundamental preparation*, rather than the cramming which I have no doubt the examiners easily detect.

Some years since Mr. Ince advised the study of a language, in order to prepare the mind for the sciences a chemist must acquire, but, having tried the plan, I would rather advise, as I do to my own pupils, the study of practical and systematic botany at as early a period as may be possible; this, with a master's occasional supervision, leads to so much instruction about the drugs belonging to the same Natural Orders as the plants under notice, that botany becomes a pleasant and easy commencement of materia medica, into which study the pupil gradually passes as winter approaches and flowers become scarce. Once started in Pereira or Royle, he works away, reminded at nearly every page of his work done in the summer, gathering knowledge as he reads, and has difficult passages explained, until he reaches the second or third winter, by which time he has gained in the shop sufficient acquaintance with trade chemicals to give an interest to chemistry.

A schedule, *drawn up by himself*, showing, in parallel columns, the symbols, equivalent numbers, and specific gravities of elementary substances is a great help to a student of chemistry; it should hang where it can be easily seen, and be learnt as perfectly as possible.

Structural botany may be read alternately with chemistry.

Practical pharmacy is best learned behind the counter.

I cannot too strongly recommend the practice of making notes whilst reading, and of asking for advice or explanation whenever it is needed. This shows a master that his pupil is trying to help himself, and promotes good feeling on both sides; let it be understood that apprentices may read when business permits, the earnest ones will find time for it without neglecting their other duties, and when the examiners' lists appear we shall see their names rank high "in order of merit."

Perhaps some of the examiners, past or present, will favour us with their opinion on this subject.

10, *High Street, Crediton, Devon, July* 31*st*, 1871. William Jackson.

The Pharmacy Bill.

Sir,—The statements made at the last meeting of Council by Mr. Groves, Mr. Smith and Mr. Sandford, as to the ignorance which prevails in the country upon the provisions of the late Pharmacy Amendment Bill, are singularly confirmed by the correspondence in the last two numbers of the Journal. Mr. Mayhew in the number for July 29th, and Mr. Bell in the current number, protest against the inspection threatened by that Bill! Would it surprise those gentlemen very much to learn that inspection is not so much as named in the Bill?

It is fair to assume that gentlemen, who have published forcible letters upon the subject, have taken a more than ordinarily intelligent interest in the course of events; and it is with no disrespect to them that I note their not insignificant mistake. Incredible as it may seem, I believe that a majority of the petitioners against the Bill were equally ill-informed as to its provisions, and that still greater misapprehension prevailed as to the negotiations of which the poison regulations were the sequel.

Loyalty to pharmacy will now be best shown by allowing excited feelings to subside, and to make way for calmer influences. When the atmosphere shall have recovered its natural serenity, there may still be an opportunity for conciliatory and united action before a new Bill can be submitted to Parliament. In the meantime, I would willingly assent to inspection—of the editorial sanctum—with despotic powers of fine and imprisonment, if you, Sir, should allow your good nature again so far to overcome your better instincts as to insert any more combustible correspondence.

I beg to conclude by moving "the previous question," viz. Scientific pharmacy,—too long banished from its happy home.

52, *Royal York Crescent, Clifton, August* 8*th*, 1871. Rich. W. Giles.

Sir,—In your last number Mr. Sandford refers to me at considerable length, and I must ask permission to reply. In his letter Mr. Sandford says, "When I look back to the narrow majority which the non-regulationists obtained at the Annual Meeting, I think we may still claim to represent our constituents." By the use of this argument Mr. Sandford says, just as if he declared it in more direct words, that he believes the division to which he refers was a trial of strength taken under fair conditions. Now, what are the facts? Firstly, that the opponents of the regulations protested, in the most definite manner, against the consideration of compulsory regulations at the Annual Meeting, because the Council and the Journal had assured the country members that compulsory regulations were withdrawn. But, secondly, the fact that that meeting could not consider compulsion, without a breach of good faith towards absent members, was shown by the speeches of the following gentlemen belonging to the pro-regulation party:—Mr. Mackay said, "I say it most emphatically, it would have been a much fairer course for the gentleman who has so ably and eloquently pleaded for this amendment, if due notice had been given of it."

Mr. M. then spoke as to deputations that would have attended had this been the case, and concluded most impressively thus,—"I say it is specially unfair, and I use the word with due consideration, to many country gentlemen, who are as deeply interested in this question as we are, to push the question of this amendment to a vote. So strongly do I feel upon this point, that if the amendment is pressed I may move the adjournment of the meeting."

The venerable Mr. Waugh spoke with great warmth upon the attempt "to steal a march," and concluded by begging that the amendment might not be passed. Mr. Randall was equally emphatic upon the impropriety of attempting to pass such a resolution at a meeting which had received no public notice of it. With such expressions from honourable opponents there can be no doubt as to the merits of the point in question. It is not for me to gauge the allowance due to those regulationists who, in the heat of argument, failed to see the limitation thus imposed; but some such allowance might be claimed for them, which is not due to the deliberate and repeated attempt to represent the vote of the Annual Meeting for something which it was not. This misrepresentation of the fact had been employed towards the Right Hon. W. E. Forster, and is reproduced in Mr. Sandford's circular of July 10. What can that cause be that requires such *suppressio veri* and *suggestio falsi?* I have now made good my late charge of employing "questionable means" so far as one argument is concerned.

Mr. Sandford has attempted to prove too much. He reminds one of the devoted fox-hunter, who argued for his favourite sport that "the men liked it, the horses liked it, the dogs liked it, and it wasn't quite proved that the fox didn't like it!" That there was no such special liking in the House of Commons for the Pharmacy Bill was sufficiently shown by the statement of the *Daily News,* that its withdrawal was received with general approbation.

As Mr. Sandford fears a state of "intolerable terrorism" as a consequence of our present simple form of representative government, it is only just to his forethought to say that he had anticipated its incompatibility with such paternal rule as he seems to think best for us. In the original Bill of 1868 a *coup d'état* was attempted, which would have changed the basis of the Society's government; and it was very late indeed when public attention was called to the fact that the Bill allowed to that 80 per cent. of the members belonging to the provinces just one-third of the seats at the Society's Council, whilst two-thirds were reserved for those who possessed the many graces consequent upon living within ten miles of the General Post-Office. The local secretaries stepped in at this critical period, and the revolutionary attempt was quietly thwarted; but whenever our representative system is discussed, this fact deserves record. I do not hesitate to say that the existence of various Associations, formed specially to agitate questions of trade policy, is a great evil; but at present it is a necessary one, and the constitutional corrective lies in the annual elections. It is more difficult to suggest a remedy for a representative who feels "terror" of his constituents.

I have been sometimes asked by opponents of the late Bill why we should not accept it, and freely use our power of amending schedule A, so that it should embrace only a few undoubted "poisons"? This is a very natural question, and the answer suggests new aspects of the subject. The reason why a sweeping reduction of schedule A would be impossible is, that it would practically destroy the prohibitive power of the Act of 1868. Where that Act forbids a man to use a particular title, it is of very little consequence, for probably the words "medical hall" over his door would bring him more pence. But when the Act forbids him to sell anything comprised in schedule A, its reality and the intention of Parliament to confine the sale of powerful medicines to a qualified class of men is shown. Suppose that you interpret schedule A as not including paregoric elixir (although that medicine has constantly caused the death of infants), the effect is to throw open the sale of paregoric elixir to every huckster in the kingdom, and thus defeat the intention of Parliament. It seems hardly credible that Mr. Sandford should, by treating paregoric elixir as not being a poison within the meaning of the Act, have contributed to defeat one great object of Parliament. As to the fact that we are all left in a state of doubt whether paregoric elixir is a legal "poison," and whether fines of £5 belong to it or not, I can only say that any future Bill open to such doubts will be quickly seen through in the House of Commons, although it may not be transparent to those who are wilfully blind.

Leeds, August 8th, 1871. RICH. REYNOLDS.

Sir,—Having carefully perused the interesting work by Sir Charles Bell 'On the Hand,' commended to me by Mr. Sandford, I am unable, although "we find every organ of sense, with the exception of touch, more perfect in brutes than in man," to entertain "the opinion of Anaxagoras, that the superiority of man is owing to his hand;" therefore I will, with your permission, endeavour to state more succinctly what I did mean in my former note. It is a great misfortune that theorists and men of great scientific attainments are apt to describe the common sense of ordinary men of business as "nonsense;" and as the "good deal of nonsense" that "has been talked" came chiefly from those who had only the practical knowledge of their business to guide them, I am not surprised at any contempt with which their utterances are regarded. I doubt not the majority of your readers understood that the education at the Square required by the Examiners was the check I alluded to, and the only kind needed to qualify a man to carry on his duties. If not, how is it mechanical arrangements, alarm bells, etc., are not included in the studies? It was stated by Mr. Forster that regulations would not be requisite, if all were educated up to the pharmaceutical standard.

Dr. Greenhow, in his report, considered the examinations "as practical as possible," and the President in his report at the last Annual Meeting read:—

"I have, in conclusion, only to repeat what has already been implied in my Report, that, in my opinion, the examinations of the Pharmaceutical Society are of such sort, and are conducted in such manner, as to constitute a sufficient guarantee to the public with regard to the qualifications of persons admitted to register under the Pharmacy Act, 1868."

This is the check which all friends of the Society have been striving to establish; but if the new signification is to be accepted, then a different order of intellect will be required, and probably a new "*Bell* scholarship" will be instituted, by which the sense of *hearing* would act as the sentinel of the brain.

In concluding with the following remarks, I believe I shall not be the first, by some hundreds, who have uttered similar "nonsense." That it is not to be wondered at, if those not of the trade should seek to bind on others mechanical substitutes for intelligence, but that those among ourselves, who are educated, should themselves endeavour to be chained up as dangerous individuals, and should provide their own fetters, seems an attitude at once humiliating and unaccountable.

August 8th, 1871. JOHN WADE.

Sir,—A word or two in reply to your editorial note in reference to the orthography of my letter to Mr. Smith. Writing hurriedly, and under pressure of many duties, I may have carelessly transposed some of my letters or made some mistake; but is it not a needless function for you to exercise to call attention to errors of this kind occurring in correspondence?

A word to Mr. Smith. This gentleman does not meet my charges, but takes refuge in impeaching my orthography. This doubtless indicates Mr. Smith's orthographical eminence, and demonstrates his innate gentlemanly nature and unusual refinement of disposition.

63, *Piccadilly, Manchester,* ROBT. HAMPSON.
August 8th, 1871.

W. F. C.—A formula for composition powder has been given before, vol. i. p. 457.

"*An Apprentice and Subscriber*" has not sent his name and address.

A. B.—Macmillans.

"*Veuve.*"—(1.) No. (2.) No.

Owen Jones.—(1) The practice is not illegal. (2.) The retailing of poisons by an unregistered person would be against the law, and the sale of poisons insufficiently labelled would be an additional offence.

M. P. S.—Those persons who passed the "Separate Examination for Chemists in business" were *not* supplied with diplomas similar to those awarded to successful candidates in the Major Examination.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. G. Brownen, Mr. R. Newall, Mr. J. Thompson, Mr. J. J. Thomas, Mr. A. W. Gerrard, Mr. Macmillan, Mr. R. Chessall, Mr. T. Griffin, Mr. W. R. Rednall, Mr. A. W. Bennett, Mr. W. H. Wilcox, Mr. J. Horsley, Mr. W. Wilkinson, Mr. Fairlie, Mr. Postans, G. R. C., "Minor Exam.," "One of the Candidates," "Galvanic," "An Apprentice."

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 102.)

SIDA MYLABRIS, *Mylabris phalerata*, Pall.; villous, black; elytra black, with three broad undulating rufescent bands; the first arising from two spots.—Pall. Ic. p. 78, t. E. f. 3 b. *Mylabris Sidæ*, Fabr. S. El. ii. p. 83; Brandt and Ratzb. ii. t. 18. f. 18; Billb. Mon. t. i. f. 1–5. Head black, punctulate, villous; antennæ black, brow impressed. Thorax longer than broad, black, villous, punctate, transversely impressed, the impression in the middle punctiform, the other at the base broader. Scutellum small, black, punctate; elytra three times as long as broad, punctate, black; with two undulating bands and two rufescent spots at the base, the spot by the scutellum rounded, that at the margin oblong. Wings hyaline, with tawny veins. Breast and abdomen black, villous, punctate. Feet black, villous.

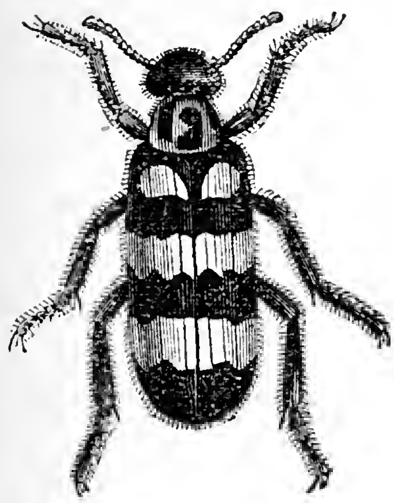

Fig. 2.—*Mylabris phalerata.*

Found on species of *Sida*, *Hibiscus*, etc.

This species is a native of the Cape of Good Hope, China, etc., and forms a portion of the commercial article exported from China. According to Soubeiran, it is largely employed in Germany, where it is imported by English merchants. The bands are reddish-brown, and *not* ochraceous-yellow, as in the chicory *Mylabris*. It is figured by Pallas, as cited above, and in Billberg's 'Monograph,' t. 1. f. 1–5. The greater portion of the "Chinese Fly" imported into this country has consisted of the present species, which is generally much larger than *M. cichorei*. It seems probable that the remarks of Indian observers, in so far as they refer to the Telini fly feeding on *Sida* and *Hibiscus*, belong to this species.

FOUR-SPOTTED MYLABRIS, *Mylabris melanura*, Pall.; villous, black; elytra reddish-brown, or yellowish, with four spots, black at the apex, the inner margin of apical band sinuated.—Pall. Ic. p. 86. *M. quadripunctata*, Tausch. Mem. Mosc. p. 133. t. x. 2; Billb. Mon. t. iii. f. 7–12. *M. cichorii*, Oliv. c. iii. p. 7. t. ii. f. 13. Head black, villous, punctate. Thorax scarcely longer than broad, black, villous, punctate. Scutellum black, villous. Elytra three times as long as broad, punctate, with rudimentary elevated lines; subvillous, yellowish or reddish brown, with four spots; two anterior, one at the suture, the other at the margin, and two posterior, behind the middle, one at the suture rounded, the other at the margin subquadrate; the apical band black with the anterior margin sinuate. Almost the size of *M. variabilis*.

It is a native of Spain and Russia. According to the Pharmacopœia of India it extends also to that country, being cited as one of the indigenous species. It is figured in Billberg's 'Monograph,' t. iii. f. 7, 8, as well as in the 'Moscow Memoirs,' and by Olivier as cited above.

This species can be easily distinguished from the foregoing by the four spots on the elytra. It is smaller than the *Sida Mylabris*, or the majority of the chicory *Mylabris*, and would seem to be less common than either, since it is rare to find a specimen mixed with the commercial 'Chinese Fly."

BANDED MYLABRIS, *Mylabris balteata*, Pall.; villous, black; elytra black, with two broad bands, the outer tawny, the inner yellow with a black spot.—Pall. Ic. 1781, t. H. f. E. 14. *M. punctum*, Fabr. S. El. ii. p. 84; Billb. Mon. t. ii. f. 15–18. *M. Indica*, Fuessly, Arch. t. xxx. f. 6; Oliv. iii. pl. 2, 19. *M. fasciata*, Voet, Cat. Col. p. 20, t. 48, f. 2. *a*. Head black, villous, punctate; thorax a little longer than broad, black, villous, punctate. Scutellum black, punctate. Elytra three times as long as broad, punctate; puncta small, in four longitudinal elevated lines, glabrous, black; with two broad bands one yellowish, with a black point in the middle, the other and posterior band tawny; wings hyaline. Breast and abdomen black, subvillose, punctate. Feet black, subvillous.

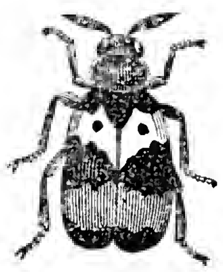

Fig. 3.—*Mylabris balteata.*

Native of the East Indies. According to Dr. Collas ('Moniteur Officiel,' Pondicherry, March 2, 1855), it is one of the species which have been successfully employed in Pondicherry, and as such is quoted by Moquin-Tandon.

This is easily recognized by the different colour of the two transverse bands on the elytra, that nearest the apex being of a darker colour; and also by the little black spot on the lightest band on each elytron.

WAVED MYLABRIS, *Mylabris pustulata*, Thunb.; villous, black; elytra black, with two spots and two narrow bands, of a dark blood-red, deeply dentate. —Thunb. N. I. sp. vi. p. 113, T. f. 13; Oliv. iii. t. i. f. 10 b.; Billb. Mon. t. 1. f. 6. *M. undulata*, Herbst, Fuess. p. 179, t. 48, f. 3. Head black, punctate, villous; front impressed; antennæ black. Thorax half as long as broad, punctate, villous, black. Scutellum black, punctate. Elytra three times as long as broad, punctate; puncta in deep bands, subvillose, black; with two spots, one at the suture rounded, the other at the margin oblong; and two narrow dark blood-red bands, the anterior band undulated, the posterior deeply dentate. Wings hyaline. Breast and abdomen black, punctate, villous. Feet black, villous. Almost the size of *M. phalerata*.

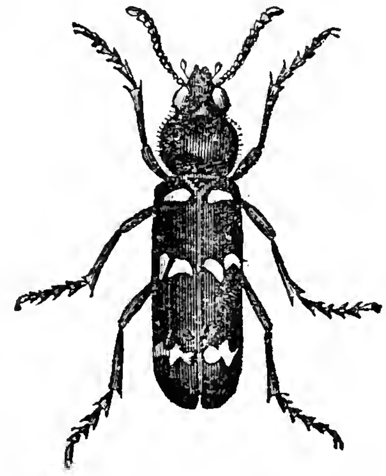

Fig. 4.—*Mylabris pustulata.*

Native of the Cape of Good Hope, China and Bengal. According to Dr. Collas, this is one of the species which has been employed successfully in Pondicherry, upon whose authority it seems to have been quoted in the Pharmacopœia of India.

This is not so easily distinguished from the *Sida Mylabris* by a non-professional eye as the other Asiatic species. The bands are much narrower, and of a deeper-blood-red, and it is fully its equal in size.

EYELET MYLABRIS, *Mylabris oculata*, Oliv.; subvillous, black; elytra black, shining; with an ochraceous spot at the base and two bands, the hindmost rounded at the apex.—Oliv. Ent. iii. p. 47. t. 2. f. 11 *a b*; Billb. Mon. t. v. f. 6–10. *Meloe oculatus*, Thunb. N. Ins. Sp. vi. p. 114. *M. plagiata*, Pall. Icon. t. E. f. 3 *a*. Head black, somewhat hairy, punctate; antennæ black, the six ultimate articulations tawny. Thorax scarcely longer than broad, black, rather hairy. Scutellum black, punctate. Elytra three times as long as broad, roughly punctate with four elevated longitudinal lines, shining, black. Spots at the base rounded, ochraceous, and two bands of the same colour, the one before the middle somewhat arched, and the hindmost, below the middle, the space between chestnut. Breast and abdomen black, somewhat hairy, punctate. Feet black.

Native of the Cape of Good Hope and Bengal. In the variety found in Bengal the basal spot forms a short band. The size is equal to that of *M. phalerata*, from which it is not always easy to distinguish some of its forms. Although this is not recorded in the Indian Pharmacopœia, it is doubtless mixed indiscriminately with other species.

Channelled Mylabris, *Mylabris humeralis*, Walk.; black, elytra with two humeral furrows, two basal yellow spots, and two angular bands; length 9 to 11 lines.—Walker, Ann. Nat. Hist. Ser. iii. vol. ii. p. 285.

The typical insect described by Walker is in the British Museum Collection, and was from Ceylon. This is, however, one of the indigenous species cited in the Pharmacopœia of India.

Oriental Mylabris, *Mylabris orientalis*, Mars.

We cannot find that this species has been described; it is included in Gemminger and Herold's catalogue, and appears to have been one of the species recognized by Marseul in his 'Monograph,' submitted to the Entomological Society of France in 1870, with the citations of Dejean's Catalogue III. ed. p. 244. The locality quoted is the East Indies, and it is enumerated in the Pharmacopœia of India as one of the indigenous vesicants. Beyond this we can furnish no information or description, and must rest content with waiting until the promised publication of Marseul's 'Monograph.'

Mylabris proxima?

One of the species cited as indigenous in the Pharmacopœia of India; but, beyond this, we find no mention of the name, or any description answering thereto.

This completes the list of species belonging to the genus *Mylabris*, of which we have any certain knowledge that they are employed as vesicants in Asia. When the *Coleoptera* of China and India are better known, it may be presumed that there, as in the Archipelago, other equally good vesicants will be discovered.

PRESERVATION OF TINCT. KINO FROM GELATINIZING.

BY J. W. WOOD.

Among all our tinctures, perhaps there is not one so liable to deteriorate by exposure, or by long keeping, as tincture of kino, made in accordance with the U. S. Pharmacopœia; its well-known property of gelatinizing in a short time—a property which yet remains to be investigated—being thereby rendered inert, precludes it from being as extensively used as its virtues would seem to warrant.

This property renders it inadmissible when we desire a reliable tincture, to prepare it in large quantities.

The Pharmacopœia formerly directed it to be prepared with dilute alcohol as the menstruum; but later it was thought to be of advantage to increase the proportion of alcohol to two-thirds; yet it is doubtful if there was much gained by this change.

I would therefore submit the following mode of preparation, which I consider, from the experience I have had, will meet with the desired end, and up to the present time results do not seem to disprove it. It is as follows:—

℞ Kino in fine powder, ℥iss
Alcohol ·835, f℥viij
Water f℥iv
Glycerine, f℥iv.

Mix the alcohol, water and glycerine together, and having mixed the kino with an equal bulk of clean sand, introduce in a percolator and pour on the menstruum.

This menstruum seems to thoroughly exhaust the drug of its astringent principle, and also makes a nice-looking preparation.

Some which I made on the 16th day of July, 1870, was exposed to the influence of the atmosphere, the stopper of the bottle containing it having been removed for several months, so that it had evaporated to at least two-thirds; yet it remains as good as when freshly made, without any apparent tendency to gelatinize.

The menstruum might be somewhat modified, perhaps with advantage, as, for instance, by using proportionally less alcohol and more glycerine and water, or *vice versâ*. At any rate I will give it for what it is worth; adding at the same time the suggestion—and it is only a suggestion—that the same menstruum be employed in preparing tinct. catechu, which, though not so liable to gelatinize as tinct. kino, yet sometimes does so.—*Amer. Journ. Pharmacy.*

PHARMACY IN THE REPUBLIC OF CHILI.

Dr. J. N. Ullersperger, of Munich, furnishes some interesting information on the state of pharmacy in Chili, from which we learn that the war of 1866 against Spain had a most unfavourable influence upon it. The President of the Sociedad de Farmacía—which, it seems, represents science in all its branches—reported to the Minister that the Society had endeavoured to keep up its connection at home and abroad, and also to commence several investigations; but the latter progressed but slowly, as the subsidies voted by the national congress were applied to war purposes, in consequence of which the publication of the journal had also to be suspended. Nevertheless, the society managed to keep open their laboratory, to discuss and to ripen a plan for raising the pharmaceutical studies to the level of the demands of modern science, and finally to take preliminary steps for the compilation of a Pharmacopœia. The Society had also continued to take meteorological observations in different parts of the republic; they had received several memoirs, collected information on several plants of the country, and otherwise shown active signs of their existence;

they looked well after the army dispensaries, and collected much statistical information hitherto greatly neglected.

At the end of the war, in 1867, matters had somewhat resumed their former regularity, and especially the different branches of the university seem to have done their best to advance scientific life and interest. In the botanical department, Don R. A. Philippi published a fresh report on Father Feuillée's valuable work, 'Las Plantas Chilenas,' a record of travels in Chili and Peru in the years 1709 to 1712. Don T. Domeyko, professor of mineralogy, sent in analyses of several Chilian minerals; while in zoology Don R. A. Philippi supplied a critical commentary.

At a meeting of the Council of the University in March, 1867, it was decided to adopt as textbook for public instruction Don Anjel Vasquez' treatise entitled 'Tratado de Química Orgánica, con aplicacion á la Farmacía y Medicina;' clearness in the exposition of matters, complete study of organic chemistry, enlargement of the parts treating of animal chemistry, were given as special recommendations. But, unfortunately, the necessary funds for printing the book, which the university had to find, were not forthcoming, and the publication had to be postponed.

In October, 1867, the Dean of the Medical Faculty, Don Ceslao Diaz, submitted a plan for regulating the pharmaceutical education, entitled, 'De Estudios para los Aspirantes á la Profesion de Farmacía;' and a month later the Dean, Don I. I. Aguirre, proposed certain regulations by which the exercise of pharmacy and the sale of medicines and drugs are properly limited, and by which the pharmacist has seemingly acquired a proper legal status. This—'Reglamento para el Ejercicio de la Profesion de Farmacía, venta de Medicinas y Drogas'—treats of the medicines and of those who are entitled to sell them; of the exercise of pharmacy; of the Pharmacopœia and the lists of officinal substances; of the visitation of pharmacies; of the sale of drugs; and of the fines in case of contraventions. The list of natural and chemical products exclusively medicinal, and which drysalters or druggists are allowed to sell only wholesale, and without previous preparation, comprises 238 substances; poisons which non-pharmacists are not allowed to sell without special precautions, such as registering the names of buyers, intended use of poisons, etc., are 88 in number; and the list of medicinal non-poisonous plants, the sale of which is free, contains 86.

Besides these regulations, there are a number of restrictions, issued by the medical police, to which the pharmacist is bound to submit. The conditions of the study of pharmacy for apprentices or assistants are twofold; they refer to the number of years required for a pharmaceutical course, and to the different branches of study. Ten years are prescribed, the first five for school training, and the following five for special studies, viz. 1st year, inorganic chemistry and botany; 2nd, organic chemistry, analyses of drugs and medicines, zoology; 3rd year, analyses as before, materia pharmaceutica; 4th year, practical pharmacy, comprising chemical pharmacy, dispensing of medicines, officinal substances, and study of formulas and prescriptions; 5th year, legal pharmacy, including theoretical and practical toxicology, study of the Pharmacopœia, and again investigations of drugs and medicines.

In 1868 there were eighteen students, "aspirantes á la profesion de farmacéutico," at the University of Santiago.

THE GASEOUS AND LIQUID STATES OF MATTER.

BY THOMAS ANDREWS, M.D., F.R.S.,

Vice-President of Queen's College, Belfast.

The liquid state of matter forms a link between the solid and gaseous states. This link is, however, often suppressed, and the solid passes directly into the gaseous or vaporous form. In the intense cold of an Arctic winter hard ice will gradually change into transparent vapour without previously assuming the form of water. Carbonic acid snow passes rapidly into gas when exposed to the air, and can with difficulty be liquefied in open tubes. Its boiling-point, as Faraday has shown, presents the apparent anomaly of being lower in the thermometric scale than its melting-point; a statement less paradoxical than it may at first appear, if we remember that water can exist as vapour at temperatures far lower than those at which it can exist as liquid. Whether the transition be directly from solid to gaseous, or from solid to liquid, and from liquid to gaseous, a marked change of physical properties occurs at each step or break, and heat is absorbed, as was proved long ago by Black, without producing elevation of temperature. Many solids and liquids will for this reason maintain a low temperature, even when surrounded by a white-hot atmosphere, and the remarkable experiment of solidifying water, and even mercury, on a red-hot plate, finds thus an easy explanation. The term spheroidal state, when applied to water floating on a cushion of vapour over a red-hot plate, is, however, apt to mislead. The water is not here in any peculiar state. It is simply water evaporating rapidly at a few degrees below its boiling-point, and all its properties, even those of capillarity, are the properties of ordinary water at 96·5 C. The interesting phenomena exhibited under these conditions are due to other causes, and not to any new or peculiar state of the liquid itself. The fine researches of Dalton upon vapours, and the memorable discovery by Faraday of the liquefaction of gases by pressure alone, finished the work which Black had begun. Our knowledge of the conditions under which matter passes abruptly from the gaseous to the liquid, and from the liquid to the solid state, may now be regarded as almost complete.

In 1822 Cagniard de la Tour made some remarkable experiments, which still bear his name, and may be regarded as the starting-point of the investigations which form the chief subject of this address. Cagniard de la Tour's first experiments were made in a small Papin's digester, constructed from the thick end of a gun-barrel, into which he introduced a little alcohol and also a small quartz ball, and firmly closed the whole. On heating the gun-barrel, with its contents, over an open fire, and observing from time to time the sound produced by the ball when the apparatus was shaken, he inferred that after a certain temperature was attained the liquid had disappeared. He afterwards succeeded in repeating the experiment in glass tubes, and obtained the following results:—An hermetically-sealed glass tube, containing sufficient alcohol to occupy two-fifths of its capacity, was gradually heated, when the liquid was seen to dilate, and its mobility at the same time to become gradually greater. After attaining to nearly twice its original volume, the liquid completely disappeared, and was converted into a vapour so transparent that the tube appeared to be quite empty. On allowing the tube to cool, a very thick cloud was formed, after which the liquid reappeared in its former state.

It is singular that in this otherwise accurate description, Cagniard de la Tour should have overlooked the most remarkable appearance of all, the moving or flickering striæ which fill the tube when, after heating it considerably, the temperature is quickly lowered. This phenomenon was first described by myself in 1863, as it is seen in carbonic acid which has been partially liquefied by pressure, and afterwards heated a little above 31°. It may be observed on a larger scale and to great advantage by heating such liquids as sulphurous acid or ether in hermetically-sealed tubes.

The experiments whose results I am about to describe have occupied me for a period of fully ten years; they involved the construction of novel forms of apparatus, in which the properties of matter might be studied under varied conditions of temperature and pressure, such as had never been realized before. In my earlier attempts I endeavoured, as others had already done, to use the expansive force of the mixed gases which are disengaged in the electrolysis of water; and I was able in this way to obtain pressures of 150 atmospheres and even more in glass tubes; but the method was in many respects defective, and more than one dangerous explosion occurred, so that I eventually abandoned it.

In the apparatus finally adopted, the gas to be compressed is enclosed in a long glass tube, of which the greater part of the length, or about 450 millimetres, has a capillary bore, and the remainder, about 150 millimetres, an internal diameter of 2 millimetres. The free capillary end is sealed, while the gas in a pure and dry state is passing through; while at the other end the gas is confined by a movable column of mercury. The details of the method by which this is accomplished will be found in the Bakerian lecture for 1869, to which I must also refer for an account of the process by which the original volume of the gas at the freezing-point of water and under one atmosphere of pressure was determined, and also the volumes of the same gas deduced from the observed measurements when it was compressed at different pressures in the capillary tube.

A conical protuberance on the capillary part of the tube, a little above its junction with the wider part, corresponded as nearly as possible with a hollow cone in a stout brass flange, the joint being rendered perfectly tight by careful packing. The body of the apparatus consisted of two cold-drawn copper tubes of great strength, to the ends of which four massive brass flanges were firmly attached. Two corresponding flanges or end pieces, each carrying a fine steel screw packed with great care, were bolted on the lower flanges. The success of the experiments depended greatly on the packing of this screw. It was effected by means of a number of leather washers, tightly pressed down and saturated *in vacuo* with melted lard. The apparatus was now filled with water; the flanges with the glass tubes, one containing the gas to be examined, the other air or hydrogen to act as a manometer or measure of the pressure, were bolted down upon the upper flanges of the copper tubes. The joints had always leather washers interposed; and when sufficiently tightened, they resisted any pressure which could be applied, even for an indefinite time. The two copper tubes were connected by a fine horizontal tube, so that the whole of the interior of the apparatus was in free communication. The pressure was obtained by screwing one or other of the steel screws into the water. I have recently had the apparatus constructed of iron and filled with mercury. As mercury is much less compressible than water, the same length of screw produces a greater pressure on the interior of the apparatus, even with a larger cavity. There are other advantages in this form of the apparatus which I hope will facilitate future research. The objection to it is its extreme sensitiveness to changes of temperature, so that a variation of $\frac{1}{100}$th of a degree alters the internal pressure by several atmospheres.

In the actual experiments the gas under examination does not come into view till it has entered the capillary tube, and is exposed to a pressure of thirty or forty atmospheres. The limit of the pressure which can be obtained has hitherto been the capacity of resistance of the glass tubes to bursting. Fine thermometer glass tubes of white glass will frequently burst when exposed to a pressure of little more than 100 atmospheres; but green glass tubes of good quality are much stronger, and will easily bear a pressure of 300 atmospheres. One of the strongest forms of glass capillary tube for resisting internal pressure is obtained by drawing out a thick, green glass tube, heated to softening, till it becomes so fine as to be flexible. Tubes of this kind can easily be drawn out at the blowpipe table, and obtained of very uniform bore. I have compressed air in such tubes to $\frac{1}{400}$th of its ordinary volume without bursting the tubes.

Two rectangular brass cases, closed before and behind with plate-glass, surround, one the manometer, and the other the tube containing the gas to be examined, and allow them to be maintained at any required temperature by the flow of a stream of water. The manometer was maintained as nearly as possible at the temperature of the apartment; the tube containing the gas, on the contrary, was maintained at different temperatures, according to the object in view. The following observations, published in 1863, contain the results of my earliest experiments on this subject:—"On partially liquefying carbonic acid by pressure alone, and gradually raising the temperature at the same time to 88° Fahr., the surface of demarcation between the liquid and gas becomes fainter, loses its curvature, and at last disappears. The space is then occupied by a homogeneous fluid, which exhibits when the pressure is suddenly diminished or the temperature slightly lowered, a peculiar appearance of moving or flickering striæ throughout its entire mass. At temperatures above 88° no apparent liquefaction, or separation into two distinct forms of matter, could be effected, even when a pressure of 300 or 400 atmospheres was applied. Nitrous oxide gave analogous results."

The flickering striæ referred to can be admirably shown, as I mentioned before, in hermetically-sealed tubes of strong glass, partially filled with such liquids as sulphurous acid or ether. The liquid must in the first instance be heated a few degrees above what I have designated the "critical" point. The appearances exhibited by the ascending and descending sheets of matter of unequal density are most remarkable, but must be seen in order to be understood. They only occur in this striking form in fluids heated a little above the critical point, and are produced by the great changes of density which slight variations of pressure or temperature produce in this case. They are always a clear proof that the matter in the tube is homogeneous, and that we have not liquid and gas in presence of one another. These striæ are in short only an extraordinary development of the movements seen in ordinary liquids and gases when they are heated from below. The experiments to be immediately described will explain their great intensity above the critical point.

When the temperature falls below the critical point, the formation of a cloud indicates that we have now heterogeneous matter in the tube, fine drops of liquid in presence of a gas. We must take care, however, not to suppose that a cloud *necessarily* precedes the formation of true liquid. If the pressure be sufficiently great, no cloud of any kind will form.

I now proceed to describe the general results of the experiments upon carbonic acid. If a certain volume of carbonic acid at the temperature of 13°·1 and under a pressure of one atmosphere be exposed to a gradually-increasing pressure, its volume will steadily diminish, but at a faster rate than according to Boyle's law, till at the pressure of 48°·9 atmospheres its volume is reduced to about $\frac{1}{81}$st of the original volume at one atmosphere. Liquefaction now begins and continues with very slight augmentation of pressure, the necessity for which I traced to the presence of a minute quantity of air (about $\frac{1}{500}$th part) in the carbonic acid. On augmenting the pressure after liquefaction, the volume slowly diminished, but at a much faster rate than in the case of ordinary liquids. Later experiments carried to much higher pressures have fully confirmed this result. At 21°·5 similar results were obtained, but a pressure of nearly 60 atmospheres was required before liquefaction began.

At 30°·9 C., or 87°·7 Fahr., the critical point of temperature is reached. It is the temperature at which liquid ceases to be formed under any pressure. At a temperature a little below this point the surface of separation between liquid and gas becomes very faint and loses its curvature, the density and other physical properties of the liquid and gas being now identical and the tube filled with homogeneous matter. If the temperature and pressure be kept steady, no evidence of heterogeneity will be obtained by optical tests under the most varied conditions of volume.

If we now follow the course of a given volume of carbonic acid gas at 31°·1, or 0°·2 above the critical point, we shall find that its course resembles that of the gas at lower temperatures till the volume is reached at which liquefaction might be expected to begin. A rapid but not (as in the case of the formation of liquid) abrupt fall then supervenes, after which the carbonic acid undergoes a slow diminution of volume as the pressure augments. The curves, which are here exhibited as they were represented in the Bakerian lecture, illustrate very clearly these statements. We have thus carbonic acid at 0°·2 above the critical point, and at a pressure of 73 atmospheres behaving very nearly as if it liquefied. At this pressure an augmentation of only $\frac{1}{37}$th of the entire pressure diminishes the volume of the carbonic acid to about one-half. Yet during the whole of this fall, no evidence of heterogeneity, or of two states of matter present together in the tube, could at any period be obtained. Carbonic acid at this temperature of 31°·1, and under a pressure of 75 atmospheres, behaves much more as a liquid than as a gas when the pressure is either augmented or diminished; yet it never exhibits under any conditions the characteristic properties of the liquid state; that is to say, no surface of separation is formed by change of pressure, nor will it collect into drops and form a cloud.

(To be continued.)

SOME MEDICINAL PLANTS OF CANADIAN GROWTH.

BY W. SAUNDERS, LONDON, ONTARIO.

Having become somewhat debilitated by close application to business, I purchased two years since a farm with the intention of planting it with fruits of various sorts, and growing as well such varieties of foreign and indigenous medicinal plants as should be found suitable to the soil and climate. The personal supervision requisite to begin and carry out successfully an undertaking of this sort would, I knew, oblige me to be away much from the shop, and exchange its closer atmosphere and sedentary occupations for the more active employments and purer air of the country. I believe, as a class, we pharmaceutists are fond of our profession, and there are charms as well as ties about it which seem to draw one naturally into long hours of steady application. It requires a considerable effort to break away from these influences, and unless one is obliged to do so, good resolutions are often set aside to suit occasion and convenience. My undertaking may not, at present, be regarded as a paying one; but there will surely be a large sum to place to the credit side on account of improved health and increasing vigour,—more than sufficient, I think, to balance any losses which may arise; and in this way at least I can recommend it to my fellow-pharmacists as a profitable enterprise.

This being the second season only for the new business, it is impossible to present any very full or complete details as to the success and profits attending the growth of the various medicinal articles, for, besides the time being too short, the seasons have both been very unfavourable. We have had such excessive rains that the ground has been almost saturated with water during a great part of the growing period; still I hope that the few results I am able to communicate will not prove uninteresting.

The first and one of the greatest difficulties was the procuring of suitable seeds, fresh and good; there is so little demand for such that they are sometimes old and almost worthless before they come into the purchaser's hands, so that very few of them will germinate. Some of the needed articles were found among the seed dealers of New York and Boston, others were obtained from the establishment of Vilmorin, Paris, France.

ATROPA BELLADONNA.

Two ounces of seed was planted, late in May, in drills of $2\frac{1}{2}$ feet apart, and covering 1-16th of an acre of ground, with the intention of transplanting it into rows, at suitable distances, the following season. The plants came up moderately thick, and attained a fair growth before the close of the summer; in one or two instances flowers appeared on them late in September. The outer leaves were partially stripped before severe frost came, carefully leaving the crowns uninjured. The product yielded 11 lb., when dry. Thinking that the plants were sufficiently vigorous and well established to withstand the cold of winter, they were not in any way protected. The season proved too severe for them, the following spring showing every plant dead, with its roots quite rotten.

From the herb gathered in the fall some preparations were made—fluid extract and solid extracts, watery and alcoholic. On comparison with similar preparations from like quantities, and made with equal care from a fair sample of the imported herb, the following results were noted:—

1 lb. of herb of Canadian growth yielded of solid aqueous extract, 2 oz. 7 drs. 23 grs.	1 lb. of imported herb yielded of solid aqueous extract, 3 oz. 5 drs. 10 grs.
Solid alcoholic extract, 1 oz. 5 drs. 25 grs.	Solid alcoholic extract, 2 oz. 2 drs. 30 grs.

Showing a difference of yield in favour of the imported herb of 5 drachms 47 grains aqueous extract, and 5 drachms and 5 grains alcoholic extract.

The fluid extract made from the herb of Canadian growth has the narcotic odour of the plant in a higher degree than that from the imported herb; the odour is so strong in the former case that it approaches pungency. It has been used in a few cases in practice, and as far as I have been able to ascertain, has acted fully as well as that made from the foreign plant.

The solid aqueous extracts closely resemble each other in odour, although I am inclined to regard that from the Canadian plant as strongest.

The alcoholic extracts differ in odour very materially; that from the herb of Canadian growth is much heavier and more powerful than the other. I have had no opportunity of having these latter articles tested in medical practice.

HYOSCYAMUS NIGER.

One ounce of seed in this instance was planted at the same time and in the same manner as that of the belladonna, occupying a space of less than 1-20th of an acre. The plants came up thin, a large proportion of the seeds failing to germinate. Ten pounds of leaves were gathered about the 1st of October. Some of the plants belonged to the annual variety, others to the biennial; most of the latter, in this instance, stood the winter well and sprouted out vigorously on the opening of spring, but the land where they were established being required for other purposes, they were transplanted. The place selected for their removal was rather low, and the wet season proved very unfavourable for their establishment; hence during the summer the larger part of the plants died; the few survivors were left for seed.

This plant has become naturalized, and is now growing wild in many parts of Canada, so that there is little doubt but that its culture, if desirable, might be made successful. A series of preparations have been made, in this case, similar to those made from belladonna, with results as follows:—

1 lb. of herb of Canadian growth yielded of solid aqueous extract, 2 oz. 6 drs. 4 grs.	1 lb. of imported herb yielded of solid aqueous extract, 3 oz. 4 drs. 44 grs.
Solid alcoholic extract, 1 oz. 3 drs.	Solid alcoholic extract, 2 oz. 2 drs. 50 grs.

Showing a difference of yield also in favour of the imported herb of 6 drachms 40 grains aqueous extract, and 7 drachms 50 grains alcoholic extract.

The odour of the fluid extracts seems exactly alike; that from the aqueous extracts is also similar, although the advantage seems to rest with the Canadian article; while the alcoholic extracts again differ materially, the foreign article having the weaker odour.

The culture of *Digitalis purpurea* has not been attended with much success. A good quantity (2 oz.) of seed has been sown; but either the seed has been worthless, or it has been sown too deep, so that very few plants have appeared. Some of those grown last year survived the winter without protection, but many of them died. Seed sown this year has also come up very sparingly.

Dill was tried last season without success; the plants grew well and flowered, but the season proved too short for the seed to mature. Besides, it was almost destroyed by the attacks of a small caterpillar, which affects nearly all the umbelliferous plants with us. It is the progeny of a pretty little moth called *Depressaria Ontariella*. This little creature feeds on the unopened flowers, drawing the various portions of the umbel together with threads of silk, soon disfiguring and destroying them. Had the seed ripened, three-fourths of the crop would probably have been lost from this cause.

Fenugreek was also tried. It came up very thick, and did well; its peculiar odour perfumed the air for some distance around the patch during the latter part of the season, but the seeds, which formed well in their long pods, did not ripen sufficiently to be of any value. Better success attended the growth of coriander and caraway. One-eighth of an acre of coriander, with half a pound of seed, yielded 110 lb.; and one-fifteenth of an acre of caraway, with half a pound of seed, 106 lb., the corianders maturing their seed the same season that they were planted; the caraways not maturing till the second year.

Many other of the common herbs have been successfully grown, including wormwood, sage, hyssop, thyme, rue, horehound, rosemary, summer savory, poke-root and elecampane. Seeds of leptandra and glycyrrhiza germinated well, but the growth of both has been weak.

A quarter of a pound of dandelion seed has been sown this season on about three-fourths of an acre of ground. The plants have made very good growth, the roots having already attained about half an inch or more in diameter, and will probably acquire size sufficient to give a profitable yield before the close of the season.

The following includes most of the complete failures, that is, when the seed did not germinate at all:—*Arnica montana, Veratrum album, Gentiana lutea, Aconitum Napellus, Angelica, Solanum Dulcamara, Colchicum autumnale, Bryonia alba* and *Polygala Senega*.—*Proceedings of the American Pharmaceutical Association.*

PAROCHIAL CHEMISTRY.

That chloride of calcium and many other salts absorb water from the air, and that aqueous solutions of such salts will not dry up at the ordinary temperature of the atmosphere, even in summer, are facts so certain and so familiar as to have wellnigh acquired, in the estimation of chemists, the rank of necessary truth.

We learn that a civil engineer, in the employ of one of the London vestries, has made the discovery that a solution of deliquescent chlorides dries up as fast and as completely as pure water when exposed to the action of the summer sun. The locality in which so important an observation was made is the parish of St. George's, the occasion being the laying down of Mr. Cooper's deliquescent salts in the streets of that parish. We understand that the labourers employed under the distinguished engineer in question have made the still more remarkable observation that these deliquescent salts accelerate the evaporation of water. It appears that that which passes current among chemists relative to the properties of deliquescent salts is regarded by the eminent engineer in question as purely theoretical, as distinguished from his own observations and those of his men, who observe practical facts.—*The Lancet.*

Druggists' Shops in Djidda.—Djidda is the seaport of Mecca, and is little more than a day's journey from that famous city. Its trade, for an Eastern town, is considerable, and frequently forty or fifty ships may be counted lying together in its harbour. Some of the best shops in Djidda are those belonging to druggists, who do a lucrative trade. They are chiefly from India or of Indian descent. Besides dealing in all sorts of drugs, they sell candles, sugar, perfumery and incense, which is much used by the wealthy inhabitants, who perfume their best rooms every morning. For this purpose mastic and sandal-wood burnt upon charcoal are in great request. Coffee is rarely drunk in private houses without an admixture of cardamoms or cloves, and spices of all sorts and red pepper form an essential ingredient of most dishes. Another article of trade is rosebuds, which are brought from the Gardens of Tayf. The people of the Hedjaz, especially the ladies, not only steep them in the water used for their ablutions, but boil them with sugar and make a preserve of them.—*Food Journal.*

Sulphur in the Province of Caltanicetta, Sicily.—The following extract is taken from a report sent by M. Thibaudier, of the French consulate at Palermo, to the Minister of Foreign Affairs, 20th January, 1870. In the province there are altogether about 134 mines at work, which employ 11,000 workmen, and produce 105,350 tons of sulphur. This is almost entirely transported to the coast by means of mules, and is shipped from the ports of Girgenti, Catane, Terranova and Licata. The price varies from twenty-two to fifty francs per ton. The principal mines of the province, either from the development which they have already obtained, or from the importance that they are likely to acquire in a short time, are in the mining district of Caltanicetta, viz. Trabonello Gebbria rossa, and Giordano (stretto); the Capo d'Arso and Floristella, in the Castro Giovani district; Gallitano, in the district of Mazzarino; Grottacalda, in that of Piazza; Sociale, in the Montedoro district; Solfare Grande, in the Sommatino district; and in the Riesi district, the mines of Solfara del fiume, Apaforte, and Stincone. Some of these mines already have a production of from five to eight thousand tons annually, as Trabonello, Capo d'Arso, Solfare Grande, Grottacalda, and Solfara del fiume. All the mines are capable of great development.—*Journ. Society of Arts.*

The Pharmaceutical Journal.

SATURDAY, AUGUST 19, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

HOSPITAL DISPENSING.

IN the Journal of the 20th August last year we took occasion to comment on this subject, making use of a casualty that had occurred at the Royal Free Hospital as our text. And we now recur to it for the purpose of reminding those interested, that the duties of a hospital dispenser are entirely different from those of a chemist pure and simple, both in the kind of work, and in the way that that work is, or ought to be, accomplished. Great and constant care is required in both these walks of life, but we take it that hospital dispensers, whether in 'Service' or civil institutions, appreciate too little the importance of sticking to orders, and of giving out nothing that is not strictly prescribed in 'black and white.' The dispensary of a large hospital is a field in which work must be done quickly as well as accurately, and there are a thousand and one temptations to the loose performance of duty. Hospital out-patients, particularly in the country, are by no means clever in receiving or understanding verbal directions, so that little or nothing on this head should be left to common sense. For, though a struggling and by no means civilized crowd of sick people, all fighting their way to the dispensary window, by no means conduce to a placid frame of mind, dispensers are not on that account exempt from the results of carelessness. And often, in the midst of the work of the out-patient department, sisters and nurses make continual verbal appeals for this or that draught, mixture, or extra, accompanied by the assurance that the written order shall be soon produced. Some nurses are careful and perfectly trustworthy, but according to our knowledge, belief, and experience, no hospital dispenser should give out a medicine or drug of any sort or kind without an authority *in writing*, from the responsible officers. We firmly believe that a strict adherence to this rule would save trouble and prevent serious misadventures; and we are sure that this is the very decided opinion of those who have had much experience in the administration of large public institutions. It is, of course, impossible to legislate with success for the wonderful eccentricities of stupidity; and we doubt very much whether yellow labels, triangular, or "knobbed" vials or all the ingenious machinery for the prevention of therapeutical casualties that have lately been introduced into practical pharmacy, avail much, where common sense and ordinary prudence are absent. A good hospital dispenser may do much useful service to the hospital with which he is connected, by keeping a wholesome check on the expenditure, and advising the administration as to how and where savings can be effected in the purchase of drugs. Medical men are seldom good financiers, and cannot be supposed to know much about the market value of the medicines that they prescribe. But these matters come fairly within the range of a dispenser's duties, and an officer who can recommend when and how to buy to advantage may be the means of economizing hospital funds in his own department to a very considerable extent. It may, perhaps, be thought that the above remarks refer only to a small section of our readers, but they are worthy the attention of all who are now, or who are likely to become, public officers, in that which is a very important branch of all hospital establishments.

CONDURANGO, THE NEW REMEDY FOR CANCER.

THE new reputed cure for cancer, condurango or cundurango bark, a report of an analysis of which was recently published in this Journal (p. 63), appears to be creating considerable interest in the United States. The *New York Tribune* says that the surprising results following its use in cases of cancer have caused a great demand for it, as many as twenty or thirty letters a day being received by Dr. BLISS, to whom a small quantity had been sent by the Ecuadorian minister, and as many more by the State department, asking for supplies of it. Amongst the cases quoted where benefit has followed from its use is that of the mother of Vice-President COLFAX, who it is stated, with less than five ounces of the condurango, has been nearly cured of a cancer, which it was expected would end her life within the year. Dr. BLISS, being convinced that condurango is a specific for cancer, sent an order for five hundred pounds to a business house in Guayaquil, but was informed that it was not an article of commerce, and not obtainable by the ordinary commercial methods. He has therefore dispatched his partner, Dr. KEENE, to Ecuador to obtain a supply; and in order to facilitate his mission, that gentleman was made the bearer of official dispatches to the Government of Ecuador, and furnished with letters of recommendation by President GRANT, Mr. COLFAX, Mr. FISH and other prominent persons.

Dr. KEENE writes that the task of obtaining the condurango is more difficult than was expected. The roads to the Loja district are rough and unfrequented, the rainy season is not yet over, the streams are swollen, and dangerous to cross, and the Indians are disposed to throw every obstacle in the way of foreigners, of whom they are deeply jealous. However, when he wrote he was on the point of starting for the interior, and was confident of procuring a supply, in season for it to reach early in August. On arriving in the Loja district he will hire a force of Indians to gather the plant, and bring it down from the mountains, where it grows at points so high as to be inaccessible to beasts of burden. It will then be packed on mules, and transported to the coast. Dr. Keene found that orders for condurango had been received at Guayaquil from persons in England, France, Italy and other countries, to the Governments of which the Government of Ecuador had furnished samples.

On the other hand, there are evidently those who have doubts concerning the reputed virtues of condurango. The American correspondent of the *Times*, writing from Philadelphia, says:—

"Reference has been made to the condurango plant of Ecuador, an alleged remedy for cancer, to which the attention of the United States' Government was called in an official communication from the American Minister in that country. Tho samples of the plant sent here were distributed by the State Department as an efficient remedy, and a physician was quoted as having experimented with it, and vouched for its healing powers. But it appears that a board of physicians have been conducting experiments in Washington at the hospitals, and, although they have made no final report, yet their judgment, so far as the experiments have gone, is against the plant, which is said to be entirely inefficacious. A decoction of the wood of the condurango is used, but careful analysis fails to show that it has any unusual properties. The bark contains an insoluble gum, but no recognized medicinal principle. Both the wood and the bark have been subjected to minute examination, and are pronounced worthless. The patients afflicted with cancer who have been placed under treatment with condurango are said to fail to show any improvement in condition. There are hints that the stir which has been created about this alleged remedy was a part of a well-laid plan to get extensive advertising for a new quack medicine, for which a patent has already been obtained, and of which condurango is an ingredient."

Whatever truth there might be in the suggestion of this writer, it is evident that he has very hazy ideas as to what is meant by the commonly-used but erroneous term, "patent medicine."

WRITERS ON SCIENCE.

At the recent Literary Fund dinner, Sir Henry Anderson proposed the toast of the "Writers on Science," coupling with it the name of Dr. B. W. Richardson, who, in returning thanks, spoke of the advantages enjoyed by poet, theologian, historian and novelist, compared with those of the writer on science. After speaking of the embarrassment he experienced in having to respond to a toast so novel to him, that he doubted any one had ever heard it proposed at a public assembly, he said that while the speech of Sir Henry Anderson had caused to pass before his mind a broken dream of the men classed as writers on science, the duty of replying had raised the question—

"Who are the writers on science? Are they as well known as other great writers? They are not. They are less fortunate, and, therefore, the more worthy of the exceptional honour you would bestow on them. Excuse me a moment or two while I indicate the peculiarities of the position of the writer on science. He is a man communicating to the world that which is, by comparison, new to the world. The poet can cast back for his models to a time when the Greeks had not so much as the figment of an alphabet. The theologian may go back for his lesson to the earliest manifestations of the life of intellect on the planet. The historian finds subject and matter ready for his hand from the oldest and remotest, as well as the newest, writings and traditions of races and peoples. The story-teller is embarrassed with the richness of the past, and troubled by the greed of his admirers for more of his work. These all, indeed, are but the continuing interpreters of things, events, thoughts, which every man who claims to read claims also to understand. The writer of science has none of these advantages; he is but newly born into an old world of thought, and is not simply telling of new wonders, but is often himself learning at the same time as he is instructing an audience unlearned in his knowledge. Thus he comes slowly into the recognized brotherhood of men of letters; at the best he speaks to but a small audience, amuses rarely, excites, sometimes without intention, hopes that are delusive, and requires always, in order that he may be fairly understood, a degree of patience it is vain to expect from the multitude. To these difficulties others are added belonging to the work he accomplishes. The most original writers on science are destroyed constantly by the magnitude and overpowering character of the work they have written, and by the practical results that spring from the work. In other literature the book produced lives as the book, and the learner from it, age after age, must go back to the fountain-head to drink and drink; in science-literature the book sinks into the fact it proclaims, and the fact remains the exclusive master of the field. A striking example of this flashes across my mind at the present moment. Every reading man and woman knows that in the reign of Queen Elizabeth the book of Shakespeare's plays had its origin, and nearly every one who has read that book (and who has not?) remembers the curious saying in it, 'I'll put a girdle round the world in forty minutes.' But how many are there who have read another great book of that same reign, entitled 'De Magnete,' or are aware that at the time when Shakespeare was writing his now familiar phrases, the author of the book on the magnet, the Queen's Physician, one William Gilbert, when his daily toils of waiting upon the sick were over, was working with his smith in the laboratory at his furnace, needle and compass, was writing up for the first time the word 'Electricity,' and was actually forging the beginnings of the very instruments that now, in less than forty seconds, put the girdle round the globe? Again, writers on science are lost sometimes in the blaze of their own success. They raise wonder by what they do, and fall beneath it. All knowledge newly born is miracle, but by-and-by, as the knowledge becomes familiar, the miracle ceases. In this way advances in science become part of our lives, while the men who write them down cease to us. When the Leyden jar was first described, Europe was mentally as well as physically convulsed with the thing; now a Leyden jar is a common object—we all know it; but how few know of Mr. Cuneus, who first described this instrument of science! The whole civilized world is cognizant in this day that communication from one part of the world to the other, by telegraph, is almost child's play; but how many have seen or heard of Mr. Cavallo's original essay on 'Electricity' as a means of communicating intelligence to places distant from each other? There is nothing more commonplace in our day than to know that a living human being can be placed in gentle sleep, and while in blissful oblivion, can have performed on him what were once the tortures of the surgeon's art; but how few have heard or seen Sir Humphry Davy's paper announcing to mankind this grand beneficence! These are some of the difficulties of writers on science.

"And yet there is another I must name, be it ever so lightly. I refer to the desperate struggles of the man of science who has nothing but science to carry him on in life. None but such as are placed as I am, practising as physicians in this metropolis of the world, and admitted at the same time, as men of science, into some knowledge of the subject upon which I now speak, can form a conception of the almost hopelessness of the position of the pure scholar in science. On this I say no more. I would awaken, but not weary, your sympathy. Ladies and gentlemen, in speaking of writers on science, you will say, perhaps, I have spoken in sadness. It is not so; much of the difficulty these writers have had to bear I recognize with admiration as their truest glory, and I see that hope for better worldly prospects is near. A profession of science is, no doubt, organizing. The world is at last asking men of science to employ themselves in teaching the world; and the teachers, bending to the labour, are, in their turn, willing to suspect that they are but as children, or at best, youths in the race after knowledge. This is most hopeful; and it is hopeful also to find that men like you, my Lord Bishop, who claim to be the conservators of a knowledge that was matured when science was unborn, are listening now to our scholars with an attentive ear, and are beginning to accept that the Lord of Nature, whether He reveal Himself to the ancient lawgiver in the burning bush that was not consumed, or to the modern astronomer in the burning glory of the omnipotent sun, is one and the same Lord. Thus there is hope, I may say certainty, in the future for the literature of science; for its poetry, its parables, its facts, nay, even for its religion. I might bring proof of this belief from many sides. I am content to find it here; that in an assembly so distinguished writers on science should have been so enthusiastically remembered, and my poor attempt at reply so generously received. For both kindnesses from my heart I thank you."

THE DISTRESSED CHEMISTS IN FRANCE.

It will be in the recollection of our readers that an application was made to the Council at their last meeting for assistance to the distressed chemists in Paris and the neighbourhood, and that the Council decided that they had not the power to apply the funds of the Society for such a purpose.

A subscription was, however, immediately started, and the following list has been handed to us for publication. We understand that contributions may be sent to Mr. Elias Bremridge, 17, Bloomsbury Square.

	£.	s.	d.

The Tonquin or Tonga bean (*Dipteryx odorata*, Willd.) is well-known for its agreeable hay-like fragrance. The only uses made of these beans are, we believe, for scenting snuff and as an ingredient in perfumed sachets, for which purposes they are imported into this country. It is not a little remarkable that a closely-allied species, *D. Eboënsis*, the Eboe-nut tree of the Mosquito shore,—which has a fruit and seed so nearly resembling the Tonquin as to be scarcely distinguishable,—has no fragrance whatever, but contains a large quantity of fatty oil, which is expressed by the natives and used as a hair oil. The "Mexican Balm" once so much advertised for promoting the growth of the hair, is said to be made from this oil.

In a Report to the Department of Agriculture at New York, Dr. C. C. Parry states the general result of his inquiries, made during a recent visit to Jamaica, in regard to the cultivation of the Cinchona in that island, and the possibility of its introduction into the United States. He says that the peculiar conditions of soil and climate required for the growth of the best varieties of the cinchona plant cannot be found within the limits of the United States, where no suitable elevations possessing an equable moist, cool climate, free from frost, can be met with. He thinks that the island of San Domingo, situated within the tropics, and traversed by extensive mountain ranges, attaining elevations of over 6000 feet above the sea, presents a larger extent of country specially adapted to the growth of cinchonas than any other insular region in the western hemisphere, and that the material for stocking successful plantations in that island might be conveniently and economically obtained from Jamaica.

The official *Preussische Staatsanzeiger* states that Mr. E. Gressler, of Halle, the well-known pharmacist and manufacturer of mineral-water apparatus, has placed at the disposal of the Government one of his apparatus to the value of 150 thalers, to be given as a present to a pharmacist who has distinguished himself either in the execution of his duties as field apothecary, or in open field against the enemy.

* For the distressed chemists of France *generally*.

Transactions of the Pharmaceutical Society.

EXAMINATION IN EDINBURGH.

July 18th, 1871.

Present—Messrs. Ainslie, Aitken, Brown, Gilmour, Kemp and Young.

FIRST, OR PRELIMINARY EXAMINATION.

Twelve candidates were examined; the following nine passed, and were declared qualified for registration as

APPRENTICES OR STUDENTS.

Macdonald, Alexander........Edinburgh.
Dott, David Brown..........Edinburgh.
Equal. { Campbell, Colin............Dumbarton.
Grant, Donald..............Elgin.
Strang, David James........Perth. }
Equal. { Graham, Alexander..........Leith.
Maclean, Alexander Edward..Edinburgh. }
Equal. { Couper, Charles James......Edinburgh.
Mortimer, Robert............Edinburgh. }

The above names are arranged in order of merit.

The under-mentioned submitted evidence of having passed certain examinations, which was accepted in lieu of the Preliminary Examination:—

Wilson, David Morgan Weir..Edinburgh.

MINOR EXAMINATION.

The following seven candidates were examined, and were declared qualified for registration as

CHEMISTS AND DRUGGISTS.

Woods, Joseph Henry........Warrington.
Bayne, Charles..............Edinburgh.
Meldrum, David.............Edinburgh.
Macmillan, James Laker......Glasgow.
Gardner, William............Inverkeithing.
Equal. { Alexander, Hugh Dalrymple..Edinburgh.
Wilson, David Morgan Weir..Edinburgh. }

The above names are arranged in order of merit.

MODIFIED EXAMINATION.

The three following candidates were examined, and declared qualified for registration as

CHEMISTS AND DRUGGISTS.

Dickson, William............Edinburgh.
Pasco, John................Manchester.
Stanway, Edward Thomas....Wolverhampton.

Provincial Transactions.

LEICESTER CHEMISTS' AND APPRENTICES' ASSOCIATION.

The Half-yearly Meeting of the above Association was held at the Rooms, Halford Street, on Friday, August 4th; the President (Mr. W. B. Clarke) in the chair. Some preliminary business having been transacted, the Honorary Secretary, Mr. T. Wright, read the following report:—

"During the session, one member has passed the Minor Examination with honours, and two have succeeded in the Preliminary. During the half-year five papers have been read upon subjects of great interest to pharmacists; the Chemistry, Botany, Materia Medica, and Latin Classes have been regularly attended, the average number present at each class being eight. W. S. Grigsby, Esq., has very kindly taken the management of a class for the preparation of students for the Preliminary Examination; and as this gentleman's services are entirely voluntary, the Committee take this opportunity of tendering him their grateful thanks, especially as the rapid advance of the apprentices of the Association proves that the talents of Mr. Grigsby, coupled with his admirable method of teaching, have not been thrown away.

"The financial affairs of the Association are not in so prosperous a condition as usual, owing to the great expense of the very convenient rooms in Halford Street; but the Committee trust, with the sustained help of the principals, to meet the difficulty. Finally, the Committee believe they have reason to congratulate the members upon the great success the Association has had, and is still increasingly having, in achieving the purposes for which it was formed."

The following officers were then elected by ballot:—*President:* Mr. W. E. Hill (A.P.S.). *Vice-President:* Mr. T. Wright (A.P.S.). *Treasurer:* Mr. W. B. Clarke (P.C.). *Hon. Secretary:* Mr. W. B. Blunt (A.P.S.). *Committee:* Mr. E. H. Butler (A.P.S.); Mr. W. Thirlby (A.P.S.); Mr. S. H. Cadoux.

The balance sheet showed a balance due to Treasurer of £3. 17*s.* 4½*d.*, which by a repayment from the Pharmaceutical Society of £4. 18*s.* 8*d.* expended in books, would be converted into a balance in hand of £1. 1*s.* 3½*d.*

A programme of lectures, etc., extending from August 10, 1871, to February 1, 1872, has been issued.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 132.)

Mr. A. H. Mason, F.C.S., read a report on "The Chloral of Trade."

The President said that, before asking for any discussion on this paper,—and he knew there were many who would take part in it,—there was another by Mr. M. W. Pattison Muir, F.C.S., which he thought might be also read.

At this point Dr. Edwards entered the room, and was received with loud applause.

The President said he wished to express the satisfaction he had of seeing Dr. Edwards present.

Dr. Edwards said it gave him pleasure to be among so many friends; and, in speaking of the Pharmaceutical Society of Quebec, said it had some privileges which he might have an opportunity of referring to by-and-by.

Mr. Pattison Muir's paper on "An Examination of Samples of Commercial Chloral Hydrate" was then read by Dr. Attfield.

The author said that the experiments had been undertaken, not with any intention of adding new facts or new reasonings to the science of pharmaceutical chemistry, but rather with the view of showing whether or not the chloral hydrate in common use among druggists and pharmacists is of fair average purity. He had endeavoured to answer, for each sample examined, the following questions:—

(1.) Does the sample yield, on treatment with a caustic alkali, such a percentage of chloroform as might reasonably be expected.

(2.) Does the sample contain any, or any appreciable, amount of chloral alcoholate?

And lastly, is the chloral hydrate now generally sold by druggists of fair average quality and purity?

The results at which he had arrived were,—

(1.) Generally the samples were of a fair average quality.

(2.) None of them, so far as could be inferred from the experiments, contained chloral alcoholate.

(3.) The purest was that sold in small transparent pieces, nearly dry to the touch, and not having a very strong pungent odour.

(4.) The various samples varied in the amount of chloroform yielded,—chiefly, it appeared, on account of the time each had stood in the shop.

Generally, the experiments showed that the chloral hydrate at present sold by pharmaceutical chemists is of a fair degree of purity.

The PRESIDENT said he would be glad to hear any one who would give some results of his experiments. He saw Dr. Paul, Mr. Wood, Mr. Williams and others present who, he had no doubt, would take part in the discussion.

Dr. PAUL said he had nothing further to say than that both the papers seemed to confirm the general result arrived at by several experimenters some time ago, viz. that the hydrate of chloral of commerce was so far a pure article that the amount of impurity varied within the narrow limits of about 5 per cent.; and it was only in a few cases that it came up to as much as 5 per cent. In those cases where the amount of hydrate of chloral in the commercial article was 1, or 2, or 3, or 5 per cent. less than if the article were absolutely pure hydrate of chloral, the impurity was in most cases water, due to the hygroscopic nature of the substance. In the specimens he himself examined there was only one case of alcoholate met with, and that was not a bought sample, but one obtained as a specimen from a house in the City reported to have been selling it. Another impurity that was observed in one or two cases was a flocculent deposit that was formed when the ammonia-test was applied. That deposit obscured the test, and one was not able to tell how much chloroform was produced, because the deposit collected between the chloroform and the watery liquid rendered indistinct the line of separation between the two substances.

Mr. WOOD said that in the remarks he was about to make he would probably run somewhat counter to the general current of opinion, but he must protest against attaching too much importance to the chloroform-test. It occurred to him that it was leading them rather astray, and likely to do more harm than good. No doubt it was very valuable, and served a useful purpose when it was suggested by Mr. Williams, but what they required at the present time, he believed, was a means of recognizing that they had chloral hydrate, and no other chlorine substance or impurity which might be formed during the process of manufacture. The chloroform-test was not required, as it appeared to him, because it was not a sufficient means of ascertaining the purity in these respects, and because the presence or absence of a little more or less water in a chloral hydrate was a matter of slight importance to them, provided that they had pure chloral and no other substance. It could merely affect the commercial and not the medicinal value. He believed it was the general experience, as stated by Dr. Paul and others, that what caused the principal variations in the chloroform results was the presence of rather more or less water in the sample they were examining. In the manufacture of chloral it did appear probable that there were produced certain other chlorinated substances, and that these might remain associated with the chloral in greater or less proportion; and those substances were likely to have considerable influence on the medicinal properties of the article. There was a very great temptation to every manufacturer to stop the action of the chlorine upon the alcohol, as soon as it would yield a crystallizable article that was saleable; but still at that time it might retain more or less, and sometimes a considerable portion, of those other products that had been first formed, and from which the chloral had been derived. An ethereal oily liquid, of high boiling-point, described by Liebig, Dumas and others as the original chloric ether, was the body first formed by the action of chlorine on alcohol. It was that body which ultimately yielded chloral by the further action of chlorine, and it was that which would be likely to influence its medicinal efficacy. Moreover, alcohol of commerce was by no means pure, it contained considerable quantities of fusil oil and other products; and if in the manufacture of chloral such spirit had been used, they would have the products of the action of chlorine on those other substances which were impurities in the alcohol. German spirit was known to contain appreciable quantities of aldehyd; and Dr. Hofmann had recently shown that aldehyd yielded by the action of chlorine a crystalline body resembling chloral, but having an entirely different composition. As far as his experience went, the chloroform-test failed to be of much use in indicating the presence or absence of such substitution products. Many of these substances did give an oily liquid on treatment with an alkali. It might or might not be chloroform. It might consist of that alone, or it might contain other liquids. They never applied any further means of recognizing the purity of the chloroform layer. They had no means of examining it. It appeared to him, therefore, that the test was apt to mislead them; for if they got a good result in point of quantity they thought the sample good. But what they really required was the means of testing chloral, so as to recognize the presence of other chlorine products. He was inclined to regard the boiling-point as a more valuable test to apply. Unfortunately it seemed impossible to distil hydrate of chloral to absolute dryness without increasing the boiling-point. He thought they required some test which would show the presence of other substances than chloral, rather than being particular as to whether they got 1 or 2 per cent. of water in excess.

Dr. PAUL said he wished to express the satisfaction with which he had heard Mr. Wood's remarks. He thought he had taken the true chemist's point of view, and had raised a question as to the purity of hydrate of chloral in a far more important manner than had yet been done. Looking to the materials used for the manufacture of hydrate of chloral, there was, he thought, no doubt that there might be other chlorine compounds in the chloral hydrate of commerce. He was sure that everybody would agree with him in hoping that before the Conference met next year Mr. Wood would exercise the ability and opportunities he possessed of carrying out an inquiry in such a way that he could place before them some positive evidence on the matter. He did not know any one who could do it so well.

Mr. WILLIAMS said he agreed with Mr. Wood as to the importance of discovering other chlorine compounds in chloral. He explained some experiments he had made in distillation, and said he thought the redistilled chloral much sweeter and nicer in flavour than the chloral from which it was prepared. It was all the purer, and warranted the expense of distillation.

Mr. HANBURY said he did not understand the author of the first paper to say, whether the samples he examined had been obtained from manufacturers who were previously informed that they were for analysis, or in the ordinary way of trade. That was one point he thought they should know.

Mr. UMNEY said the author had proved that chloral hydrate had been manufactured in large quantities in this country. He thought they were entitled to know where it was manufactured, as they were told that there was only one place where it was produced. Perhaps Mr. Mason could enlighten them on the subject.

Mr. MASON said he applied to manufacturers for chloral hydrate and they sent it to him. One firm refused to entrust him with a sample of their manufacture.

Mr. UMNEY said he knew one house that had tried to manufacture it, but the product was mixed with alcoholate. Perhaps Mr. Wood could give some information on the subject.

Mr. WOOD said he thought it was a misfortune to introduce manufacturers' names into such matters; but as the question had been asked, he might state that he knew of a firm in London, the one named by Mr. Mason as sending him samples, that made large quantities of hydrate chloral, and he believed it was in a considerable state of purity.

Mr. Kerr (Dundee) asked if he could be informed whether there was any general test of smell by which a good sample of hydrate of chloral could be distinguished from a bad one. On one occasion he received a sample which had not the sweet smell of chloral, but an acrid smell. He asked the opinion of a firm on the subject, and they told him that it was good, and that the smell varied. When the stopper of a bottle was taken out it left the chloral different from what it was when quite close. It would be useful to dispensing chemists to know whether there was any test such as he had indicated.

Mr. Atkins said he also wished to put a question. He had not yet quite learned from the debate whether the cake or the crystalline form was to be considered the best and purest specimen for dispensing.

Mr. Mason said he had already answered both questions.

Dr. Attfield said Mr. Muir seemed to have come to the conclusion that the crystalline was the best.

Mr. Robins (London) said that a gentleman of his acquaintance had got some pounds of the crystalline substance, but after trying it he gave it up, and returned to the use of the cake. He said that in many cases he did not find the action so good. He (Mr. Robins) thought it would be well to know if similar results were found in other cases.

The President, in regard to Mr. Kerr's question, said that probably the sense of smell would not be sufficient as a substitute for a chemical test. In the case of pure chloral the pungent smell disappeared, by constant opening of the bottle. The discussion seemed to be satisfactory as to the state of chloral as a manufactured product. In his own experience at Bristol he had found it to give him satisfaction.

Brief Remarks on the Bark of Rhamnus Frangula, or Black Alder Tree, a Shrub of the North of Europe (Pentandria Monogynia).

BY H. C. BAILDON, EDINBURGH.

Some time since a gentleman from Holland applied to me to prepare for him a decoction of the *Rhamnus Frangula* bark. The bark he brought with him, having previously found that he could not obtain it in this country. He spoke most enthusiastically of its good properties as a gentle cathartic, which had proved very beneficial to himself, and which was much used and esteemed by the medical profession in Holland. He kindly offered to procure for me a small quantity of the bark. To my surprise, I shortly afterwards received a bale containing nearly a quarter of a cwt., accompanied by the following letter. He writes, "I hope you will find it giving as much benefit generally as I have derived from it personally. The preparation of my Dutch physician was 3 or 4 drams of bark to a pint of water boiled down to half a pint. Two or three tablespoonfuls occasionally night and morning, as an aperient. Than this nothing can be more simple or less injurious, and it does not require increase of dose, but the contrary."

I am aware that this drug is not altogether unknown in this country, though I believe rarely or never used. In the 2nd volume of the first series of the Pharmaceutical Journal, page 721, I find a letter signed George Mennie, Plymouth, speaking very favourably of it as a purgative and alterative, and again in the 9th volume, page 537, there is an analysis by M. Benswanger.

I have repeatedly taken the decoction myself, and find the taste not unpleasant, with a slight prussic acid flavour, of which the analysis shows traces. It operates gently as an aperient, without griping, in doses of 2 or 3 tablespoonfuls. It appears to me to possess properties which should in many cases render it a valuable substitute for senna,—which is often found drastic in its effects, and is nauseous to take,—and to be especially suitable for children.

In Holland it must be very plentiful, as it was charged me only at the rate of about 10*d.* per lb., including cost of carriage. A specimen of the bark and decoction is now upon the table.*

The Conference then adjourned from half-past twelve to two o'clock.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

On Thursday, August 3, the business of the sections commenced. The meetings were held in the various class-rooms of the University, the time saved to visitors by the contiguity of the places of meeting being very considerable.

In Section A. (Mathematical and Physical Science), Professor P. G. Tait, the President, delivered an address, in which he claimed that the grand test of the science, and the proof of its being a reality, and not a mere invention of new terms and squabbling as to what they shall mean, is that it is ever advancing. There is no coming back at the end of a century or so into the old positions, and fighting the selfsame battle over again under slightly different banners. The sad fate of Newton's successors ought ever to be a warning to us. Trusting to what he had done, they allowed mathematical science to die out in this country, at least as compared with its immense progress in Germany and France. If the successors of Davy and Faraday pause to ponder even on their achievements, we shall soon be again in the same state of ignominious inferiority. Even as it is, though we have among us many names as justly great as any that our rivals can produce, we have also (even in our educated classes) such an immense amount of ignorance, and consequent credulity, that it seems matter for surprise that true science is able to exist. Spiritualists, circle squarers, perpetual motionists, believers that the earth is flat and that the moon has no rotation, swarm about us. This is characteristic of all inferior races, but it is consolatory to remember that, in spite of it, they soon become extinct. Your quack has his little day, and disappears, except to the antiquary. But in science nothing of value can ever be lost; it is certain to become the stepping-stone on the way to further truth. Still, when our stepping-stones are laid, we should not wait till others employ them.

Professor James Thomson read a paper entitled "Speculations on the Continuity of the Fluid State of Matter." The author referred to the discovery of Dr. Andrews, that there is gradual transition between the ordinary liquid and the ordinary gaseous states of the same matter, by courses passing through temperatures and pressures above those at which boiling can take place, and showed that there is probably also a theoretical continuity, having a real and true significance, directly across temperatures and pressures of boiling-points. He also drew the attention of the section to the existence for each of the various substances (water or carbonic acid, for instance) of a remarkable point of pressure and temperature, at which alone the substance can exist in three states, solid, liquid and gaseous, together in contact with one another. This point of pressure and temperature he designated the triple point.

---

* We are requested to state that Mr. Baildon will, with pleasure, supply members of the Conference with specimens of this bark, to afford them the opportunity of testing its merits.—Ed. Pharm. Journ.

Dr. Carpenter read a paper on the "Thermo-Dynamics of the General Oceanic Circulation," which gave rise to considerable discussion, in which Sir William Thomson, Professor Stokes, and Professor G. C. Foster took part.

Section B.—Chemical Science.

This section met under the presidency of Dr. Andrews, F.R.S., who, in his address, spoke of the difficulty of giving a historical review of the science, more particularly in organic chemistry, where it was impossible to grapple with the large number of valuable works which even a few months produce. We give an abstract of some of the principal topics referred to. In commencing, he remarked that amidst the vicissitudes to which scientific theories are liable, it was scarcely to be expected that the discarded theory of phlogiston should be resuscitated in our day, and connected with one of the most important generalizations of modern science. The phlogistic theory, elaborated nearly two hundred years ago by Beecher and Stahl, was not, it now appears, wholly founded on error; on the contrary, it was an imperfect anticipation of the great principle of energy, which plays so important a part in physical and chemical changes. The disciple of phlogiston, ignorant of the whole history of chemical combination, connected, it is true, his phlogiston with one only of the combining bodies, instead of recognizing that it is eliminated by the union of all.

Dr. Andrews referred to a recent attempt to ignore the labours of Black and his contemporaries, and to attribute the foundation of modern chemistry to Lavoisier alone; and said that, through the kindness of Dr. Black's representatives, he had been permitted to examine his correspondence, which has been carefully preserved, and had been so fortunate as to find in it three original letters from Lavoisier to Dr. Black. They were written in 1789 and 1790, and they appear to comprise the whole of the correspondence on the part of Lavoisier which passed between those distinguished men. He would crave permission to have them printed as an appendix to his address. Lavoisier, it will be seen, addresses Black as one whom he was accustomed to regard as his master, and whose discoveries had produced important revolutions in science. It may indeed be said with truth that Lavoisier completed the foundation on which the grand structure of modern chemistry has since arisen; but Black, Priestley, Scheele and Cavendish were before Lavoisier, and their claims to a share in the great work are not inferior to those of the illustrious French chemist.

Among the questions of general chemistry, few have of late attracted more attention than the relations which subsist between the chemical composition and refractive power of bodies for light. About twenty years ago Delffs remarked that the refractive indices of the compound ethers increase with the atomic weight, and that isomeric ethers have the same refractive indices. The later researches of Gladstone and of Landolt have, on the whole, confirmed these observations, and have shown that the specific refractive power depends chiefly on the atomic composition of the body, and is little influenced by the mode of grouping of the atoms. These inquiries have gone further, and have led to the discovery of the refraction equivalents of the atoms. By comparing the refractive power of compound bodies differing from one another by one or more atoms of the same element, Landolt succeeded in obtaining numbers which express the refraction equivalents of carbon, hydrogen and oxygen, and corresponding numbers have been obtained for other elements by Gladstone and Haagen. The whole subject has been recently discussed and enriched with many new observations in an able memoir by Gladstone. As might be expected in so novel and recondite a subject, some anomalies occur which are difficult to explain. Thus, hydrogen appears in different classes of compounds with at least two refraction equivalents, one three times as great as the other; and the refraction equivalents of the aromatic compounds and their derivations as given by observation are, in general, higher than the calculated numbers.

In a "Report on the Heat of Combination" which was made to this Association in 1849, the existence of a group of isothermal bases was pointed out. "As some of the bases,—potash, soda, baryta, strontia,—" it was remarked, "form what we may perhaps designate an isothermal group, such bases will develope the same, or nearly the same heat, in combining with an acid, and no heat will be disengaged during their mutual displacements." The latest experiments of Thomson have given a remarkable extension to this group of isothermal bases. He finds that the hydrates of lithium, thallium, calcium and magnesium produce, when all corrections are made, the same amount of heat on being neutralized by sulphuric acid as the four bases before mentioned. The hydrate of tetramethylammonium belongs to the same class of bases. Ethylamin, on the other hand, agrees with ammonia, which, as has long been known, gives out less heat in combining with the acids than potash or soda. An investigation of the amount of heat evolved in the combustion of coal of different kinds has been made by Scheurer-Kestner and Meusnier, accompanied by analyses of the coal. Coal rich in carbon and hydrogen disengages more heat in burning than coal in which those elements are partially replaced by oxygen. After deducting the cinders, the heat produced by the combustion of 1 gramme of coal varied from 8215 to 9622 units.

Tyndall has given an account of his experiments on the action of a beam of strong light on certain vapours. He finds that there is a marked difference in the absorbing power of different vapour for the actinic rays. Thus, the nitrate of amyl in the state of vapour absorbs rapidly the rays of light competent to decompose it, while iodide of allyl in the same state allows them freely to pass. Morren has continued these experiments in the south of France, and, among other results, he finds that sulphurous acid is decomposed by the solar beam.

Roscoe has prosecuted the photo-chemical investigations which Bunsen and he began some years ago. For altitudes above 10 degrees the relation between the sun's altitude and the chemical intensity of light is represented by a straight line. Till the sun has reached an altitude of 20 degrees, the chemical action produced by diffused daylight exceeds that of the direct sunlight. The two actions are then balanced, and at higher elevations the direct sunlight is superior to the diffused light. The supposed inferiority of the chemical action of light under a tropical sun to its action in higher latitudes proves to be a mistake. According to Roscoe and Thorpe, the chemical intensity of light at Pará under the equator, in the month of April, is more than three times greater than at Kew in the month of August.

Hunter has given a great extension to the earlier experiments of Saussure on the absorptive power of charcoal for gases. Cocoa-nut charcoal, according to Hunter's experiments, exceeds all other varieties of wood charcoal in absorptive power, taking up at ordinary pressures 170 volumes of ammonia and 69 of carbonic acid. Methylic alcohol is more largely absorbed than any other vapour at temperatures from 90° to 127°; but at 159° the absorption of ordinary alcohol exceeds it. Cocoa-nut charcoal absorbs 44 times its volume of the vapour of water at 127°. The absorptive power is increased by pressure.

Last year two new processes for improving the manufacture of chlorine attracted the attention of the section; one of these has already proved to be a success, and I am glad to be able to state that Mr. Deacon has recently overcome certain difficulties in his method, and has obtained a complete absorption of the chlorine. May we hope to see oxygen prepared by a cheap and continuous process from atmospheric air? With baryta the problem can be solved very perfectly, if not economically. Another process is that of Tessier de Mothay, in which the manganate of potassium is decomposed by a current of superheated steam, and afterwards revived by being heated in a current of air. A company has lately been formed in New York to apply this process to the production of a brilliant house-light. A compound argand burner is used, having a double row of apertures; the inner row is supplied with oxygen, the outer with coal-gas or other combustible. The applications of pure oxygen, if it could be produced cheaply, would be very numerous, and few discoveries would more amply reward the inventor. Among other uses, it might be applied to the production of ozone free from nitric acid by the action of the electrical discharge, and to the introduction of that singular body in an efficient form into the arts as a bleaching and oxidizing agent. Tessier de Mothay has also proposed to prepare hydrogen gas on the large scale by heating hydrate of lime with anthracite.

The researches of Roscoe have made us acquainted, for the first time, with metallic vanadium. Berzelius obtained brilliant scales which he supposed to be the metal, by heating an oxychloride in ammonia, but they have proved to be a nitride. Roscoe prepared the metal by reducing its chloride in a current of hydrogen, as a light grey powder, with a metallic lustre under the microscope. It has a remarkable affinity both for nitrogen and silicon. Like phosphorus, it is a pentad, and the vanadates correspond in composition to the phosphates, but differ in the order of stability at ordinary temperatures, the soluble tribasic salts being less stable than the tetrabasic compounds.

In organic chemistry the labours of chemists have been of late largely directed to a group of hydrocarbons which were first discovered among the products of the destructive distillation of coal or oil. The central body round which these researches have chiefly turned is benzol, whose discovery will always be associated with the name of Faraday. With this body naphthaline and anthracene form a series, whose members differ by C_4H_2, and their boiling-points by about 140°. The recent researches of Liebermann have proved, as was before suspected, that chrysene is a fourth member of the same series. I may add that ethylene, which boils at about 70°, corresponds in composition and boiling-point to a lower member of the same series. Kekulé propounded some time ago with great clearness the question as to whether the six atoms of hydrogen in benzol are equivalent, or on the contrary play dissimilar parts. According to the first hypothesis, there can be only one modification of the mono- and penta-derivatives of benzol; while three modifications of the bi-, tri-, and tetra-derivatives are possible. On the second hypothesis, two modifications of the mono-derivatives are possible, and in general a much larger number of isomeric compounds than on the first hypothesis. Such is the problem which has of late occupied the attention of some of the ablest chemists of Germany, and has led to a large number of new and important investigations. The aromatic hydrocarbons, toluol, xylol, etc., which differ from one another by CH_2, have been shown by Fittig to be methyl derivatives of benzol. According to the first of the two hypotheses to which I have referred, only one benzol and one methyl benzol (toluol) are possible, and accordingly no isomeric modifications of these bodies have been discovered. But the three following members of the series ought each to be capable of existing in three distinct isomeric forms. The researches of Fittig had already established the existence of two isomeric compounds having the formula C_8H_{10}—methyl toluol obtained synthetically from toluol, and isoxylol prepared by the removal of an atom of methyl from the mesytelene of Kane. The same chemist has since obtained the third modification, orthoxylol, by the decomposition of paraxylylic acid. These three isomeric hydrocarbons may be readily distinguished from one another by the marked difference in the properties of their trinitro-compounds, and also by their different behaviour with oxidizing agents.

Baeyer has prepared artificially picoline, a base isomeric with aniline, and discovered by Anderson in his very able researches on the pyridine series. Of the two methods described by Baeyer, one is founded on an experiment of Simpson, in which a new base was obtained by heating tribromallyl with an alcoholic solution of ammonia. By pushing further the action of the heat, Baeyer succeeded in expelling the whole of the bromine from Simpson's base in the form of hydrobromic acid, and in obtaining picoline. The same chemist has also prepared artificially collodine, another base of the pyridine series. To this list of remarkable synthetical discoveries, another of the highest interest has lately been added by Schiff—the preparation of artificial coniine. He obtained it by the action of ammonia on butyric aldehyde (C_4H_8O).

Valuable papers on alizarine have been published by Perkin and Schunck. The latter has described a new acid—the anthraflavic—which is formed in the artificial preparation of alizarine. Madder contains another colouring principle, purpurine, which, like alizarine, yields anthracene when acted on by reducing agents, and has also been prepared artificially. These colouring principles may be distinguished from one another, as Stokes has shown, by their absorption bands; and Perkin has lately confirmed by this optical test the interesting observation of Schunck, that finished madder prints contain nothing but pure alizarine in combination with the mordant employed.

Hofmann has achieved another triumph in a department of chemistry which he has made peculiarly his own. In 1857 he showed that alcohol bases, analogous to those derived from ammonia, could be obtained by replacement from phosphuretted hydrogen; but he failed in his attempts to prepare the two lower derivatives. These missing links he has now supplied, and has thus established a complete parallelism between the derivatives of ammonia and of phosphuretted hydrogen. The same able chemist has lately described the aromatic cyanates, of which one only, the phenylic cyanate (CO, C_6H_5, N), was previously known, having been discovered about twenty years ago by Hofmann himself. He now prepares this compound by the action of phosphoric anhydride on phenylurethane, and by a similar method he has obtained the tolylic, xylylic, and naphthylic cyanates.

Stenhouse had observed many years ago that when aniline is added to furfurol, the mixture becomes rose-red, and communicates a fugitive red stain to the skin, and also to linen and silk. He has lately resumed the investigation of this subject, and has obtained two new bases, furfuraniline and furfurtoluidine, which, like rosaniline, form beautifully coloured salts, although the bases themselves are nearly colourless or of a pale brown colour. The furfuraniline hydrochlorate ($C_{17}H_{19}O_2N_2Cl$) is prepared by adding furfurol to an alcoholic solution of aniline hydrochlorate containing an excess of aniline. We have also from Stenhouse a new contribution to the history of orcin, in continuation of his former masterly researches on that body. He has prepared the trinitroorcin ($C_7H_5(NO_2)_3O_2$), a powerful acid having many points of resemblance to picric acid. In connection with another research of Stenhouse, made many years ago, it is interesting to find his formula for esexanthron, which was also that of Erdmann, confirmed by the recent experiments of Baeyer.

The interesting work of Dewar on the oxidation of picoline must not be passed over without notice. By the action of the permanganate of potassium on that body, he has obtained a new acid which bears the same relation to pyridine that phthalic acid does to benzol. Thorpe and Young have published a preliminary notice of some results of great promise, which they have obtained by exposing paraffin to a high temperature in closed vessels. By this treatment it is almost completely resolved into liquid hydrocarbons, whose boiling-points range from 18° C. to 300° C.; those boiling under 100° C. have been examined, and consist chiefly of olefines. In connection with this subject, it may be interesting to recall the experiments of Pelouze and Cahours on the Pennsylvanian oils, which proved to be a mixture of carbohydrogens belonging to the marsh-gas series.

An exposition of Berthelot's method of transforming an organic compound into a hydrocarbon containing a maximum of hydrogen, has appeared in a connected form. The organic body is heated in a sealed tube, with a large excess of a strong solution of hydriodic acid, to the temperature of 250°. The pressure in these experiments Berthelot estimated at 100 atmospheres. He has thus prepared ethyl hydride (C_2H_6) from alcohol, aldehyd, etc.; hexyl hydride (C_6H_{14}) from benzol. Berthelot has submitted both wood charcoal and coal to the reducing action of hydriodic acid, and, among other interesting results, he claims to have obtained in this way oil of petroleum.

By the action of chloride of zinc upon codeia, Matthiessen and Burnside have obtained apocodeia, which stands to codeia in the same relation as apomorphia to morphia, an atom of water being abstracted in its formation. Apocodeia is more stable than apomorphia, but the action of reagents upon the two bases is very similar. As regards their physiological action, the hydrochlorate of apocodeia is a mild emetic, while that of apomorphia is an emetic of great activity. Other bases have been obtained by Wright by the action of hydrobromic acid on codeia.

We are indebted to Crum-Brown and Fraser for an important work on the relation between chemical constitution and physiological action. It has long been known that the ferrocyanide of potassium does not act as a poison on the animal system, and Bunsen has shown that the kakodylic acid, an arsenical compound, is also inert. Crum-Brown and Fraser find that the methyl compounds of strychnia, brucia, and thebaia are much less active poisons than the alkaloids themselves, and the character of their physiological action is also different. The hypnotic action of sulphate of methyl-morphium is less than that of morphia. But a reverse result occurs in the case of atropia, whose methyl and ethyl derivatives are much more poisonous than the salts of atropia itself.

Before proceeding to the subject of fermentation, I may refer to Apjohn's chemico-optical method of separating cane sugar, inverted sugar, and grape sugar from one another when present in the same solution, by observing the rotative power of the syrup before and after inversion, and combining the indications of the saccharometer with the results of an analysis of the same syrup after inversion. Heisch's test for sewage in ordinary water is also deserving of notice. It consists in adding a few grains of pure sugar to the water, and exposing it freely to light for some hours, when the liquid will become turbid from the formation of a well-marked fungus, if sewage to the smallest amount be present. Frankland has made the important observation that the development of this fungus depends upon the presence of a phosphate, and that if this condition be secured, the fungus will appear even in the purest water.

The nature of fermentation, and in particular of the alcoholic fermentation, has been lately discussed by Liebig with consummate ability, and his elaborate memoir will well repay a careful perusal. Dr. Williamson has also given a most instructive account of the subject, particularly with reference to the researches of Pasteur, in his recent Cantor lectures. A brief statement of the present position of the question will therefore not be out of place here. It is now thirty-four years since Cagniard de la Tour and Schwann proved by independent observations that yeast globules are organized bodies capable of reproduction by gemmation; and also inferred as highly probable that the phenomena of fermentation are induced by the development or living action of these globules. These views, after having fallen into abeyance, were revived and extended a few years ago by Pasteur, whose able researches are familiar to every chemist. Pasteur, while acknowledging that he was ignorant of the nature of the chemical act, or of the intimate cause of the splitting up of sugar in the alcoholic fermentation, maintained that all fermentations, properly so called, are correlative with physiological phenomena. According to Liebig, the development and multiplication of the yeast-plant, or fungus, is dependent upon the presence and absorption of nutriment which becomes part of the living organism, while in the process of fermentation, an external action takes place upon the substance, and causes it to split up into products which cannot be made use of by the plant. The vital process and the chemical action, he asserts, are two phenomena which in the explanation must be kept separate from one another. The action of a ferment upon a fermentable body he compares to the action of heat upon organic molecules, both of which cause a movement in the internal arrangement of the atoms. The phenomena of fermentation Liebig refers now as formerly to a chemico-physical cause, the action, namely, which a substance in a state of molecular movement exercises upon another of highly complex constitution, whose elements are held together by a feeble affinity, and are, to some extent, in a state of tension or strain. Baeyer, who considers that in the alcoholic and lactic fermentations one part of the compound is reduced and another oxidized, adopts the view of Liebig that the molecules of sugar which undergo fermentation do not serve for the nourishment of the yeast-plant, but receive an impulse from it. All are, however, agreed that fermentation is arrested by the death of the plant, and even a tendency to the acetous fermentation in wine may be checked, as Pasteur has shown, by heating the wine to a temperature a little below boiling-point in the vessel in which it is afterwards to be kept.

Dr. Andrews concluded by saying that he could not refrain from bearing tribute to the great ability and indomitable perseverance which characterize the labourers in the great field of organic chemistry. It would scarcely be possible to conceive any work more intelligently undertaken or more conscientiously performed than theirs, yet much of it, from its abstruse character, receiving little sympathy or encouragement except from the band of devoted men who have made this subject the chief pursuit of their lives. They will, however, find their reward in the consciousness that they have not lived in vain, but have been engaged, and successfully engaged, in the noble enterprise of extending for the benefit of the human family the boundaries of scientific knowledge. Nor is there any real ground for discouragement: Faraday, Graham, Magnus, and Herschel, who have left their impress on this age, were all distinguished chemical as well as physical discoverers; and the relations of the sciences are becoming every day so intimate that the most special research leads often to results of wide and general interest.

BRITISH MEDICAL ASSOCIATION.

The British Medical Association commenced its thirty-ninth annual Meeting on Tuesday evening, August 8, at the Assembly Rooms, Plymouth.

Dr. Charlton, of Newcastle, took the chair, and, after the reception of an address of welcome from the Mayor and Corporation of Plymouth, proceeded to deliver his valedictory address. He said that, contrary to the expectations indulged in when he assumed office at the Newcastle meeting, the past year, instead of being one of great excitement among those interested in medical legislation, had been singularly barren of incident in regard to that which is the question of questions to the profession,—the all-important subject of medical reform. Twelve months ago a session of Parliament was hoped for in which this subject would have occupied no small portion of the time of our legislators, and preparations were made for the struggle. But the late session had been singularly unproductive in reference to general questions, and it was not matter for surprise that much attention had not been given to medical reform, a subject interesting to, and understood by, few beyond those who had a practical experience of its necessity. Questions of the most important character had been lost sight of in the din of contending armies across the Channel; but, in the meantime, leisure had been gained to analyse and improve upon the measures of reform proposed during the last twelve months. No measure of reform, they could boldly say, would ever be acceptable to the profession which did not embrace the two propositions, (1) the single portal by which all shall enter the profession, and (2) the radical and thorough reform of the Medical Council. He then introduced his successor, Dr. John Whipple, in whose favour he vacated the presidential chair.

The President-elect then proceeded to deliver his inaugural address, in which he deviated from the usual routine of discussing subjects of solely professional interest, and gave some interesting details in the history of Plymouth, the town in which they were assembled. He justified this course on the ground that professional experience abundantly testified that the mind could not bear too heavy a strain, or digest at once more than a fair proportion of substantial or stimulating diet. He wished to send them forth to the details and duties of their respective sections with their digestive faculties unwearied and their mental grasp unimpaired by any homœopathic treatment of his own. If it were true that the science of agriculture depended much upon a due application of the rotation of crops, it would not be far wrong to adopt a similar system to an analogous field—the human mind. In both cases the same condition of an ultimate return was a judicious appreciation of, and a proper deference to, those elements which might not inaptly be termed the surface and hidden depths of their respective systems. As with the field, so with the mind—a summer's fallow may have its advantages, and the crop of sprightly tares turn out no mean preparation for an ample yield of weightier cereals.

Dr. Sibson proposed, and Dr. Radclyffe Hall seconded, a vote of thanks to the retiring President, which was passed unanimously, and it was decided that Dr. Charlton should be enrolled among the permanent Vice-Presidents of the Society.

The Hastings Medal for 1870, which had been awarded to Dr. J. M. Fothergill for an essay on "Digitalis, its Mode of Action and its Use," was then presented to that gentleman, amid general cheering.

The Report was next read, from which we extract the following paragraphs:—

"At the Annual Meeting in 1870, there were on the list 4251 members, of whom 65 have died, 94 resigned, and 106 have been removed for non-payment of subscriptions. 411 new members have been elected this year. There are now 4403 on the books.

"The joint Committee on State Medicine will present a report—a report which deals closely with recommendations of the Royal Sanitary Commission, and the principles that should regulate the future sanitary administration of the kingdom, subjects full of interest both to the medical profession and the public; and which will doubtless occupy a prominent place in the deliberations of the meeting.

"The Therapeutical Committee have been at work during the year; they have performed a large number of experiments, and collected much valuable matter, but are not yet prepared to report the result of their labours. Your Council regret that Professor Hughes Bennett will not, in consequence of ill-health, be able to attend the Annual Meeting."

The Council being fully convinced that the amount of Association work done at, and the large sums of money passing through, the Journal office, imperatively demand that the duties of Secretary of the Association, and the management of the office, so interwoven with each other, should be performed by the same officer, who shall be directly responsible to the Committee of Council, recommend that in future the General Secretary shall reside in London, so that, in addition to the duties now required of him, he shall give personal attention to, and be responsible for, the management of the financial and business department of the Journal office.

After some discussion the Report was adopted.

On Wednesday the Association met in the Town Hall, Devonport, when an address of congratulation and welcome was presented from the mayor and corporation of that borough.

It was agreed that Birmingham be the place of meeting in 1872, and that Alfred Baker, Esq., be the President elect.

Mr. Watkin Williams was appointed to act as General Secretary till the end of the year, and a Committee was appointed to define the duties of the General Secretary, and to take steps for the appointment of, on the next annual meeting.

Dr. George Johnson then delivered the Address in Medicine. He referred to the great interest which was excited when, about fourteen years ago, the late Sir John Forbes published his book on 'Nature and Art in the Treatment of Disease.' The author of that little volume, in clear and vigorous language, with pitiless logic, characteristic truthfulness, and fearless candour, pointed out the evils resulting from what he called the over-active perturbative treatment and the mischievous polypharmacy which were then prevalent. Sir John Forbes lamented that in his day a purely expectant treatment of disease was rarely practised, except under other colours and under other names; and he referred to the results of homœopathic treatment, which he looked upon as simply inert, in proof of the proposition that "the power of Nature to cure disease is infinitely greater than is generally believed by the great body of medical practitioners and by the public. So great, indeed, is this power," he goes on to remark, "and so universally operative, that it is a simple statement of facts to say, that of all diseases that are curable and cured, the vast majority are cured by Nature independently of art; and of the number of diseases that, according to our present mode of viewing things, may be fairly said to be curable by art, the far larger proportion may be justly set down as cured by Nature and art conjointly."

Since the publication of Sir John Forbes's book, and partly, no doubt, in consequence of that publication, our views as to disease and its treatment have undergone a very great change. A purely expectant treatment is now as common as then it was rare. It is now fashionable and orthodox to trust to the curative powers of Nature, and to doubt the therapeutic power of art. The pendulum has swung from one extreme to the other. At that time it was said, that according to the vulgar notion, the function of the physician consists in little else than the prescription or administration of drugs, and the function of the patient in little else than swallowing them." Now, on the contrary, that which was once said satirically, has come to be an almost accepted rule of practice; namely, that "the chief business of the physician is to amuse the patient while Nature performs the cure."

Now it is a very noteworthy fact that, simultaneously and side by side with this firm belief in the almost all-sufficiency of Nature and the impotence of art, there notoriously exists an extreme unwillingness to admit that any phenomena of disease can rightly be considered as having a conservative or curative tendency, so that to speak of pathological processes as curative efforts of Nature, "is a mode of looking at the phenomena of disease always suspiciously cross-examined at the present day."

But surely there is, *à priori*, good reason to believe that in the curative process of Nature there is an orderly method of procedure, of which, by a diligent search, we may gain some useful knowledge.

We are all too apt to forget that disease is a natural, although an abnormal condition of the body; that pathology is, in fact, a department of physiology, and that the phenomena of disease result from the action of the normal structures and forces only modified by morbid conditions.

Dr. Johnson then instanced some very obvious and well-known phenomena as examples of morbid processes having a conservative or curative tendency, and expressed an opinion that, as practitioners of medicine, they had something more to do than to watch the phenomena of disease as passive spectators, and that in their endeavour to prevent, to mitigate, and to cure disease, they had a better guide than mere empiricism.

He concluded by saying, I have suggested that a belief in the power of Nature to cure all curable diseases is inconsistent with a disbelief in the existence of morbid processes having a conservative or curative tendency. I have indicated various pathological phenomena the conservative tendency of which appears to me indisputable; and I have endeavoured to show that, by a careful study of the functional and structural changes which result from disease, we may obtain most valuable indications for treatment,—learning thereby both to do that which may aid Nature and to avoid such means as may tend to thwart and hinder the natural curative processes.

Again, I have intimated that it is difficult, and, as it seems to me, impossible, to reconcile a disbelief in the elimination of morbid poisons with a belief in the spread of disease by contagion. Confirmatory evidence as to the elimination of morbid poisons is afforded by the disastrous results of repressive methods of treatment. To take all possible precautions to exclude the cholera-poison from the system, and then, when once it has gained an entrance, to endeavour to retain it there by opiates and astringents, are practical modes of procedure utterly inconsistent with each other; unless, indeed, the object of this repressive treatment be to sacrifice the individual for the public good—to prevent the patient, at the peril of his own life, from scattering the seeds of disease and death among the community.

I believe that the success of our attempts to cure and to prevent disease depends mainly upon an exact diagnosis and discrimination of the various forms and shades and stages of disease; upon a correct interpretation of pathological processes and symptoms; a careful avoidance of erroneous and misleading theories; and, lastly, upon a prompt recognition of the exciting causes of disease, some of which may be avoided, some removed, while the influence of others may be in a greater or less degree counteracted by the timely employment of suitable means.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Petroleum Bill.—The Petroleum Bill was read a second time on Thursday, August 10; passed through committee on Tuesday, August 15; and was read a third time and passed on Wednesday, August 16.

Poisoning by Carbonic Oxide.

On Saturday, August 29, a labourer, named John Howie, employed in the iron foundry of Messrs. Law and Co., Glasgow, was found dead under circumstances that have led to the conclusion that he was poisoned by carbonic oxide. It is supposed that on Friday, Howie, to prevent interruption while at dinner, had shut himself up in a spare room, and was not missed until the following morning. He was then found dead. His face, the front of the left side of his breast, shoulder, and the front of the upper part of his left arm, were red, and appeared to have been scorched, and the cuticle was peeling off. There were no other marks on the body. In the apartment in which the body was found there was a very strong, rapidly-sickening smell, which appeared to be caused by some chemical gas. The medical man called in was of opinion that the scorched appearance upon the face, shoulder, and arm might have been caused by the chemical action of such gas, or by heat from a fire.

This suspicion of air-poisoning was strengthened by the fact that on the previous day several of the *employés* of the Messrs. Law were seized with retching and vomiting, from which they recovered under medical treatment. In the afternoon an investigation was entered upon by Dr. T. E. Thorpe, Professor of Chemistry in Anderson's University. The works of the Messrs. Law are entered by a gateway carried under the front building. On one side of this entrance, and inside the gateway, is the office, in which several of the *employés* were seized with illness on Friday. Adjoining this office is the little room in which Howie was found. Beyond the office, and separated from it by a brick wall, is a large smith's shop, also connected with the works. In this smithy some of the men working near the dividing wall complained of the prevailing sickness, while others who were further removed from the office appeared to escape. Passing through the entrance gateway the centre of the works is reached, a considerable unroofed area, surrounding which are several buildings, in which the various departments of the works are carried on. One of these is a small erection containing a blasting apparatus, which, by means of earthenware pipes carried underground, acts upon a furnace at the further end of the yard. Standing nearly midway between the blast and the furnace is a heating-room, in which articles are prepared for the "dressers" by being subjected to an intense heat, and while in this state are placed on the floor to cool. The heat is communicated to the floor, which is of iron, and at times it is said to have become red-hot. The greater portion of the site on which the works are erected is forced earth, the product of what is known as a "free coup," and contains a large quantity of cinders. It is therefore of an open, porous nature, and peculiarly liable to the action of heat.

In the room in which the body of Howie was found, nothing particular was at first observed. In the course of previous inquiry, the window-panes had been broken and the door thrown open, in order to promote the escape of foul air from the apartment. To restore the room as far as possible to its former condition, the door was closed, the place of the broken window-panes was supplied with straw and the blast was set in operation. A short time having elapsed, Dr. Thorpe entered the room, and in two or three minutes was seized with headache and a feeling of giddiness and oppression about the head. The smell was of a peculiar kind. It was apparent, therefore, that the poisonous influence, whatever it might be, was specially present in this room. A pigeon was thrown into the room and the door shut, and in forty-five seconds it was found to be dead. A dog was next shut up. In about half a minute the animal began to moan—at first loudly and then less audibly—and in two minutes and a quarter it also was found to have succumbed. Pushing his inquiries further, Dr. Thorpe caused the soil in the neighbourhood of the heating-room to be upturned, and here it was found that a layer of earth, principally cinders, had ignited and gave out a whitish smoke. It also appeared that the underground pipes, through which the blast operated upon the furnace, were cracked by the heat, so that when the blast was set going the leakage released the gases generated in the earth, and these, the combustion being imperfect, would be mainly carbonic oxide. Near the source of escape the main line of pipes from the blast is intersected by a forked line of piping, which is carried back to the smith's shop, terminating under the brick wall formerly described as separating the office from the smithy. At this point some of the mortar between the bricks was found to have been dislodged, and in this way the gas which had been conveyed through the fork-line of pipes was distributed in the office and the little room in which Howie was found dead.

After the experiment with the dog had been made as already stated, the door of the room was opened and the poisonous gas allowed to escape, the operation of the blast also being suspended. The room was again shut up. A dog was imprisoned for the night, in the morning he was found unhurt. The conditions of this experiment were exactly the same as before, with the significant exception that the blast was not going.

The Alleged Poisoning by Arsenic at Cambridge.

This case has, after a prolonged investigation, resulted in the discharge of the prisoner. At the last examination Mr. Edmund Foster, the solicitor for the prosecution, said that he had communicated with Professor Letheby, and requested him to make an analysis, and asking what portions of the body he would require. In consequence of Dr. Letheby's reply, there were sent to him the pudding, the vomit, and various parts of the body which have been mentioned. Dr. Letheby afterwards made a report, in which he said that he was unable to find poison in any of the matters submitted to him.

Professor Liveing said that the result of his second analysis being inconsistent with that of the first, and also inconsistent with the opinion of another experienced chemist, and the whole quantity of arsenic found being so exceedingly minute, he could hardly avoid the conclusion that it was accidentally present, even though he could not point out how it might probably have arrived there. This opinion he gave as the result of his experience. He ought also to state that the whole quantity found might be taken by any one with perfect impunity.

The Bench, after consulting a short time, decided to discharge the prisoner, but gave her to understand that she would be re-arrested if any other evidence were forthcoming.

Poisoning by Carbolic Acid.

A case of poisoning occurred at Newcastle, on Friday, the 11th inst. A child, named Anthony Grady, three years and two months old, son of a labourer, about two o'clock asked his mother for some bread and sugar, which she gave to him. The child then went upstairs into the house of a neighbour, where there had been a case of smallpox, and found lying behind the door a bottle of carbolic acid, which had been sent for disinfecting purposes. A neighbour living next-door heard the child shouting "Biddy, Biddy, my mouth," and immediately ran to it, and found it suffering from the effects of the poison. About half-past three o'clock it was taken to Dr. Gibbs's, but at that time it was sinking very fast. All the means likely to save the child's life were used, but without effect, and it died in great agony."—*Standard.*

The Pharmacy Bill.

Sir,—I have read with much interest the numerous letters which have appeared in your journal relative to the Amended Pharmacy Act, and can only express my surprise at some of your correspondents, who seem to treat the matter with the utmost contempt, ignoring Government representatives who have received them as gentlemen, and, with regard to the Bill, have rather acted than said, "Come, and let us reason together." Reason and common sense seem to me to have been thrown entirely on one side by the so-called Chemists' Defence Association,—so much so, indeed, that I think defence should rather read defiance; for some of these gentlemen appear as though they would fly directly in the face of those who, but a few years since, placed pharmaceutists essentially on their legs, instead of quietly reflecting and asking themselves the questions, What is it Government proposes to do? and, What are the objections to such propositions?

Perhaps, Sir, you will pardon my trespassing on your space with a reply to these two questions.

What is it that Government proposes? In the first place, I may say it is no new thing, for the Pharmacy Act of 1868 required, and no one then discussed the matter, that compulsory regulations should be provided by the then constituted governing body—the Pharmaceutical Society of Great Britain. This Society, up to the present date, has failed to fulfil its contract; and, naturally enough, has been called over the coals. Where was the honesty of the accepted contract, unless those who accepted it fully intended complying with, and carrying out to the letter, its requirements? And now we find Government is determined (although the Bill is quietly put on the shelf this session, until those who now denounce it as monstrous and inconsistent with liberty have come to reason) to bring in their own Bill, to make complete that Act which in honesty they agreed the Pharmaceutical Society should do; and the old saying comes true again with regard to master and man, "If you want a thing done properly, do it yourself."

What are the objections to these propositions, for compulsory regulations?

With regard to them, Mr. Sandford has plainly told us, and others have repeated the same, that when Mr. Forster was approached in a courteous common-sense manner, he appeared most willing, as a gentleman, to discuss in a proper spirit the merits of the Bill, and to withdraw such objections as he found necessary for the interests of the pharmaceutists as a body; but this mode of procedure was at once thrown on one side by an infusion of bad blood, demanding the strongest opposion to the Bill itself in a manner, I consider, quite inconsistent with the character of Englishmen,—and thus ignoring the very contract which granted to the Pharmaceutical Society its present elevated position, and which contract required of those accepting it that compulsory poison regulations should be part and parcel of the same bargain.

I think, Sir, we are unfair and unjust in such hasty action, and I most cordially agree with Mr. Sandford, and admire his manly, honourable, straightforward action; for, at the bottom of it all, I believe he has the real welfare of the Pharmaceutical Society at heart.

Let us not harbour in our Society hard and harsh words,—"treason" and "treachery,"—but rather act in unison, conceding and accepting for our mutual good, and the welfare and advancement of pharmacy. Then, I think, we shall see some of our good old friends, whose names as correspondents and workers, to me, have been conspicuously prominent of late by their absence, working again amongst us.

Arthur Wm. Postans.

35, Baker Street, W.

Sir,—In candour I am bound to admit Mr. Giles's criticism of my letter is so far correct that there is no mention of inspection in the Pharmacy Act Amendment Bill. Whether the passing of the Act would lead to such a degradation, is a question which chemists should seriously consider.

As to the fetters the proposed Act would really impose, when so gentlemanly an advocate as Mr. Giles says "they won't hurt you," no wonder his happy confidence is somewhat contagious. The Act, some may think, would not be enforced; it has no teeth, and therefore even Mr. Simon could not make it bite.

But surely it were the part of wisdom to look into this before, rather than after, its infliction; to submit it, at least, to a previous qualitative analysis. Does it contain the elements of informations? Has it a trace of penalties? Is it at all forwarded by summary convictions? If so, whether through official inspection or otherwise, it is not a thing to be assumed with a "light heart."

The time will probably come when the amenities of the Privy Council Office will be regarded as dangers escaped; when the attempt to encumber chemists with restrictions, while the necessity for them was fast vanishing, will be seen as a monstrous injustice; and when even Mr. Giles will discover that "loyalty to pharmacy" is best observed neither by inviting legislative interference, nor by willing submission to compulsory regulations.

Glastonbury, August 14th, 1871. T. Mayhew.

Sir,—There is a difference of opinion as to whether the Pharmacy Act of 1868 required as a matter of necessity, or only provided as a matter of possibility, that further regulations for the dispensing and storage of poisons would be framed; but if it be necessary to consider the amendment of the Bill, that circumstance certainly affords the opportunity of reconsidering whether or not it would be advantageous to enact regulations such as it is said were contemplated, the real problem, both for ourselves and for Parliament, being the greatest good to the greatest number.

Seeing that the signers of Mr. Sandford's circular in favour of the "Bill to amend" have sought the aid of Parliament to impose upon themselves and their neighbours a code of additional regulations which they say are free from objections, and would be highly conducive to public safety, it is reasonable that we who have taken an opposite view of the practical value of the proposed measure should give a candid consideration to what they may be able to describe as their experience of the working of the proposed code.

As far as my experience has gone, I have not been favourably impressed with the regulations; and though I would at any time have read with interest an account of the experience of my neighbours, I have as yet only met with general expressions of approbation, without such particulars as would enable me to judge of the way in which the details of the scheme are carried out.

The circular states that the regulations were taken from the systems practised in the best-regulated establishments, and I think we may legitimately conclude that the signers mean their own establishments, which we willingly admit are many of them eminently well conducted, and under most favourable circumstances for a satisfactory trial of the proposed plan. As there is a very large number—I believe I might say a very large majority—of the trade who do not agree with the signers of the circular, we may reasonably request some of the latter gentlemen—say the first six on the list—to give a detailed account of how the regulations work in one or two of the points which have been most objected to.

I take the first six signatures on the list,—

Allen and Hanburys,
J. B. Barnes,
John Bell and Co.,
W. L. Bird,
Blake, Sandford and Blake,
Bolton and Co.,

and respectfully invite them to communicate to the Journal, or to myself privately, for public good, details of the precautions they use in the storage of each of the following poisons, and also—for comparison—the precautions, if any, observed in the storage of the subjoined list of drugs which are not poisons. As I do not wish to trespass unreasonably on their time, I limit my list of poisons to the official preparations of one Natural Order, and my list of non-poisonous drugs to a small number, which may be instructive by comparison; and I should feel it perfectly satisfactory if the particulars were furnished by the chief assistant or manager in each establishment:—

Poisons.

Decoct. Papaveris.
Extractum Papaveris.
Syrupus Papaveris.
Opium.
Confectio Opii.
Emplastrum Opii.
Extractum Opii.
,, ,, Liquidum.
Linimentum Opii.
Pilula Ipecacuanhæ cum Scilla.
,, Plumbi cum Opio.
,, Saponis Composita.
Pulvis Cretæ Aromat. cum Opio.
Vinum Opii.
Suppositoria Plumbi Composita.
Morphiæ Acetas.
Liquor Morphiæ Acetatis.
Morphiæ Hydrochloras.
Liquor Morphiæ Hydrochl.
Suppositoria Morphiæ.
Trochisci Morphiæ.
,, Morphiæ et Ipecacuanhæ.

Drugs not Poisons.

Extractum Physostigmatis.
,, Nucis Vomicæ.
,, Stramonii.
Hydrargyri Sulphas.
,, Nitratis Acid. Liquor.
Ol. Crotonis.
Linimentum Iodi.
Acid. Carbolicum.

If, in response to this request, we should be favoured with the experience of these, or any other firms of noted standing, it would be most desirable to have the replies drawn up without intercommunication, as diversity or coincidence of experience would thus be most instructive, and would be likely to lead ultimately to greater unanimity.

11, *Grey Street, Newcastle, August 15th,* 1871. Barnard S. Proctor.

Sir,—We have heard a good deal lately about the education of pharmacists, and yet, on looking back a few months and reading the correspondence on the Poison Bill, we cannot but admit that that education has signally failed.

"Ingenuas didicisse fideliter artes,
Emollit mores, nec sinit esse feros."

Does it indeed? If Ovid had lived in our day he never would have written that. A body of presumably educated men treat one another with the barest courtesy, and often with something far short of that, and why? because their opponents hold different opinions from themselves. Mr. Sandford is a "traitor," because he zealously works in aid of a cause which he believes best for the public weal. The Defence Association is a body of "misguided men" and "factious agitators," because they differ from Mr. Balkwill, and so on.

How very generous, how very liberal-minded we are getting with our education! I think if our pharmacists, one and all, had shown a little more respect for their opponents' opinions, the poison question would now be settled. As it is, I fear we shall have the same painful ordeal to undergo in the next session of Parliament.

Preston. An Apprentice.

Chinese Materia Medica.

Sir,—Adverting to Dr. Porter Smith's book on this subject, which received notice in your pages some little time since, may I be permitted to point out two or three errors, and—as I believe—correct them. I know how difficult it is in a foreign country, removed from books and civilized men, to produce a moderately good book on a scientific subject, but that is no reason why the imperfections of such work should be passed over. In the interest of science, it appears to me to be the duty of those who detect mistakes to apply themselves to their correction.

The remarks to which I desire to direct attention occur on page 140, and are to the following effect:—"*Lycoperdon giganticum* (Ma-peh). Species of Puffball and Truffle are met with in Central China. The brown broken, globular masses of this species of *Lycoperdon*, said to vary from the size of a Chinese bushel to that of a peck, are met with in the drug shops here in a dried and decayed state. They are full of the reddish-brown, powdery spores, which are employed as a dusting powder after careful sifting. They are given in affections of the gullet, larynx (aphonia), lungs, and in hæmorrhages. Sugar and honey are taken with this powder." Specimens of Ma-peh have somewhat the resemblance, at first sight, of a *Lycoperdon* or *Scleroderma;* indeed, the spores more closely resemble those of *Scleroderma geaster* than those of *Lycoperdon giganteum* (not *giganticum* as printed). The microscope would prove in an instant that the spores of the Ma-peh are not those of *Lycoperdon giganteum,* since they are echinulate and four times the size; again, the colour is so much brighter and more ferruginous; but the most conclusive evidence lies in the structure of the fragments themselves, in which will be found the remarkable inner peridia characteristic of the genus *Polysaccum.* In fact, the Ma-peh, or, at least, all that I have seen, is a true species of *Polysaccum.* The spores are just like those of *P. crassipes,* except that, perhaps, they are a trifle darker. Because, when ripe, this fungus, in common with its allies, becomes broken up and dusty, that is no reason for calling it "decayed;" the "decayed state" is manifestly an error.

The next article is a mystery. It is thus described:—"*Lycoperdon squalmatum* [*sic*] (Kiuen-peh). The whole plant of this fungus, with its mass of brown fibrous roots and green branching curved, compressed fronds, with furrowed, acuminate, hygrometric scales, is likened by the Chinese to a fir. It grows to the height of some six or eight inches on stones, and is collected for medicinal use at Ningpo, although it is met with all over China. A large trade is carried on in all sorts of drugs between Hankow and Ningpo, second only to that between Siang-tan and Hankow. It is given as an emmenagogue, cordial, deobstruent, and tussic remedy. When scorched or dried artificially, astringent properties are assigned to this harmless substance." Harmless it may be, but curious it must be, if it claims to be a fungus and a *Lycoperdon,* with green branched fronds, covered with hygrometric scales. The Chinese are a marvellous people, and few nations could compete with them in the production of a green *Lycoperdon* with scaly branched fronds. Is it possible that Mr. Porter Smith can have made the mistake of calling it a fungus, and referring it to the genus *Lycoperdon* instead of the *Lycopodiaceæ!* It might be so, only that the author distinctly call it a "fungus,', and it would be uncharitable to suppose that he could not distinguish at a glance a fungus from a Fern or a Lycopod.

As to the Chu-ling (p. 171), which happens to have much more in common with the Fuh-ling than "half the name," I must refer Mr. Smith to the third volume of the 'Journal of the Linnean Society' (Botany) for information.

M. C. Cooke.

Pharmacy in France during the War.

Sir,—It may not be generally known that the provincial pharmacists of France suffered much loss and inconvenience from the investment of Paris by the German armies. I allude to those living without the pale of the enemy's incursions; of the miseries endured by those gentlemen who found themselves in the actual presence of the dreaded foe, and among all the positive and immediate horrors of war, I am scarcely competent to speak. It is well known that, beyond the fact of Paris being the bureaucratic centre of France, the provinces depended on the capital for nearly all that tends to make life comfortable and luxurious. Paris, if not the source or seat of manufacture, was at least the chief *entrepôt* of all drugs, chemicals and pharmaceutical accessories; hence it is easy to divine the difficulty experienced by country pharmacists in renewing their exhausted supplies. I am able to speak personally of the occasional impossibility of procuring preparations such as the morphia alkaloids, pure carbolic acid, quinine and, most especially, chloral hydrate. This last was much prescribed in the locality (a town in the south of France) in which I passed the winter, and at times, in spite of much begging and borrowing from our *confrères* of Lyons, Marseilles, Bordeaux, and the neighbouring towns, our stock of it ran completely out. The little now and then obtainable cost from 3·50 francs to 5 francs per 30 grammes. It was quoted in England about this time at 11*s.* per lb. Towards the end of the season, however, we were fortunate enough to meet with a small parcel imported in an indirect manner from Berlin—of all places in the world!—of very excellent quantity.

Parisian specialities rapidly became scarce and very dear, their trade-value ruling higher than the ordinary price to the public. The more popular of these articles soon disappeared entirely from the market.

Some of the most current remedies of a French pharmacy being prepared in the form of syrups and *pâtes,* the very high price of refined sugar towards the end of the war augmenting their value was the subject of much complaint on the part of the poor peasants, to whom a few sous represent many hours of weary labour. It may be suggested that supplies might have been derived from Italy, Switzerland or even Spain; but these countries really depend almost as much upon Paris as France itself. England, of course, could have furnished her unfortunate neighbour to an unlimited extent, and probably did partially supply the north of France; but very little English produce found its way to the extreme south, owing in part to defective means of transport, and in part to the paucity of business relations between England and the locality in question.

Walter A. Powell.

The Weights of the British Pharmacopœia.

Sir,—Will you allow me, through the medium of the Journal, to point out a few of the disadvantages, and even dangers, of the present system of weights in the P. B.? For instance, in making one-fourth of the quantity of pilula saponis comp. many chemists would put 5 grains of opium too much, by reckoning 480 grains to the ounce instead of 437·5, and the same mistake would happen in making small quantities of many of the P. B. preparations. It is a constant source of annoyance to the pharmacist in making small quantities of preparations for immediate use to have to enter into a long calculation to arrive at the proper quantities of the ingredients.

I hope that when a new edition of the P. B. is contemplated the Pharmaceutical Society will use its influence, and endeavour to have the metric system used in it, which is as easy to learn as the alphabet; and I think that if the Society would petition Parliament, in the manner they did to throw out the Pharmacy Bill, for the adoption of the metric system, and not only chemists signed the petitions, but every one who was willing, it would be carried the next time it is brought before Parliament. Why should not candidates for the Preliminary Examination be required to possess a knowledge of the system instead of those for the Minor? they cannot be expected to succeed to any great degree in their after studies unless they possess a practical knowledge of it.

Gramme.

"*Galvanic.*"—A correspondent, under this signature, suggests that "an idea which might be carried out without much expense would be to have a galvanic battery to which all the bottles containing the most powerful poisons might be attached, so that when the dispenser had occasion to handle one he would receive a slight shock which could not fail at all times to attract his attention, if diverted from the subject in which he was engaged."

"*One of the Candidates.*"—We would recommend you to forward your complaint to the Council, with whom the decision in the matter rests.

"*Minor Exam.*"—Apply to the Secretary for a Synopsis of the Examinations.

G. R. C. will find the recipes asked for in Vol. I. pp. 477 and 496.

W. H. Wilson.—See a case reported Pharm. Journ. 3rd ser. Vol. I. p. 775.

"*Pharmacist.*"—In each of the first four lines of the copy of prescription sent, the quantity is the direct object of the transitive verb; in the fifth line the word "aquam" is the direct object. The M.D.'s view is therefore correct.

E. H.—The precipitation is caused by the chemical affinity of the oxide of lead for the colouring or extractive matter; such compounds are almost invariably insoluble, hence subacetate of lead will completely decolorize in nearly every case. Yes.

NIGELLA SEEDS OR BLACK CUMMIN.

BY DR. F. A. FLÜCKIGER,

Professor in the University of Bern.

These seeds which had a place in the Bengal Pharmacopœia (1844), are included in the Pharmacopœia of India (1868) among the "non-officinal" articles. But as they are still of considerable importance in the East and are even in use in some parts of Europe, I have thought that a few particulars regarding the experiments I have made upon them may not be uninteresting to the readers of the PHARMACEUTICAL JOURNAL.

Name.—In pharmacy they have been termed *Semen Nigellæ*, s. *Melanthii*, s. *Cumini nigri*. In English the plant bears the name of *Nigella*, *Black Cummin*, *Gith*, or *Bishopswort;* in German the seeds are called *Schwarzkümmel* or *Nardensame;* in French *Cumin noir*, *Graine de Nigelle romaine*, or *Poivrette*. Most of the Indian names signify when translated *Black Cummin.*

Botanical Origin.—*Nigella sativa*, L. (*N. indica*, Roxb.), belongs to the Order *Ranunculaceæ* and is an annual herb, 8 to 12 inches high, with leaves cut into numerous, narrow, pinnate segments. The flowers are solitary, terminal, without an involucre; the petals blue and white, with greenish glands. The capsule is formed of 3 to 6 carpels, opening by the ventral suture. The plant grows on the Mediterranean coasts, in Egypt and Trans-Caucasia, whence it has spread to India. Boissier* regards the var. β *brachyloba*, occurring in Cilicia and Syria, as the original type of the plant in a wild state.

Nigella sativa is now widely distributed as a cornfield weed throughout temperate Europe and America, though not in Britain. In Germany it is cultivated to some extent near Erfurt.

History.—Nigella is thought by some to be the *kezach* of Isaiah (xxviii. 25), translated in the English Bible *fitches*.

Dioscorides described the plant clearly under the name of Μελάνθιον. Pliny called it *Git*, under which appellation it is found among the plants which Charlemagne ordered to be cultivated on the imperial farms of his dominions. This name however, was frequently applied in the middle ages to the Corn Cockle, *Agrostemma Githago*, L., which is indeed termed by Gerarde *Bastard Nigella*. In his time, nigella was commonly sown in gardens, the seeds being used medicinally in wine as a spicy stimulant, and also as a perfume, for he says "it serveth well among other sweets to put into sweet waters, bagges and odoriferous powders."

Nigella seeds had a place in the London Pharmacopœia as late as the edition of 1721. In the East, the seeds have been extensively used from the remotest times to the present day.

Description.—The seeds are about $\frac{1}{10}$th of an inch long, of an irregular compressed pyramidal form, 3- or 4-sided, with an oblique rounded base, whence sharp ridges proceed towards the blunt summit of the seed. The surface is black, rough, granular, and devoid of polish. The seeds have an aromatic taste, and, when crushed, considerable fragrance.†

Microscopical Structure.—The albumen consists of large polyhedral cells, and is covered by a thin brown tegmen. The testa presents two or three rows of more or less thick-walled cells; the inner being elongated in a direction parallel to the surface of the seed, the outer vaulted and a certain number of them, chiefly those forming the ridges, prominently conical. The whole testa is blackish or dark bluish. The embryo is situated near the apex of the seed.

The tissue of the albumen abounds in fat oil and in granular albuminous matters; it is not altered by a salt of iron.

Chemical Composition.—Reinsch in 1841 obtained from this seed 35·8 per cent. of fat oil, 0·8 per cent. of volatile oil, and only 0·6 per cent. of ash. He gave the name of *Nigellin* to a bitter extract resembling turpentine, yet soluble in water as well as in alcohol, though not in ether.

By submitting 25 lb. of fresh seed to distillation, I obtained a nearly colourless essential oil in even smaller quantity than *Reinsch*. It has a slight odour, somewhat resembling that of parsley oil, with a magnificent bluish fluorescence, as already remarked by Reinsch.

In a column 50 mm. long, this oil deviates the ray of polarized light 9·8° to the left. Its specific gravity is 0·8909. The chief part of it, when distilled with chloride of calcium in a current of dry carbonic acid, comes over at 493° (256° C.) In an elementary analysis* it yielded: carbon: 83·3, and hydrogen: 11·8 per cent., corresponding to the formula $2\ C_{10}H_{16} + H_2O$.

The residual portion was almost entirely devoid of deviating power; it yielded carbon: 87·89, and hydrogen: 11·72 per cent., after having been rectified by means of sodium. This part of the oil consequently belongs to the formula $C_{10}H_{16}$.

I extracted the fat oil, by means of boiling ether, from seed grown in Germany, previously finely powdered. The oil thus obtained which necessarily included some essential oil imparting to the other its fluorescence, amounted to 25·6 per cent. It is a fluid fat which does not congeal at + 5° (− 15° C.); it was found to consist chiefly of olein, besides which it yielded a considerable amount of a solid fatty acid, the crystals of which, after reiterated purification, melted at 131° (55° C.). The melting point did not rise by recrystallization, the acid being probably a mixture of palmitinic and myristic acids.

Nigella seeds, powdered and dried over sulphuric acid, yielded 3·3195† per cent. of nitrogen, answering to about 21½ per cent. of albuminous matter.

Uses.—It is stated in the Pharmacopœia of India, that nigella seeds are carminative, and they were formerly so regarded in Europe. In the East generally they are used as a condiment to food, and in Greece, Turkey and Egypt they are frequently strewed over the surface of bread and cakes in the same manner as anise or sesame. The fixed oil of the seeds is also expressed for use.

I have no recent statistics indicating the extent to which the seed is grown, but may state, on the authority of an official French document, that during the year 1854–55, 83 quarters, worth 2592 rupees, were exported from Madras to Ceylon.

* Flora Orientalis, i. 68.

† Those of the nearly allied *N. Damascena*, L. are rather more ovoid, less sharply ridged, less aromatic, and not pungent.

* Performed in my laboratory by Dr. Kraushaar.

† On an average of three experiments made in my laboratory.

HIMALAYA TEA.

BY T. ZOELLER.

The May number of the *Annalen der Chemie und Pharmacie* contains the result of an interesting investigation on Himalaya Tea, by Th. Zoeller, which is of considerable value.

The author begins by stating that the opinion that the different sorts of tea are derived from various species of the tea-plant had been refuted by Siebold, and more completely still by Fortune's inquiries. Black and green tea are both derived from *Thea sinensis*, and the many varieties of tea in the trade are not products of different plants, but merely results of differences in climate, soil, cultivation, and in the preparation of the leaves, but, above all, of age. Although the tea-plant itself is hardy enough to bear considerable fluctuations in temperature, still, the quality of the leaves greatly depends upon the soil, cultivation, and, as stated just now, upon the age, while their preparation has no effect upon the quality, but only alters the outward form. Zoeller had previously shown that with beech-leaves the composition of the ash constantly changes with the age or development in the leaves, inasmuch as the amount of potash and phosphoric acid gradually decreases with progressing age, while lime and silica constantly increase in quantity. Taking this observation as his basis, Zoeller concludes that if the quality of tea is in the inverse ratio to the age of the leaves, the analysis of the ashes of it must enable us to determine the age, and consequently the quality. A high percentage of potash and phosphoric acid with little lime would indicate a young tea, or a superior quality; while, on the other hand, much lime and little potash would be the characteristics of an inferior quality. The author succeeded in obtaining some samples of Himalaya tea, collected when very young, and the analysis quite bore out his anticipation. These leaves had been gathered very early, the lanceolate form was not quite developed, they were of a fine black colour, and produced with hot water the most delicate aroma.

The analysis gave 4·95 per cent. of water, and 5·63 per cent. of ashes, containing much potash and phosphoric acid, and little lime; boiling water extracted 36·26 per cent., of which 4·94 per cent. was theine. To separate the alkaloid, the cells of the leaves were completely broken up by maceration with concentrated sulphuric acid; the acid was then neutralized by moist hydrated oxide of lead, and the mass repeatedly extracted with alcohol; the alcoholic extract was treated with animal charcoal, and after filtration slowly evaporated, when most of the theine separated in shining silky needles.

Further evaporation did not yield any more crystals, because the sugar, formed by the action of sulphuric acid upon cellulose interfered, and made the solution too syrupy; the rest of the theine was therefore separated by ether. The alcoholic extract on standing over-night deposited crystals, which Liebig took for theobromine; although the minuteness of the quantity prevented exact determination, the observation is important, as the presence of theobromine in tea had not before been shown. The nitrogen in the tea leaves amounted to 5·38 per cent.

The complete analysis of the different constituents showed the following results, viz.:—

	Ash of tea leaves.	Ash of aqueous extract.	Ash of leaves after extraction.
Potash	39·22	55·15	7·34
Soda	0·65	0·68	0·69
Manganese	6·47	3·13	11·45
Lime	4·24	0·95	10·76
Oxide of Iron	4·38	1·73	9·53
Oxide of Manganese	1·03	0·43	1·97
Chlorine	0·87	0·57	traces
Phosphoric Acid	14·55	7·89	25·41
Sulphuric Acid	traces	traces	traces
Silica	4·35	2·92	7·57
Carbonic Acid, etc.	24·30	26·30	25·28
	100·00	100·00	100·00

Percentage of Nitrogen.	Air-dry leaves.	Dry extract.	Exhausted and dried leaves.
Nitrogen	5·38 p.c.	10·09 p.c.	3·48 p.c.
Ash	5·63 „	11·46 „	3·06 „

100 parts of ashes of the leaves are composed of 30·82 parts of ashes of the exhausted leaves, and 69·18 parts of ashes of the extract.

The results lead to the conclusion that Himalaya tea is quite equal to the best Chinese tea, but it must remain undecided whether the presence of theobromine is accidental, or constitutes a distinction; the results also bear out the experience of tea-planters, that the youngest leaves of the tea plant give the best quality.

In the determination of the age of the leaves by analysis of the ashes the amount of potash must always be compared with that of phosphoric acid and lime, because the older plants often show a high percentage of potash if grown on soil rich in potash salt, but the amount of lime and phosphoric acid invariably decreases according to the age.

Remarkable and characteristic of the ashes of tea is the large quantity of iron and manganese. The effect of iron in the infusion of tea upon the vital functions has been noticed by Liebig in his 'Chemical Letters,' and the importance of iron in vegetal life is well known, whereas that of manganese has not yet been ascertained.

In making infusions of various samples, they show a difference, inasmuch as the best tea was most readily exhausted. The component parts of the ashes are dissolved in different proportions; chlorine almost entirely, potash very considerably, lime, magnesia and phosphoric acid but slightly. The different solubility affords a ready means to distinguish exhausted leaves from not exhausted ones; and this may be of practical importance, as exhausted tea is often made up and brought again into the trade. The ashes of exhausted leaves contain but little potash, but much of the above-named insoluble substances.

In reference to the action of tea upon the human system, the author again points to the richness in potash, the importance of which in nutrition has been demonstrated by Kemmerich's experiments. But as the infusion of tea contains but little phosphoric acid, the alkali is enabled to convert the acid phosphates of our food into less acid ones, *i.e.* into those which act as solvents of insoluble albumen, and which form part of the normal conditions of blood.

Hot water dissolves 3·56 per cent. of nitrogen; tea contains 4·94 per cent. of theine, equal to 1·73 per cent. of nitrogen; the difference in nitrogen, namely 2·14 per cent. is, according to Peligot, part of caseine, and corresponds to 13·7 per cent. of caseine, a quantity sufficiently large to play an important part in the process of nutrition.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

LIQUOR SODÆ CHLORATÆ.

A solution of chloride, hypochlorite, and bicarbonate of sodium, obtained by passing chlorine gas into a cold solution of carbonate of soda.

$$Na_2CO_3 + Cl_2 + H_2O + Na_2CO_3$$
$$= NaCl + NaClO + 2\,(NaHCO_3).$$

Properties and reactions similar to those of calx chlorata.

LIQUOR ZINCI CHLORIDI.—Granulated zinc is dissolved in hydrochloric acid, and the iron and lead, which are usually present, removed by addition of chlorine water, and digestion of the solution upon excess of carbonate of zinc. The foreign metals are in this way thrown out of solution as hydrated oxides:—

$$2\,(FeCl_2).Cl_2 + 3\,ZnO.CO_2 + xH_2O$$
$$= Fe_2O_3xH_2O + 3\,ZnCl_2 + 3\,CO_2,$$

and

$$PbCl_2.Cl_2 + 2\,ZnOCO_2$$
$$= PbO_2 + 2\,ZnCl_2 + 2\,CO_2.$$

After filtration the liquid is evaporated to the proper bulk.

The solution contains 175 grains of zinc, or 366 grains of chloride of zinc, in a fluid ounce.

LITHIÆ CARBONAS.—The minerals from which lithium is obtained, are silicates of aluminium and one or several of the alkali metals, part of the sodium or potassium being replaced by a chemically equivalent quantity of lithium. One of the best methods of treating these minerals consists in heating the finely powdered material with quicklime and a little chloride of calcium. The alkali is thus rendered soluble in the form of chloride, and can easily be converted into any compound that may be required.

[§ In white powder or in minute crystalline grains, alkaline in reaction, soluble in 100 parts of cold water, insoluble in alcohol. It dissolves with effervescence in hydrochloric acid; and the solution evaporated to dryness leaves a residue of chloride of lithium, which communicates a red colour to the flame of a spirit-lamp, and, redissolved in water, yields a precipitate with phosphate of soda.] Carbonate of lithia thus differs from the potassium or sodium carbonate in being but slightly soluble in water; it is also partially decomposed by long ignition, becoming converted into oxide.

Lithium salts are also distinguished from those of potassium and sodium by the sparing solubility of the phosphate and by the easy solubility of the platino-chloride.

LITHIÆ CITRAS.—Citric acid neutralized by the addition of carbonate of lithia and the resulting salt dried. A white deliquescent salt, blackening when heated, and when calcined with free exposure to air leaving a white residue of carbonate. 20 grains thus incinerated leave 10·57 grains.

MAGNESIA.—Carbonate of magnesia is heated to redness, till a portion taken from the middle of the crucible and allowed to cool, no longer effervesces with a dilute acid:—

$$(MgCO_3)_3Mg(HO)_2 4H_2O = 382, \text{ leaves}$$
$$4MgO = 160.$$

4 ounces, therefore, leave 1·67 or nearly $1\frac{3}{4}$ ounces.

[§ Dissolved in nitric acid and neutralized with a mixture of ammonia and chloride of ammonium, it does not give any precipitate with oxalate of ammonia or chloride of barium.]

The absence of lime and sulphate of magnesium or sodium is thus indicated.

MAGNESIA LEVIS.—[§ A bulky white powder, differing from the preceding preparation only in its greater levity, the volumes corresponding to the same weight being to each other in the ratio of three and a half to one.]

MAGNESIÆ CARBONAS.—Boiling solutions of sulphate of magnesia and carbonate of soda are mixed and evaporated to dryness. The residue, after thorough washing with boiling water to remove sulphate and excess of carbonate of sodium, is the salt required:—

$$\left.\begin{matrix} 3\,MgSO_4 + 3\,Na_2CO_3 \\ MgSO_4 + Na_2CO_3 + 5\,H_2O \end{matrix}\right\}$$
$$= \left\{\begin{matrix} 3\,MgCO_3 & 3\,Na_2SO_4 \\ MgO.5\,H_2O & Na_2SO_4 + CO_2. \end{matrix}\right.$$

The official carbonate is, therefore, not a simple carbonate, but a hydrate carbonate. A similar constitution belongs to all the precipitated carbonates, except those of barium, strontium and calcium.

A normal carbonate containing 3 mols. of water of crystallization, $MgCO_3.3\,H_2O$ is deposited in crystals by exposure of liq. mag. carb. to the air.

The only probable impurities are calcic carbonate and sulphate of sodium or basic magnesium sulphate. These are easily detected by dissolving in hydrochloric acid and then adding excess of ammonia and some oxalate for the first, or chloride of barium for the second.

MAGNESIÆ CARBONAS LEVIS.—Both this and the heavy carbonate possess the same composition and are partly crystalline.

THE ETYMOLOGY OF THE WORD OPODELDOC.

BY J. BORLAND.

A short time ago, as I was perusing some of the older volumes of the PHARMACEUTICAL JOURNAL, my attention was arrested by a reply which appears in notices to correspondents, Vol. VII. page 248, 1865.

The editor who then was there states, "We are unable to give the derivation of the term Opodeldoc."

Now, although I have read the Journal for many years, and always with that amount of careful attention which it merits, as the representative organ of pharmaceutical learning in all its phases, I had not previously observed this remark; and when I read it I felt a little uneasy and humiliated at the admission, and said to myself, by way of excuse,—probably, after all, our editor's philological learning has not been commensurate with his pharmaceutical; or, what is more likely, he has considered philology to be incompatible with pharmacy, and therefore needed not trouble himself in finding a positive answer to the inquiry made of him.

Not able to give us the derivation of such a commonplace household word as Opodeldoc! This I thought was *infra dig.*, words which, with a little vain-glory, I translated "not a very deep dig." I resolved, therefore, to take the task in hand, and dig for myself; and, as I had been able to satisfy my mind regarding the root and branches of such obscure pharmaceutical terms as "Tinker o'Falairy," "Glory o'Lyme," "Jessie Wit's Bark," "Ascetic-as-sid," and many others of a similar character, I thought there would be no difficulty in finding some clue to the parentage of Opodeldoc. I set about, therefore, consulting all the lexicons, dictionaries and works of reference that I could find, exultingly thinking that I would be able to solve the difficulty, and perhaps appear in print with a full and particular account of the birth and introduction to society of this apparently puzzling word. After much research, however, and the consultation of numerous works from which aid might fully be expected, I had to *knuckle in*, and, like the editor, acknowledge my want of success. I reconciled myself, it is true, to my sour grapes by finding the following terse remarks in Blancard's 'Physical Dictionary,' 9th ed., 1726, under the word "Opodeldoc'; "'Tis a fictitious name, having no real signification."

Having failed in the antique I tried the modern, but only to meet with similar want of success. Pereira was silent on the subject, Neligan was equally mute, and Christison did not even honour the word with *ink-shed*, as, so far as I can find, it is not once mentioned in his 'Dispensatory.'

I had learned, however, in my research that the word was employed by Mindererus, Paracelsus and other mediæval writers,—men who flourished at a period when the study of our ancient classics was considered to be of little use unless it could be made subservient to the introduction and employment of new and pedantic terms; and notwithstanding what Blancard says, I had come to the conclusion not to give any reception to the dogma of the spontaneous generation of words; that is, without assigning to them some primitive signification which might be ascertained if we could only brush away from them the rubbish with which time and change had obscured them.

As the speediest method of cutting the knot, I agreed, therefore, to avail myself of the scientific use of the imagination (which many have done before me in similar straits) and find roots for myself, taking similarity of sound as the basis of my operations; a course of action which, I know, is sometimes honoured with the remark, "As the fool thinks so the bell clinks."

I venture, therefore to suggest as the roots of this word Opodeldoc, *ὀπός*, juice, and *θέλγω*, I soothe or charm; Latin, *mulceo*. Syncopating the *s*, the word becomes *ὀποθέλγω*, and employing the adjective form we have *ὀποθελκτικός*, meaning the soothing juice or balsam. The syncopation of the final letter of the word *ὀπός* is found in several compound Greek words, such as *ὀπο-βάλσαμον, ὀπο-κάλπασον, ὀπο-κιννάμωμον, ὀπο-πάναξ* and others, and it would very naturally take place in the case of the word *ὀπο-θέλγω*, and besides, the mutation of the rough lingual *θ* into the softer medial *δ* is, though somewhat rare, not an unknown occurrence, especially in Æolic Greek; and though this be not a purely classical word, its compounders may possibly have fashioned it according to classic laws. Were we, then, to adopt this latter change, the word would become, using Roman letters, *opodelgo*, and conventionality or euphemism might lead to *opodeldo* or *opodeldoc*. Metamorphoses far more striking than this are to be met with in our present pharmaceutical nomenclature. We have liquorice from *glycyrrhiza*, fennel from *fœniculum*, chamomile from *chamæmelon* (the apple on the ground) and so on, and in a work recently published, Prior's 'Names of British Plants,' second edition, illustrations of the most curious kind are to be met with in almost every page.

These few remarks regarding the etymology of this word will, I hope, be considered as nothing more than suggestive; but if some of our London brethren, who have the resources of the British Museum library at their command and many other antiquarian stores, would only devote a little time and research to the subject, we might be enabled to remove its etymology from the domain of supposition and doubt to the region of fact and certainty, and I hope that very soen some one will do so and favour us with the result.

EXPERIMENTS WITH CARBOLIC ACID.

BY ANGUS MACKINTOSH, M.D., CALLINGTON.

In the interest of science, as bearing specially on the effects of carbolic acid on organic substances, I desire to record a few experiments, with their results, which I carefully performed with carbolic acid in November last, with the view of proving further to my own satisfaction certain chemical and physiological changes that I have observed in treating ulcers and severe surgical injuries with the acid. The results at which I arrived were published last year; and, in consequence, Messrs. F. C. Calvert and Co., the well-known chemists of Manchester, kindly forwarded to me several samples of the different preparations made by them, to be tried in smallpox, etc. I have now tested them in many cases of smallpox with almost unparalleled success, and also in various surgical operations; and, in justice to Messrs. Calvert and Co., must say that I consider their preparations immensely superior to any other of the acid yet given to the profession.

Having had reason for years to question the accuracy and correctness of the germ-theory of disease, and of the *modus operandi* of the antiseptic system of treatment, so ably brought before the profession by my respected teacher, Professor Lister, I last year called the attention of the profession to the fact that the beneficial effects of carbolic acid on wounds, etc. were not to be attributed solely to the destruction of atmospheric germs, but mainly, if not completely, to the chemical and stimulating effects of it on the constituents of the blood and surrounding parts. The following experiments confirm the opinion then expressed:—

CLASS I. *Experiment* i.—On November 8th, 1870, I mixed a quarter of a pound of bullock's blood (fresh) with two ounces of F. C. Calvert and Co.'s carbolic acid No. 5 (proportion, 10 of water to 1 acid), and covered the whole so as to admit no air. The temperature was 50 deg. *Result*, July 10th, 1871: No signs of putrefaction.

Experiment ii.—On November 8th, 1870, I mixed a quarter of a pound of bullock's blood (fresh) with two ounces of Calvert's carbolic acid No. 5 (proportion, 10 of water to 1 acid), and left the whole uncovered and exposed to the air. The vessels used in this and the previous experiments were placed side by side in the same apartment. *Result*, July 10th, 1871: Not the slightest signs of or tendency to putrefaction.

Experiment iii.—On November 9th, 1870, I weighed two ounces of lean fresh beef, and placed it in a pot with two ounces of carbolic acid (Calvert's No. 5, 10 water to 1 acid), and covered the contents completely from the atmosphere. *Result*, July 12th, 1871: The meat was perfectly free from putrefaction.

Experiment iv.—On November 9th, 1870, I weighed two ounces of lean fresh beef, and placed it in a pot with two ounces of carbolic acid (Calvert's No. 5, 10 water to 1 acid), and left the contents exposed to the air in the same apartment with Nos. 1, 2, and 3. *Result*, July 10th, 1871: There was no offensive odour nor putrefaction.

CLASS II. *Experiment* v.—In January, 1871, I excised from a man's left arm a non-malignant tumour weighing a pound and a half, and dressed the wound with thin muslin and Calvert's carbolic acid No. 5 (proportion, 30 of water to 1 of acid). The acid solution was dropped freely over the muslin many times during the day. The wound healed without suppuration or putrefaction.

Experiment vi.—I amputated an old man's middle finger in April, 1871, and dressed it in the same way as No. 5, with thin muslin, dropping the acid solution freely over the muslin several times throughout the day. The result was a perfect cicatrix, without any appearance of pus, suppuration or putrefaction.

Experiment vii.—A miner had both arms and face burnt in consequence of an explosion whilst blasting. The face was treated with linseed-oil and linseed-meal poultices, and afterwards with oxide of zinc ointment. A small quantity of pus could be detected. The arms were treated with carbolic acid and linseed-oil, 1 to 20. The muslin (the only covering) was always kept wet with the oil and acid. The result was a complete cure, without any pus or putrefaction.

These experiments, in combination with those which I published last year, have completely convinced me that the detailed plan of dressing wounds recommended by Professor Lister is absolutely unnecessary for the object of healing wounds by the first intention or without the formation of pus; and that the germ-theory of disease is, correctly speaking, an error.

In the first class of these experiments, I treated the blood and beef with exactly the same quantity of the acid solution, in the same proportion; and sealed one so as to exclude the contents completely from the atmosphere, and left the other exposed to the atmosphere. Under these opposite conditions, both, in the course of eight months, presented almost the same appearance, and no appreciable distinction could be recognized between their odours. There were no marks or signs of putrefaction in either.

The second class of experiments also gave the same result, and shows that only careful attention and regular application are required to produce always similar effects. I used the muslin cloth so as to allow a free current of air to all parts of the wounds. I firmly believe that the real difference in healing with or without suppuration is chiefly, if not altogether, owing to regularity in the application; and that the beneficial effects of the acid are to be principally attributed to its chemical and stimulating influence on the constituents of the blood and other parts concerned.—*British Medical Journal.*

THE ANTAGONISM BETWEEN THE ACTIONS OF PHYSOSTIGMA AND ATROPIA.*

In a Preliminary Note read before the Royal Society of Edinburgh on the 31st of May, 1869, a number of experiments were described, which proved that the lethal action of certain doses of physostigma can be prevented by the administration of atropia.† Further, it was pointed out, that antagonism between any two substances, in the sense of the lethal action of the one being preventible by the physiological action of the other, had not previously been shown to exist by any certain and satisfactory evidence. In the various instances where experiment seemed to indicate the existence of such an antagonism, sufficient proof was not given that the dose of the substance whose action appeared to be antagonized was certainly a lethal one. The conflicting opinions and doubts this fallacy has given origin to, have induced the author to follow a plan whereby it may be completely avoided.

In the first place, the minimum fatal dose of physostigma for the species of animal employed was accurately determined by a number of preliminary experiments; so that the weight of the animal being ascertained, it was an easy matter to be certain of the dose that could kill it. Then, in those experiments where an animal recovered after the administration of a dose of atropia given in combination with a dose of physostigma, equal to or in excess of the minimum fatal, it was killed many days afterwards, and when the effects of the two substances had completely disappeared, by a dose of physostigma, equal to or less than that from which it had previously recovered. Therefore, when the administration of atropia prevented an otherwise fatal dose of physostigma from causing death, a perfect demonstration was obtained of the power of atropia to produce some physiological action or actions that counteracted some otherwise lethal action or actions of physostigma.

In the preliminary note referred to, it was suggested that, as both atropia and physostigma are capable of producing a number of different actions, several of which may not be mutually antagonistic, and that, as both substances are capable of producing several actions of a similar kind, considerably less potent to cause death than those by which their fatal effects are usually induced, it would probably be found that a region exists where the non-antagonized and the similar actions are present in sufficient degrees of activity to be themselves able to produce fatal results. This anticipation has proved to be correct. A large number of experiments have been made, by which the region of the successful antagonism of fatal doses of physostigma has been defined with considerable exactness. The smallest and the largest doses of atropia that are able to prevent death after the administration of different fatal doses of physostigma, and the maximum fatal dose of physostigma that is capable of being rendered non-fatal by atropia were ascertained, and it was found that beyond these various points death may be produced by combined doses of the two substances, either by some non-antagonized action belonging to one or other of them, or by a combination of similar actions belonging to both.

As the above results could be obtained only by performing a very large number of experiments, rabbits were the animals selected, it being impossible to obtain a sufficient number of dogs, or other convenient animal. The weight of animal employed was, as nearly as possible, three pounds; and when below or in excess of this a correction was made, so that each dose represented three pounds weight of animal.

In one portion of this investigation, experiments were performed in which physostigma was given five minutes after atropia, both substances being injected under the skin. In the first series, the dose of physostigma was the minimum fatal, and the doses of atropia ranged from one that was too small to prevent the lethal action of this dose of physostigma, through a number of gradually increasing doses of atropia that were able to prevent death, until a dose was found whose administration resulted in death. Similar series of experiments were made with doses of physostigma, one and a half times, twice, two and a half times, thrice, and three and a half times as large as the minimum fatal. With the minimum fatal dose of physostigma, it was found that while ·01 grain of atropia is too small to prevent death, ·015 grain is able to do so; and that with any dose ranging from ·015 grain to 5·2 grains the lethal effect of this dose of physostigma may

* Abstract of a Paper read before the Royal Society of Edinburgh, May 29, 1871.

† June, 1871.—While this Abstract is passing through the press, the author has received a paper by M. Bourneville, in which the above result is satisfactorily confirmed by experiments on guinea-pigs.

be prevented; while if the dose of atropia be 5·3 grains or more, the region of successful antagonism is left, and death occurs. With one and a half times the minimum fatal dose of physostigma, successful antagonism was produced with doses of atropia ranging from ·02 grain to 4·2 grains: with twice the minimum fatal of physostigma, with doses of atropia ranging from ·025 grain to 3·2 grains; with two and a half times the minimum fatal of physostigma, with doses of atropia ranging from ·035 grain to 2·2 grains; with thrice the minimum fatal of physostigma, with doses of atropia ranging from ·06 grain to 1·2 grain; and with three and a half times the minimum fatal dose of physostigma, with doses of atropia ranging from ·1 grain to ·2 grain. Successful antagonism could not be obtained above this dose, and, accordingly, three and a half times the minimum fatal dose of physostigma would appear to be about the largest quantity whose lethal action may be prevented by administering atropia five minutes previously.

A similar series of experiments has been made, in which physostigma was administered five minutes before atropia, and the results were essentially the same, excepting that the region of successful antagonism was found to be more limited.

Series of experiments were also made, in each of which the doses of physostigma were the same, and the doses of atropia varied; while with each dose of atropia, several experiments were made which differed from each other by a difference in the interval of time between the administration of the two substances.

It seemed of interest to ascertain what dose of atropia is required to produce death with a dose of physostigma below the minimum fatal. The experiments performed for this purpose show that when one half of the minimum fatal dose of physostigma is given five minutes after atropia, so large a dose of the latter substance as 9·8 grains is required in order to cause death; recovery taking place with doses ranging from 3 to 9·5 grains.

The minimum fatal dose of sulphate of atropia given alone was found to be twenty-one grains for a rabbit weighing three pounds. It is, therefore, remarkable that the $\frac{3}{200}$ths of a grain can prevent a dose of physostigma, equal to the minimum fatal, from causing death, and that the $\frac{1}{10}$th of a grain is capable of rendering non-fatal a dose of physostigma, equal to three and a half times the minimum fatal.

Excepting dilatation of the pupils, these minute doses of atropia, and indeed any dose capable of antagonizing the lethal action of physostigma, are unable to produce any symptom recognizable by a mere inspection of the animal. Still, they undoubtedly produced energetic physiological effects—effects, however, which it is unnecessary to describe in this brief abstract. It is sufficient to point out that the notion, which exists in many quarters, that rabbits can scarcely be affected by atropia is an erroneous one.

Without referring to the other results obtained in his investigation, the author pointed out, in conclusion, that unless the antagonism between any two active substances be examined in the manner indicated in this communication, no satisfactory proof of its existence can be obtained. The superficial area of the region should always be defined, otherwise indications of antagonism obtained by one observer will be liable to be discredited by those who subsequently examine the subject. The first observer may succeed in performing an experiment within the area of successful antagonism, and thus feel satisfied of its existence; but his successors may fail in obtaining any proof by so varying the dose of one or other substance as to pass the limits of the region of success. Feeling assured that many examples of successful antagonism, besides the one he had the honour of bringing before the Society, will yet be discovered, the author could not avoid the conclusion that the imperfect methods of investigation hitherto pursued are accountable for the absence of success that has attended the numerous researches made on this subject—a subject, it need scarcely be added, of the greatest importance to toxicology and to scientific therapeutics.

THE GASEOUS AND LIQUID STATES OF MATTER.

BY THOMAS ANDREWS, M.D., F.R.S.,

Vice-President of Queen's College, Belfast.

(*Concluded from page* 145.)

At 32°·5 the fall, when liquefaction might be expected, is less abrupt than at 31°·1; and at 35°·5, although still manifest, it is further reduced. At 48°·1 the fall shown at lower temperatures can no longer be distinctly observed, and the curve representing the change of volume approximates to that of a perfect gas. There can be little, if any, doubt that at a higher temperature carbonic acid would behave under augmenting pressures nearly as nitrogen or hydrogen.*

I have frequently exposed carbonic acid, without making precise measurements, to much higher pressure than any of the foregoing, and have made it pass without break or interruption from what is regarded by every one as the gaseous state, to what is, in like manner, universally regarded as the liquid state. Take, for example, a given volume of carbonic acid gas at 50° C., or at a higher temperature, and expose it to increasing pressure till 150 atmospheres have been reached. In

---

* These different modes of passing from the gaseous to the liquid state are admirably illustrated by a solid model constructed by Prof. J. Thomson, which was exhibited at the lecture. I have been favoured by Prof. Thomson with the following description of this model:—

"The model combines Dr. Andrews' experimental results in a manner tending to show clearly their mutual correlation. It consists of a curved surface referred to three axes of rectangular co-ordinates, and formed so that the three co-ordinates of each point in the curved surface represent, for any given mass of carbonic acid, a pressure, a temperature and a volume, which can coexist in that mass.

"In Dr. Andrews' diagram of curves, published in his paper in the 'Transactions of the Royal Society for 1869,' p. 583, the experimental results, for each of several temperatures experimented on, are combined in the form of a plane curved line referred to two axes of rectangular co-ordinates. The curved surface in the model is obtained by placing these curved lines with their planes parallel to one another, and separated by intervals proportional to the differences of the temperatures to which the curves severally belong, and with the origins of co-ordinates of the curves situated in a straight line perpendicular to their planes, and with the axes of co-ordinates of all of them parallel in pairs to one another, and by cutting the curved surface out so as to pass through those curved lines smoothly or evenly.

"The curved surface so obtained exhibits in a very obvious way the remarkable phenomena of the voluminal conditions at and near the critical point of temperature and pressure in comparison with the voluminal conditions throughout other parts of the indefinite range of gradually-varying temperatures and pressures. This curved surface also helps to afford a clear view of the nature and meaning of the continuity of the liquid and gaseous states of matter. It does so by its own obvious continuity throughout the expanse to which it might be extended round the outside of the critical point in receding from the range of the points of pressure and temperature where an abrupt change of volume can occur by gasification or condensation. On the curved surface in the model, Dr. Andrews' curves for the temperatures 13°·1, 21°·5, 31°·1, 35°·5 and 48°·1 Centigrade, from which it was constructed, are shown drawn in their proper places. The model admits of easily exhibiting in due relation to one another a second set of curves in which each curve would be for a constant pressure, and in which the co-ordinates would represent temperatures and corresponding volumes. It serves generally as an aid towards bringing the whole subject clearly before the mind."

this process its volume will steadily diminish as the pressure augments, and no sudden diminution of volume, without the application of external pressure, will occur at any stage of it. When the full pressure has been applied, let the temperature be allowed to fall till the carbonic acid has reached the ordinary temperature of the atmosphere. During the whole of this operation no breach of continuity has occurred. It begins with a gas, and by a series of gradual changes, presenting nowhere any abrupt alteration of volume or sudden evolution of heat, it ends with a liquid. The closest observation fails to discover anywhere indications of a change of condition in the carbonic acid, or evidence, at any period of the process, of part of it being in one physical state and part in another. That the gas has actually changed into a liquid would, indeed, never have been suspected, had it not shown itself to be so changed by entering into ebullition on the removal of the pressure. For convenience, this process has been divided into two stages, the compression of the carbonic acid, and its subsequent cooling; but these operations might have been performed simultaneously, if care were taken so to arrange the application of the pressure and the rate of cooling, that the pressure should not be less than 76 atmospheres when the carbonic acid had cooled to 31°.

We are now prepared for the consideration of the following important question. What is the condition of carbonic acid when it passes, at temperatures above 31°, from the gaseous state down to the volume of the liquid, without giving evidence at any part of the process of liquefaction having occurred? Does it continue in the gaseous state, or does it liquefy, or have we to deal with a new condition of matter? If the experiment were made at 100°, or at a higher temperature, when all indications of a fall had disappeared, the probable answer which would be given to this question is that the gas preserves its gaseous condition during the compression; and few would hesitate to declare this statement to be true if the pressure were applied to such gases as hydrogen or nitrogen. On the other hand, when the experiment is made with carbonic acid at temperatures a little above 31°, the great fall which occurs at one period of the process would lead to the conjecture that liquefaction had actually taken place, although optical tests carefully applied failed at any time to discover the presence of a liquid in contact with a gas. But against this view it may be urged with great force, that the fact of additional pressure being always required for a further diminution of volume is opposed to the known laws which hold in the change of bodies from the gaseous to the liquid state. Besides, the higher the temperature at which the gas is compressed, the less the fall becomes, and at last it disappears.

The answer to the foregoing question, according to what appears to me to be the true interpretation of the experiments already described, is to be found in the close and intimate relations which subsist between the gaseous and liquid states of matter. The ordinary gaseous and ordinary liquid states are, in short, only widely separated forms of the same condition of matter, and may be made to pass into one another by a series of gradations so gentle that the passage shall nowhere present any interruption or breach of continuity. From carbonic acid as a perfect gas to carbonic acid as a perfect liquid, the transition we have seen may be accomplished by a continuous process, and the gas and liquid are only distant stages of a long series of continuous physical changes. Under certain conditions of temperature and pressure, carbonic acid finds itself, it is true, in what may be described as a state of instability, and suddenly passes, with evolution of heat, and without application of additional pressure or change of temperature, to the volume, which by the continuous process can only be reached through a long and circuitous route. In the abrupt change which here occurs, a marked difference is exhibited, while the process is going on, in the optical and other physical properties of the carbonic acid which has collapsed into the smaller volume, and of the carbonic acid not yet altered. There is no difficulty here, therefore, in distinguishing between the liquid and the gas. But in other cases the distinction cannot be made; and under many of the conditions I have described, it would be vain to attempt to assign carbonic acid to the liquid rather than the gaseous state. Carbonic acid, at the temperature of 35·5°, and under a pressure of 108 atmospheres, is reduced to $\frac{1}{430}$ of the volume it occupied under a pressure of one atmosphere; but if any one ask whether it is now in the gaseous or liquid state, the question does not, I believe, admit of a positive reply. Carbonic acid at 35·5°, and under 108 atmospheres of pressure, stands nearly midway between the gas and the liquid; and we have no valid grounds for assigning it to the one form of matter any more than to the other. The same observation would apply with even greater force to the state in which carbonic acid exists at higher temperatures and under greater pressures than those just mentioned. In short, the passage under great pressures from the liquid to the gaseous state may be effected by the application of heat without break or breach of continuity. That a marked change in the physical properties of the substance occurs during this process is no objection to its being continuous. If mercury as a liquid is opaque and as a gas is transparent, the red and translucent bromine, on the other hand, when heated above the critical point, becomes so opaque as almost to resemble a mass of resin. Frankland has shown that the flame of hydrogen becomes continuous when the gas is burned under a pressure of 20 atmospheres, and these experiments have been since extended by the same able chemist and Lockyer. We must not, however, suppose that one intermediate state exists between liquid and gas; on the contrary, an indefinite succession of intermediate states may truly be said to connect the liquid proper and the gas proper; in other words, the passage is continuous. When the critical point is attained, tho density of the liquid and gas becomes the same, and the tube is filled with homogeneous matter.

As regards the question of the continuity of the solid and liquid states, it would be necessary, in order to establish this continuity, to obtain, by the combined action of heat and pressure, the solid and liquid of the same density and of like physical properties. To accomplish this result will probably require pressures far beyond any which can be reached in transparent tubes; but it may be possible to show by experiment that the solid and liquid can be made to approach to the required conditions.

THE HONEY TRADE.

BY P. L. SIMMONDS.

The following facts connected with the honey trade, showing the great commercial importance of this product of the bee in various countries, are taken from the *Journal of Applied Science*.

Mr. Braithwaite Poole, some years ago, in his work on the 'Statistics of British Commerce,' estimated, after careful inquiries of the quantities transported over the kingdom (for which he had peculiar facilities), that the production of honey here amounted to 2000 tons, which he valued at £80,000. The annexed figures will give an idea of the foreign imports. The average of the four years ending 1858 was 3712 cwt., and the last three years for which we have official returns give the following:—

	Quantity. Cwt.	Value.
1867	5,663	£8,681
1868	6,674	10,077
1869	14,820	22,570

At the present day all the civilized countries of the globe produce honey, and give more or less attention to apiculture, according as the climate and vegetation are suited to the bees. The most recent statistics available give the following estimate of the number of hives, with the authority:—

	Number of hives.
France (Block's Statistics) . .	2,200,000
Austria	2,733,000
Prussia Proper (M. Wiebahn) .	761,284
Bavaria (Block)	202,923
Hanover (M. Wiebahn) . . .	230,689
Electoral Hesse (M. Wiebahn) .	40,000
Duchy of Nassau (Block) . . .	15,097
„ Baden „ . . .	75,111
Würtemberg	100,000
Oldenburg (Block)	45,000
Spain	758,788

The latest official statistics for France gave the total value of hives at 16½ million francs, or about 6*s*. per hive and its contents, but half of this may be set down for the hive and its protective supports, etc. The mean quantity of the honey produced yearly was stated at 6,670,000 kilogrammes, worth a little more than 5½ million francs. This would give about 6 lb. of honey for each hive. In 1863 the import of honey into France amounted to 185,797 kilogrammes, and the exports to 420,568 kilogrammes; in 1866 the imports were 259,500 kilogrammes, valued at 389,400 francs, and the exports 785,900 kilogrammes.

If a piece of fresh honeycomb, with its cells full of honey, be inverted on a dish, the pure honey will flow out, constituting virgin honey. If this be allowed to rest for some time, it will divide itself into two parts, the one consisting of a number of sphericles of a pale yellowish or almost whitish colour, and formed of a number of crystals radiating from the centre, and the other a white syrup. The crystalline sphericles are a true sugar, and in every sense identical with grape or fruit sugar, whilst the syrup contains the same sugar with a certain portion of wax, and very often, and indeed always, a quantity of sugar having the same composition as cane sugar, but in an uncrystallizable form. Gum and mannite, or manna sugar, have also been obtained, especially in the turpentine-like honey; but it is probable that they are products of decomposition, for they are not present in good honey; moreover, we know that under certain circumstances cane sugar is decomposed into mannite, gum and lactic acid, which is also usually present in honey whenever mannite has been noticed in it. The tendency of some honeys to a turpentine consistency appears to be intimately connected with the system of management of the bees, with the plants upon which they feed, and upon many other little understood causes.

Honey was used instead of sugar until the means of extracting that substance in quantity from the sugar-cane was found, and more recently its extensive fabrication from the beetroot. Honey is employed for food, for drink and for medicine; by mixing it with water and allowing it to ferment, hydromel is obtained, and honey wine, metheglin or mead, was long a popular beverage. By distillation alcohol is obtained. Honey is also employed in confectionery and pastry, for making gingerbread. In the fabrication of liquors it is used in sweetening Dantzic spirit, maraschino, rosoglio, etc. Real mead or metheglin is a fermented wine, but many drinks made from honey are little else than honey water or hydromel. Such is the sbitene of Russia, which consists of honey mixed with boiling water and boiling milk, and seasoned with pepper.

Raw honey varies in its properties according to the nature of the vegetation from which the bees have gathered their food; according as the honey is obtained from cultivated or wild bees: according to the method and attention used in separating it from the wax, as well as according to the age of the honey and the manner of preserving it. The preservation of honey is best effected in small wooden tubs with well-closed lids, so that such a vessel, when once opened, may be emptied in three or four months. The honey, after having run and been pressed out of the comb at a temperature of from 88° 25′ to 90° Fahrenheit, should be immediately poured into these vessels, which ought to be put away in a dry, cool spot. The honeys of different parts even of the same country will differ. Thus the honeys of Narbonne, England and Minorca can be distinguished by their flavours.

In France a good swarm of bees in two years will yield nearly 30 lb. of honey, and they are still more profitable in countries that are covered with flowers the greatest part of the year.

Honey is separated from the comb by dripping and by expression, and a still inferior kind is obtained by heating the comb before it is pressed. Virgin honey is that obtained from the young hives which have not swarmed. The two kinds of honey usually met with are the white and the yellow. The white trickles out spontaneously from the comb. The combs are broken soon after they are made, and laid upon hurdles or mats of osier, or on linen cloth, fastened at the four corners to as many posts, and then an excellent pure honey is obtained, which hardens in a short time. This is put into glazed earthen pots. The best French honey is that from the province of Languedoc, known in commerce as Narbonne honey. It should be new, thick, granulated, of a clear, transparent white colour. If it is very pure, it is almost as hard as sugar candy. The honey made in mountainous countries is more highly flavoured than that of low grounds; and that made in the spring is more highly esteemed than that gathered in the summer or autumn.

Yellow honey is obtained by pressure from all sorts of honeycombs, and even from those whence the virgin honey has been extracted. The combs are broken and heated with a little water in basins or pots, kept continually stirred. They are then put into bags of thin linen cloth, and placed in a press to squeeze out the honey. The wax remains in the bag, but some small portions will generally escape through the bag with the honey.

The colour of honey varies very considerably, according probably to the difference of the vegetation on which the insects feed. Sometimes it is of a green hue, sometimes it is black, blood red, and at others it offers various shades of orange or yellow, and there are instances on record of dysentery and death occasioned by the noxious qualities it contains. The island of Bourbon yields a delicate kind of green honey, which is exported to India and bears there a very high price. The same coloured honey occurs also in Southern Africa, and it is not improbable that in both localities the same species of bee will eventually be discovered to exist. At the island of Bulama, and in other places, there is a fly called the honey fly, which deposits its sweets in the hollows of trees, but the quantity is so trifling as scarcely to deserve notice. In the island of Madagascar, also, other species of flies are reported to produce honey. Honey is produced very abundantly in the island of Candia, and more so in the greater part of the islands of the Archipelago than almost anywhere else. The Sicilian honey is particularly high-flavoured, and in some parts of the island it is said even to surpass that of Minorca, which is no doubt attributable to the large quantity of aromatic plants which overspread the country. There the honey is gathered three times in the year; in July, August and October. It is found by the peasants in the hollows of trees and rocks. The country of the Upper Hybla is still, as formerly, the part of the island that is most celebrated for this article.

The Pharmaceutical Journal.

SATURDAY, AUGUST 26, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PHARMACOPŒIA COMMITTEE.

IN the columns of a recent impression we reported the Proceedings of the General Medical Council, with reference to its Pharmacopœia Committee. After the publication of the British Pharmacopœia of 1867, this committee was appointed to watch over the progress of pharmacy, and make such additions and corrections as would further facilitate hereafter the preparation of the next edition of the British Pharmacopœia. The sum of £50 annually was placed at its disposal by the Council. The general satisfaction given by the present edition induced the committee to retain Dr. REDWOOD's services, for the purpose of reporting to it all matters relevant to the subject, which might come under his notice. The work done by this committee does not appear to have given satisfaction to the Irish members of the Council,—there having been only one meeting of it during the last two years. Dr. AQUILLA SMITH seemed to feel ashamed of his position as one of its members; Dr. APJOHN objected to the committee being re-appointed, and proposed that the task of collecting information for the new edition be entirely entrusted to Dr. REDWOOD, but his motion did not find a seconder. We are glad that such was the case, and, although the motion implied such confidence in Dr. REDWOOD, and thus conferred an honour on English pharmacy, still there is a neutral ground on which the medical practitioner and pharmacist must meet in compiling a Pharmacopœia. Take, for example, remedies for external use,—a knowledge of therapeutics is required to adjust the strength of these and many other preparations. Dr. REDWOOD, we have no doubt, will do his best with the "villainous saltpetre," and "parmaceti," but we object to the Pharmacopœia committee shirking the responsibility which they, on their appointment, incurred. Their duties, as yet, have been light, because the Pharmacopœia, up to the date of its publication, was as perfect as such a work could be, but as time rolls on, pharmacy—a practical art—cannot remain quiescent. Improvements in manufacture, and new medicines must be noted.

On the Continent, the compilation of a universal Pharmacopœia has been broached more by the pharmacists than the medical practitioners. This for central Europe is a great desideratum; and so far as the German empire is concerned, uniformity will there be shortly attained by a *German Pharmacopœia*. We in our insular position may not feel the need of this uniformity so much as some of the minor German States, yet when reference to pharmaceutical preparations is made in foreign medical literature, the English reader is painfully embarrassed in trying to comprehend what is meant. In translations of such works published by the Cavendish Society, for example, the translators, to make the subject intelligible, have great difficulty in explaining by notes the composition of the pharmaceutical preparations mentioned in the text of the work. Pharmacists, both at home and abroad, have also a much greater difficulty in dispensing accurately foreign prescriptions, as these often bear no trace of the country in which they were written, or the Pharmacopœia to which they refer. Would not the Pharmacopœia Committee be fulfilling its functions by making overtures to the authorities of Continental nations to try to bring about such a uniformity as would be beneficial to all?

DR. GREENHOW'S REPORT ON THE EXAMINATIONS OF THE PHARMACEUTICAL SOCIETY CONDUCTED IN LONDON.

THE Thirteenth Report of the Medical Officer of the Privy Council has just been issued. It contains, in the Appendix, Dr. GREENHOW's Report on the Examination of the Pharmaceutical Society conducted in London. This Report is of considerable interest, as in it Dr. GREENHOW describes the methods adopted in the various examinations, and gives the opinion which he, as the medical officer attending on behalf of the Privy Council, has formed, respecting the standard adopted in each examination, and the manner in which the examiners perform their duties. We, therefore, print it entire:—

"During the year 1870 the Board of Examiners of the Pharmaceutical Society held 26 meetings: four for the Preliminary Examination in Latin, English, and arithmetic, and 22 for the technical examinations.

"At the Preliminary Examinations 742 candidates presented themselves, of whom 521 passed, and became thereby qualified to present themselves for the Minor Examination, whilst the remaining 221 were rejected. I have carefully read the papers set for these examinations, and also many of the answers written both by successful and unsuccessful candidates, and am of opinion that the examination is not too severe nor the mode of conducting it too rigid, and that the value of the written answers has been estimated with accuracy and impartiality. In these circumstances, the rejection of so large a proportion of the candidates, on the score of defective attainments in the main subjects of middle-class instruction, indicates the low standard of general education prevalent among those classes of society from which the candidates are chiefly derived; and renders it obvious that, until some improvement takes place in this respect, the standard of preliminary examination by the Pharmaceutical Society is pitched as high as can be attempted with practical advantage.

"Of the 22 meetings held for the examination of candidates in technical subjects, 13 were devoted to the Major and Minor Examinations and 9 to the Modified Examination.

"During the year 1870, 258 candidates presented themselves for the *minor* examination, of whom 178 passed and were registered as chemists and druggists, and 80, or nearly one-third, were rejected as incompetent. Of these 80 unsuccessful candidates 50 failed to obtain the number of marks requisite for passing the examination as a whole; the remaining 30 obtained the requisite total number of marks calculated on all the subjects collectively, but failed to obtain the numbers requisite for passing in all the separate subjects. Of these 30 candidates, 7 failed in one of the six subjects comprised in the examination, 18 in two, 4 in three, and 1 in four subjects respectively, and by the regulations of the Pharmaceutical Society they must present themselves for re-examination in those separate subjects in which they failed to pass, before they can become qualified for registration as chemists and druggists.

"I should, perhaps, briefly repeat here what I explained in my report of last year, that in order to pass any of the examinations a candidate must obtain not less than half the number of marks given for the examination as a whole, and is even then only entitled to pass provided that in none of the separate subjects comprised in the examination his number of marks has fallen below one-fourth of the standard number allotted to the subject. It is true that even though a candidate may have failed to obtain one-fourth of the standard number of marks in a single subject, if his excellence in all the other subjects be remarkable he may still possibly be allowed to pass by a special vote of the Board of Examiners; but practically such a case very rarely occurs. Further, a candidate who has obtained the required total number of marks calculated on all the subjects of examination collectively, but has fallen below one-fourth of the standard number in one or more of the separate subjects, is required to present himself for re-examination, not only in those subjects, but also in any of the other subjects in which he may have failed to obtain one-half of the standard number of marks. By these arrangements, which appear to me to be equitable, superior excellence in some branches of the examination is to a certain degree set against any weakness in others which does not involve incompetence in essentials.

"For the *major* examination 75 candidates presented themselves during the year, of whom 59 passed and were registered as pharmaceutical chemists, whilst 16, or more than one-fifth, were rejected. Nor can this be regarded as otherwise than a large proportion, when it is considered that all these candidates must have previously passed the minor examination, and were thereby already qualified to carry on business as chemists and druggists. The examination of candidates for the major qualification is conducted partly by means of written papers; partly by *vivâ voce* questions and answers upon the nature, quality, composition and preparation of drugs and chemicals placed before the candidates; and partly by practical examination in the dispensing and compounding of prescriptions, and in the application of the requisite chemical tests for determining the nature of one or more of the definite chemical compounds employed in medicine. The papers written in answer to questions set by the examiners show that the candidates have received very different degrees of elementary and technical education. Some of the papers evince a really high degree of cultivation, whilst others fall below mediocrity. The practical examination in testing is conducted on the same day as the written examination, and each candidate is required to determine, by means of the appropriate chemical tests, the presence, in a given solution, of some chemical comprised in the British Pharmacopœia. The candidate is not made aware until the moment what solution will be presented to him for examination, and he applies his tests under the eye of the examiner, who takes each candidate in turn at a counter upon which are placed the requisite apparatus and tests. Solutions of such salts as the perchloride of mercury, sulphate of copper, perchloride of iron, bromide of potassium, acetate of lead and alum were given to be tested on the occasions on which I was present. Of the sixteen candidates who were unsuccessful in the major examination, thirteen failed to obtain the number of marks necessary in order to pass the examination as a whole; the remaining three obtained the requisite total calculated on all the subjects collectively, but fell below the standard minimum of marks in one or more of the separate subjects, and will, therefore, be required to undergo a re-examination in those subjects before they can be registered as pharmaceutical chemists.

"The *modified* examination was instituted, as I explained last year, for the benefit of such persons as, being of full age, had been actually engaged in the dispensing and compounding of prescriptions as assistants to pharmaceutical chemists, or to chemists and druggists, for a term of not less than three years previous to the passing of the Pharmacy Act of 1868.

"The modified examination entitles such candidates, if they can give proof of reasonable practical competence, to be registered as chemists and druggists without having attained the standard of scientific knowledge now fixed for the minor examination which confers the same title. It will therefore be discontinued so soon as the class of persons for whose benefit it was instituted shall have all been examined. During the past year 348 candidates presented themselves for this examination, of whom 231 passed and were registered as chemists and druggists, and 117 were rejected. Of these latter, 102 failed to obtain the number of marks required to enable them to pass the examination as a whole; the remaining 15 obtained the total number, but failed to obtain the required minimum in one or more of the separate subjects. Two of the 15 failed in two subjects and 13 in one subject each; but the four subjects which alone are comprised in this examination are all so indispensable, that incompetence in any one of them would render a person quite unfit to be trusted with the responsible duty of compounding and dispensing prescriptions. The candidates in these modified examinations have appeared to me to be treated by the examiners with equal consideration and tact, so that while on the one hand they are not rejected on matters of minor importance or technical form, on the other hand they are not passed unless their practical competence be proved sufficient to guarantee the safety of the public. The fact, therefore, of the rejection of fully one-third of the whole number of candidates, affords conclusive evidence of the danger to which the public must have been exposed, by the employment of so large a proportion of unskilled persons as assistants in the business of selling drugs and compounding prescriptions, previously to the passing of the Pharmacy Act.

"During the year 1870, I was present at the pharmaceutical examinations on thirteen occasions, namely, on January 7th and 19th, on February 16th, April 20th, May 6th and 25th, July 1st and 13th, October 19th and 20th, and on December 2nd, 21st, and 23rd. Four of these were modified examinations, and the remaining nine major and minor examinations.

"No change requiring mention has been made during the past year in the mode of conducting any of the examinations, but I observe some minor improvements in method, and I am led to believe that it is the intention of the Board of Examiners gradually to raise the standards of competence, both for the minor and major examinations. I have no suggestions to offer on this head, with reference either to the minor or the modified examination, both of which appear to me to be as high as could be enforced with advantage at the present moment. But with reference to the major examination I would venture to suggest that, as the candidates for this examination are already qualified to carry on business as chemists and druggists, there would be no hardship in fixing the standard for passing it somewhat higher; thus making a greater difference than now exists between the grade of chemist and druggist and that of pharmaceutical chemist, and ensuring in those who bear the latter title a higher degree of pharmaceutical skill. I am of opinion further that, inasmuch as the increase of practical pharmaceutical skill is what will most conduce to the service of the public, the standard of the major examination should be heightened principally in its practical aspects, and that especially a profounder acquaintance with practical chemistry, and a more thorough grammatical knowledge of Latin should be required. With this view I would recommend that candidates for this examination should be required to estimate practically, by means of the volumetric test solutions appended to the British Pharmacopœia, the strength of such officinal preparations as are directed to be so estimated, and also to show considerable proficiency in reading difficult or unusual prescriptions written in the Latin language. I have, indeed, reason to believe that it is the intention of the Board of Examiners to carry out these improvements as they shall find practicable, but I hope that this expression of opinion on my part may strengthen their hands, and assist them to realize their intentions more speedily.

"In conclusion, I have much satisfaction in being able to report that the examinations of the Pharmaceutical Society, as conducted during the past year, afford a sufficient guarantee for the competence of persons admitted during that period to registration under the Pharmacy Act of 1868."

REPORT OF THE COMMISSIONERS OF INLAND REVENUE.

The Fourteenth Report of the Commissioners of her Majesty's Inland Revenue has been issued, giving the returns for the years ending 31st March, 1870–1871.

The quantity of spirit methylated during the year ending 31st March, 1870, was 977,469 gallons, being an increase of 91,510 gallons on the previous year. There has been again a small increase in the quantity during the present year, but not to such an extent as to call for any special remark.

The Commissioners call attention to an experiment made by a large landed proprietor of distilling spirit from beetroot grown in this country. In 1869, 350 acres were planted, and of the produce about 3500 tons of one produce was reserved for distillation. In consequence of the machinery being incomplete, the work was not commenced until January. The delay prevented the completion of the operation before the middle of April, by which time the beet was much injured by frost, spring growth, and storing, so that less extract and alcoholic product was obtained than in the earlier part of the year,—the quantity of spirit obtained in April being five per cent. less than in January. The total produce of spirits was 39,569 proof gallons, the average quantity per ton of beet being about 11 proof gallons. The quality of the spirit was superior to that usually obtained from beetroot.

During the year 1870–71 this distillery has been worked on a more extensive scale, but further experience is necessary before the experiment can be said to establish the success of beetroot distillation in this country.

In the Report, by the Principal of the Laboratory in connection with the department, the result is recorded of an investigation made to determine the proportion of essential oils in perfumed spirits as imported and their effect upon the bulk and strength of the alcohol present. For a considerable time back urgent representations had, from time to time, been made by English wholesale perfumers, to the effect that their trade was materially injured by the admission of foreign perfumed spirits into this country at a uniform duty of 14*s.* per bulk gallon, as such spirits were frequently of as high a strength as 60·0 o.p. On the other hand, it was contended that the essential oils largely contributed to the bulk of such spirits, and also that they interfered with the action of the hydrometer by showing the perfumed spirits to contain more alcohol than was actually present, and that therefore it would be unjust to charge them as ordinary spirits; it was also maintained that the various descriptions of perfumed spirits imported varied considerably in strength, and that 14*s.* per bulk gallon was a fair average charge. On the question being referred to this department, a method was devised of effectually separating and measuring the essential oils present in the perfumed spirits, and it was found that their effect upon the bulk of such spirits was comparatively small, and also that the hydrometer was scarcely affected by their presence. The experiments thus showed that English perfumers were in many cases subjected to unfair competition with their foreign rivals.

The number of samples of home-made glucose examined have been 321, representing 25,737 cwts., as against 199 samples and 16,676 cwts. in the previous year. Glucose imported from the Continent also shows a large increase, the number of samples having been 390 as compared with 222 in 1868.

Of tobacco 152 samples have been examined; 28 contained adulterants such as sugar, liquorice, and logwood. In one case the sample was adulterated with 30 per cent. of liquorice. The amount of tobacco cleared for consumption during the year 1869 gave an average of 1 lb. 5¾ oz. per head of the population, against 13¾ oz. in 1841. Adulterated samples of snuff have been found to contain oxide of iron, alumina, glass, coal, pinewood, fustic, straw, and an excessive amount of sand.

Sixty-three samples of coffee have been examined during the year, of which 32 were genuine; 30 were adulterated with roasted locust beans to an extent varying from ten to thirty per cent., and one with a vegetable substance that could not be identified. It having been ascertained that the whole of these adulterated samples had been manufactured by a wholesale firm in London upon unentered premises, the firm was prosecuted and a conviction obtained.

The difference in price between methylated spirit and pure spirit of wine is so great that it need occasion no surprise if a few instances are now and then discovered of the illegal substitution of the former for the latter. During the past year eight samples of medicines for internal use were found to have been prepared from methylated spirit. They comprised sweet spirits of nitre, paregoric, and the tinctures of catechu, rhubarb, and cardamoms.

Three samples sold as "Finish" have been found to consist of methylated spirit only. One of the samples was deeply coloured with aniline red dye, and had been illegally supplied in that state to a firm of colour-makers who wished to use methylated spirit for the purpose of trade without being subject to the usual regulations.

The number of samples of wood spirit examined for methylating purposes has been 326—the largest number hitherto received in any one year. Two of the samples were found to contain an admixture of ethylic alcohol to the extent of 10 and 45 per cent. respectively. Both were from the same methylated spirit-maker, against whom proceedings were taken, and the full penalties of the law recovered.

During the year 635 samples of lime- and lemon-juice, and 100 samples of spirits for fortifying the same, have been examined. Eighty of the former, and seven of the latter were recommended for rejection. For the first three months of the year, viz., from April 1st to June 30th, inclusive, samples of lime- and lemon-juice and spirits from the Port of London only were examined in this department, but from July 1st samples have, in addition, been received from the whole of the outports in the United Kingdom. Since the month of December last, by order of the Board of Trade, it has been optional on the part of the merchant whether he would have his spirits examined by the customs at the port where bonded, or at this laboratory.

In addition to the foregoing, upwards of eleven hundred samples of miscellaneous substances have been examined, including sugar, soap, pyroligneous acid, various wines, beers, and liqueurs, perfumed spirits, gin, Bay rum, sweet spirits of nitre, ether, beet syrup, etc.

We continue to receive satisfactory accounts of the cultivation of the cinchonas from nearly all parts of the world where they have been introduced. The East Indian cultivation is, perhaps, the most important; the plantations in Sikkim Himalaya, on the Neilgherry Hills, the Khasia Mountains, and also in Ceylon, are now established facts, and have begun to yield bark, which has found its way into the English market; that produced in the hill districts of India realizing a price equal to the produce of South America. Dr. Hooker in his annual report says that a ton of prepared bark has been sent to London from Ceylon, the produce of seeds sent to Dr. Thwaites from Kew in 1861. The late Dr. Thomas Anderson, to whom much credit is due for the successful introduction and cultivation of the plant in Sikkim, told us shortly before his death that ere long the produce of the Sikkim plantations would be so large that the bark might be disposed of at the rate of 3*d.* per lb.

In Jamaica forty acres of land were planted with cinchonas in 1868; about 40,000 plants occupying this extent of ground, all of which are healthy, their average height being from two to three feet. At the present time about 90 acres are under cinchona cultivation; and at the end of the present year it is expected that there will be 220 acres so occupied with about 200,000 plants. From St. Helena we also learn that the plants are not only thriving, and thus proving that they are perfectly satisfied with the soil and climate of their new island home, but that the plantations are being extended, and that everything connected with the cinchonas is progressing most satisfactorily.

We learn from some recently-published statistics of the University of Edinburgh Botanical Class, that in the session of 1871 the number of pupils was 306. Of these, 241 (including 5 ladies) were medical students, 12 pharmaceutical students and 53 general students.

Mr. J. B. Owen, of Louisville, Kentucky, reports in the *American Journal of Pharmacy*, that he has examined four specimens of subnitrate of bismuth taken from the American market. He found a trace of arsenic in one of the samples, and silver as a chloride was present in three, in one instance to the extent of ·37 per cent.

A nostrum extensively advertised in Philadelphia and its vicinity as an infallible remedy for epilepsy, upon examination appeared to consist of about fifteen grains of bromide of potassium, disguised by the addition of about five grains of powdered gentian root.

The appointments under the Act for regulating pharmacy in the city of New York* have been made by the Mayor. The gentlemen appointed are Mr. William Graham, superintendent of one of the stores of Messrs. Hegeman and Co., Mr. Frohwein, a graduate and one of the officers of the New York College of Pharmacy, Dr. Doremus, formerly professor of chemistry in the same college, and Dr. O'Leary.

* See Vol. I. p. 890.

Proceedings of Scientific Societies.

SOCIÉTÉ DE PHARMACIE DE PARIS.

At the Meeting of this Society, held on the 7th of June, under the presidency of M. St. Martin, Messrs. Sandford, Evans and Hills, of the Pharmaceutical Society of Great Britain, were unanimously elected corresponding members.

M. Méhu presented a specimen of cotton containing about one-tenth of its weight of iodine. This preparation gives off the iodine in the open air, but is easily preserved in well-stoppered bottles. It is prepared by heating the cotton in a water-bath with powdered iodine. If the proportion of the iodine be increased the fibre of the cotton is destroyed, and it becomes pulverulent.

M. Méhu also presented to the Society two specimens of colouring matter obtained from the urine of a patient suffering from albuminuria and diabetes, the one violet-red and the other blue, approaching to indigotin. They had been extracted from the urine, even when putrid, by the simple use of solvents, such as water, alcohol, ether and chloroform.

Dr. Calvert, who was present, said that in England a distinguished chemist, Schunck, had noticed in urine a colourless principle, indican, which becomes blue by exposure to the air, and is susceptible of yielding by decomposition glucose and indigotin.

M. Roucher said that he had obtained the two colouring matters from urine by following the directions of the German chemists. He thought the blue principle differed from indigotin only in its crystalline form, and added that indican resisted putrefaction energetically.

Dr. Calvert made some remarks on disinfectants, in the course of which he said that chloride of lime exercised a rapid but limited action. Thus, in nitrogenous organic matter disinfected by this substance, the putrefaction would recommence after a few days, even while the odour of the chloride of lime was still perceptible.

Dr. De Vrij gave some of the results of his researches upon the cinchona alkaloids.

M. Bourgoin stated that in an investigation of phthalic acid, made with the object of preparing phenylene, he had found that acid to comport itself in a similar manner to the most stable aromatic acids, such as benzoic and camphoric, and that it yielded no trace of phenylene even when placed in conditions the most varied.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

(*Continued from page* 153.)

Section B.—Chemical Science.

After the President's address, the reading of papers was commenced by Mr. Dewar reading a preliminary report on the "Thermal Equivalent of the Oxides of Chlorine." This was succeeded by a paper by Dr. Gladstone and Mr. Alfred Tribe, on "Some Experiments on Chemical Dynamics." In the discussion that followed the reading of this paper, some curious facts were mentioned with respect to the action of sugar on metallic iron. It is well known that it has not hitherto been possible, on account of this action to convey sugar in iron ships; but Dr. Calvert stated that he had discovered a very simple method which entirely prevented the action, and he had no doubt that henceforward sugar would be as safely carried in iron ships as in wooden bottoms.

A paper on the "Recent Progress of Chemistry in the United States" by Professor Wheeler, of Chicago, commenced the next day's proceedings; Mr. Henry Deacon gave an account of his "Chlorine Process as applied to the Manufacture of Bleaching Powder on the larger Scale," and a note on "Regianic Acid," a product derived from walnuts, was communicated by Dr. Phipson.

This was followed by a paper by Dr. Calvert on the "Estimation of Sulphur in Coal and Coke." The sulphur found in coal or coke often exists in two states, partly as sulphuric acid combined with lime, and partly as sulphur combined with iron; it is only the latter combination which lessens the commercial value of the fuel. By boiling the powdered coal with a solution of carbonate of soda, the lime composed is decomposed, and by washing the sulphuric acid may be removed; in the residue is contained the sulphur, combined with iron, which is estimated by any of the methods familiar to chemists.

An account of "Some Improvements in Chlorimetry" was given by Mr. I. Smyth. In his opinion the use of the milky solution of bleaching powder as employed in the usual methods of chlorimetry is unsatisfactory, and he accordingly recommends that the chloride of lime be decomposed by a solution of carbonate of soda and filtered from the precipitated carbonate of lime when the amount of available chlorine may be determined in the filtrate by any of the usual methods.

Professor Delffs, of Heidelberg, exhibited some splendid Crystals of Sorbin. This body was discovered nearly twenty years ago by Pelouze, but hitherto nobody has succeeded in preparing it from the source indicated by the distinguished French chemist. Dr. Delffs attributed the want of success to the fact that it was usual to combine the preparation of malic acid with that of sorbin, and he showed that it is only when the production of the former substance is dispensed with that sorbin is obtained. By strictly following the method given by Pelouze, Dr. Delffs obtained a large quantity of fine crystals of sorbin, but on searching for malic acid in the residue, he found that not a trace was present. He attributes its absence to its combination with the radical of alcohol (the malic acid being contained in the alcoholic extract of the berries of *Sorbus Aucuparia*, the source of the body), whereby malate of ethyl is formed, while by assimilating two atoms of water is converted into sorbin. It would appear therefore that no sorbin is contained ready formed in the fruit of *Sorbus Aucuparia*.

Dr. Moffat read a paper on "Ozonometry," in which he stated that ozone test papers do not become permanently coloured in the neighbourhood of cesspools, and that the brown coloration when found is removed by the products of putrefaction. He also stated that light, the humidity of the atmosphere, and the direction of the wind, influence the colouring of the test-paper, moisture with heat accelerating chemical action, while strong wind causes a great quantity of ozone to impinge upon the test-paper in a given time. To counteract the effects of these, he recommended the test-paper to be kept in a box. He next described a tube ozonometer which he had had in use, and gave results obtained by an aspirator ozonometer, and concluded by stating that the results obtained by the aspirator ozonometer were not satisfactory.

On Monday the proceedings commenced with two short papers by the President, Dr. Andrews, "On the Dichroism of the Vapour of Iodine," and "On the Action of Heat on Bromine." The fine purple colour of the vapour of iodine arises from its transmitting freely the red and blue rays of the spectrum, while it absorbs nearly the whole of the green rays. The transmitted light passes freely through a red copper or a blue cobalt glass. But if the iodine vapour be sufficiently dense, the whole of the red rays are absorbed, and the transmitted rays are of a pure blue colour. They are now freely transmitted as before by the cobalt glass, but will not pass through the red glass. The solution of iodine in bisulphide of carbon exhibits a similar dichroism, and according to its density appears either purple or blue when white light is transmitted through it. The alcoholic solution, on the contrary, is of a red colour, and does not exhibit any dichroism. If a fine tube be filled one-half with liquid bromine and one-half with vapour of bromine, and, after being hermetically sealed, be gradually heated until the temperature is above the critical point, the whole of the bromine becomes quite opaque, and the tube has the aspect of being filled with a dark red and opaque resin. A measure of the change of power of transmitting light in this case may be obtained by varying the proportion of liquid and vapour in the tube. Even liquid bromine transmits much less light when heated strongly in a hermetically-sealed tube than in its ordinary state. In connection with this subject, Mr. Dewar exhibited an experiment illustrating the action of light upon peroxide of chlorine.

The Report on the Utilization of Sewage was presented by Mr. Grantham. It was divided under the following heads:—(1.) Experiments on Britton's Farm, Mr. Hope. (2.) Comparison of Results during Winter of Croydon, Norwood and Britton's Farm Experiments, Dr. Corfield. (3.) Report on Analysis in connection with above, Dr. Corfield. (4.) Upward Filtration of Sewage at Ely, Dr. Corfield. (5.) Phosphate Process, Dr. Corfield. (6.) Dry Earth System at Lancaster, Drs. Corfield and Gilbert.

Dr. Bischof read a paper "On the Examination of Water for Sanitary Purposes," in which he sought to show that the appearance of the residue obtained by evaporation, when seen under the microscope, afforded a ready method of detecting sewage contamination.

Among other communications to this section were papers on the "Chemical Constitution of Glycollic Acid and its Heterologues, as viewed in the Light of the Type-nucleus Theory," by Dr. Otto Richter; on the "Constitution of some of the Oxychlorides of Vanadium discovered by Roscoe," by Dr. Thorpe; on the "Dissociation of Molecules by Heat," by Mr. Tichborne; on the "Rate of Action of Caustic Soda on a Watery Solution of Chloracetic Acid," by Mr. J. G. Buchan; "Some Remarks on the Proximate Analysis of Saccharine Matters," by Professor Apjohn; on a "Method of Preserving Food by Muriatic Acid," by the Rev. H. Highton; on the "Constitution of Salts," by Mr. Wanklyn; and a "Method of Testing Wood Naphtha," by Mr. Harkness.

On Saturday, August 5, the section visited the works of Young's Paraffin Light and Mineral Oil Company at Addriwell, West Calder. The visitors were conducted over the works and the various processes were explained by Dr. Playfair, M.P., after which they sat down to a luncheon, Mr. Young in the chair. In proposing the health of Mr. Young, Dr. Playfair said that some idea of the magnitude of the company's operations might be formed from the fact that its sales amounted to upwards of £1000 per day.

Section D.—Biology.

The opening address of this section was delivered by its President, Professor Allen Thomson. After a few preliminary remarks he said that the general title under which this section had met since 1866, viz. Biology, seemed to be advantageous, both from its convenience and as tending to promote the great consolidation of the science, and a juster appreciation of the relation of its several parts. It might be that, looking merely to the derivation of the term, it was strictly more nearly synonymous with physiology in the sense in which that word has been for a long time employed, and therefore designating the science of life, rather than the description of the living beings in which it is manifested. But until a better or more comprehensive term be found, that of biology might be accepted under the general definition of "the science of life and of living beings," or as comprehending the history of the whole range of organic nature,—vegetable as well as animal.

He then gave a short sketch of the history of the section and of its division into subsections. He pointed out that although the great development of the knowledge of biology seemed to necessitate the increase of subdivision of labour, it was incumbent on all who were desirous of promoting the advance of biological knowledge, to combat the confined views which are apt to be engendered by the too great restriction of study to one department, and to secure at first, by a wider study of the general principles and some of the details of collateral branches of knowledge, that power of justly comparing and correlating facts which will mature the judgment and exclude partial views. After some remarks upon the subjects of anthropology, histology and embryology, Professor Thomson next treated of organic chemistry and vital force, as follows:—

The consideration of the finest discoverable structures of the organized parts of living bodies is intimately bound up with that of their chemical composition and properties. The progress which has been made in organic chemistry belongs not only to the knowledge of the composition of the constituents of organized bodies, but also to the manner in which that composition is chemically viewed. Its peculiar feature, especially as related to biological investigation, consists in the results of the introduction of the synthetic method of research, which has enabled the chemist to imitate or to form artificially a greater and greater number of the organic compounds. In 1828 the first of these substances was formed by Wöhler, by a synthetic process, as cyanate of ammonia, or urea. But still, at that time, though a few no doubt entertained juster views, the opinion generally prevailed among chemists and physiologists that there was some great and fundamental difference in the chemical phenomena and laws of organic and inorganic nature. Now, however, this supposed barrier has been in a great measure broken down and removed, and chemists, with almost one accord, regard the laws of combination of the elements as essentially the same in both classes of bodies, whatever differences may exist in actual composition, or in the reactions of organic bodies in the more complex and often obscure conditions of vitality, as compared with the simpler, and, on the whole, better-known phenomena of a chemical nature observed in the mineral kingdom. Thus, by the synthetic method, there have been formed among the simpler organic compounds a great number of alcohols, hydrocarbons and fatty acids. But the most remarkable example of the synthetic formation of an organic compound is that of the alkaloid conia, as recently obtained by Hugo Schiff by certain reactions from butyric aldehyd, itself an artificial product. The substance so formed, and its compounds, possess all the properties of the natural conia,—chemical, physical, and physiological,—being equally poisonous with it. The colouring-matter of madder, or alizarine, is another organic compound which has been formed by artificial processes. It is true that the organized or containing solid, either of vegetable or animal bodies, has not as yet yielded to the ingenuity of chemical artifice; nor, indeed, is the actual composition of one of the most important of these, albumen and its allies, fully known. But as chemists have only recently begun to discover the track by which they may be led to the synthesis of organic compounds, it is warrantable to hope that ere long cellulose and lignine may be formed; and, great as the difficulties with regard to the albuminoid compounds may at present appear, the synthetic formation of these is by no means to be despaired of, but, on the contrary, may with confidence be expected to crown their efforts. From all recent research, therefore, it appears to result that the general nature of the properties belonging to the products of animal and vegetable life, can no longer be regarded as different from those of minerals, in so far at least as they are the subject of chemical and physical investigation. The union of elements and their separation, whether occurring in an animal, a vegetable, or a mineral body, must be looked upon as dependent on innate powers or properties belonging to the elements themselves; and the phenomena of change of composition of organic bodies occurring in the living state are not the less chemical because they are different from those observed in inorganic nature. All chemical actions are liable to vary according to the conditions in which they occur, and many instances might be adduced of most remarkable variations of this kind, observed in the chemistry of dead bodies from very slight changes of electrical, calorific, mechanical and other conditions. But because the conditions of action or change are infinitely more complex and far less known in living bodies, it is not necessary to look upon the phenomena as essentially of a different kind, to have recourse to the hypothesis of vital affinities, and still less to shelter ourselves under the slim curtain of ignorance implied in the explanation of the most varied chemical changes by the influence of a vital principle.

Zoology and botany were the next subjects in the order of discussion, and were followed by some remarks on the teaching of natural science in schools. The speaker expressed his opinion that the introduction of instruction in natural science into the primary schools was feasible, and said that a mind which is entirely without scientific culture is but half prepared for the common purposes of modern life, and is entirely unqualified for forming an opinion upon some of the most difficult and yet most common and important questions of the day, affecting the interests of the whole community.

In conclusion, Professor Thomson adverted to the subject of spiritualism, an aspect in which he said it might be thought that the appreciation of biological science has taken a retrograde rather than an advanced position. In this he did not mean to refer to the special cultivators of biology in its scientific acceptation, but to the fact that there appears to have taken place of late a considerable increase in the number of persons who believe, or who imagine that they believe, in the class of phenomena which are now called spiritual, but which have been known since the exhibitions of Mesmer, and indeed, long before his time, under the most varied forms, as liable to occur in persons of an imaginative turn of mind and peculiar nervous susceptibility. He admitted that extremely curious and rare, and to those who are not acquainted with nervous phenomena, apparently marvellous phenomena, present themselves in peculiar states of the nervous system,—some of which states may be induced through the mind, and may be made more and more liable to recur, and are greatly exaggerated by frequent repetition. But making the fullest allowance for all these conditions, it is still surprising that persons, otherwise appearing to be within the bounds of sanity, should entertain a confirmed belief in the possibility of phenomena, which, while they are at variance with the best established physical laws, have never been brought under proof by the evidences of the senses, and are opposed to the dictates of sound judgment. He denied the truth of the assertion that scientific men have neglected or declined to investigate the phenomena with attention and candour. From time to time men of eminence, and fully competent, by their knowledge of biological phenomena, and their skill and accuracy in conducting scientific investigation, have made the most patient and careful examination of the evidence placed before them by the professional believers and practitioners of so-called magnetic, phreno-magnetic, electro-biological and spiritualistic phenomena; and the result has been uniformly the same in all cases, when they were permitted to secure conditions by which the reality of the phenomena, or the justice of their interpretation, could be tested,—viz., either that the experiments signally failed to educe the results professed, or that the experimenters were detected in the most shameless and determined impostures. The phenomena are in great part dependent upon natural principles of the human mind, placed, as it would appear, in dangerous alliance with certain tendencies of the nervous system. They ought not to be worked upon without the greatest caution, and they can only be fully understood by the accomplished physiologist who is also conversant with healthy and morbid psychology. The experience of the last hundred years tends to show that while there are always to be found persons peculiarly liable to exhibit the phenomena in question, there will also exist a certain number of minds prone to adopt a belief in the marvellous and striking in preference to that which is easily understood and patent to the senses; but it may be confidently expected that the diffusion of a fuller and more accurate knowledge of vital phenomena among the non-scientific classes of the community may lead to a juster appreciation of the phenomena in question, and a reduction of the number among them who are believers in scientific impossibilities.

Dr. B. W. Richardson read the ninth of a series of reports "On the Physiological Action of Organic Chemical Compounds." The series was commenced at Newcastle in 1863. The substances described in the present report were chloral hydrate, anhydrous chloral, metachloral, bromal hydrate, nitrite of amyl, nitrate of ethyl, sulpho-urea, and hydride of amyl, called briefly hydramyl. He considered the question of what was a dangerous, and what a fatal dose of chloral hydrate, fixing the maximum dose at 140 grains. He stated that, in instances where chloral hydrate was producing dangerous symptoms, threatening to be fatal, warmth, food and artificial respiration were the great remedies; and he explained the dangers that were arising in the community from the practice of taking chloral hydrate as a narcotic luxury, like alcohol or opium. He strongly warned people against this practice, and stated that the *habitué* to this influence became a diseased person, and sometimes an unintentional suicide. Of nitrite of amyl the author mainly tried to show the action on the lungs; it caused paralysis of the blood-vessels, and produced congestion, and in the lungs changes were brought about analogous to some of those attending pulmonary consumption in the human subject. On the other hand, it produced a curative effect in certain diseases. The last substance named was chlor-hydramyl, a light, volatile fluid, intended to produce rapid insensibility to pain in short operations.—A brief discussion followed, in which Drs. Donkin, Marcet, Sharpey and Brunton took part.

Professor Balfour submitted some observations on the cultivation of ipecacuanha in the Edinburgh Botanical Gardens for transmission to India. A short time ago Mr. James M'Nab, of the Botanical Gardens, had discovered that by cutting the root of the plant under the ground surface, numerous new shoots could be got, and the plant so propagated much more easily and plentifully. They had thus been able to send out a number of healthy plants to India, which it was hoped would be there equally successfully cultivated.

Parliamentary and Law Proceedings.

Action against a Medical Practitioner for Negligence.

TROTTER v. DOWNES.

An action for damages against a medical practitioner was tried at the recent Croydon Assizes before Mr. Baron Bramwell.

It appeared that Mr. Downes, the defendant in the case, is a medical practitioner residing in Southwark. He has three assistants, two of them being pupil assistants and one senior. On the 5th of June last, the plaintiff, a working woman, called at his shop, and asked one of the junior assistants, as she said, for "Rochelle salts," but, as he said, for "Rochter salts," for which he gave her carbonate of potash or salts of tartar. According to his evidence, he gave her only half an ounce, and there were no questions asked nor directions given as to the mode or quantity in which it should be taken. The woman said that she took a spoonful of it in water, and it caused her violent vomiting and great pain. There was no doubt that it did for the time cause great depression and prostration, but according to the medical evidence, it caused her no serious injury. A day or two after she went to Mr. Downes, the defendant, and declared she had suffered severely, and claimed compensation. Mr. Downes said he could see no symptoms of injury, and that, as she had thrown it off, it could do her no further harm, and that he would give her some medicine to counteract it. Soon afterwards, however, an attorney's clerk, who lodged in her house, came to Mr. Downes to claim compensation. Mr. Downes said, if he found she had sustained any damage, he would compensate her; and subsequently, in order to avoid the vexation of an action, offered to pay as much as £40 or £50, but in vain. A writ was issued and an action brought. It appeared that the attorney's clerk entertained sanguine expectations of the fruits of the action, and even the sum of £200 was mentioned as the probable amount of damages. The woman gave evidence as a witness, and was supported by her daughter. According to her story she had been quite laid up; there were serious symptoms, and even paralysis spoken of as imminent. For the defence medical witnesses who had examined the woman were called, and their evidence showed that there was no real injury.

After a long trial the learned Baron in summing up said, if the assistant had understood the woman as asking for Rochelle salts, and had given her the carbonate of potash for it, or if he had not taken care to ascertain what it was she wanted, the defendant would be liable; but if he gave her what she asked for, then, as she did not ask for directions about its use (though it would have been better to have given them), the defendant was not liable. Even, however, though the jury found for the plaintiff, there would remain the question of damages, as to which the learned judge observed there were many circumstances which required consideration; the case must be looked at as a whole; and there was strong evidence of undoubted witnesses that the woman had sustained no real injury at all. Moreover, there was great reason to suspect that it was the attorney's clerk, rather than the woman, who was interested in the action.

The jury, after a brief consultation, gave a verdict for the plaintiff for one farthing.—*Clerkenwell News.*

Alleged Attempt to Poison by a Lady.

At Brighton, on Friday, August 18, Christiana Edmunds was charged before the magistrates, with attempting to administer poison to Emily Beard, with intent to commit murder.

It was stated that recently parcels containing poisoned cakes had been sent to several private families in the town. In each case the parcel was forwarded anonymously and was prepaid; the contents were generally similar, and the handwriting appeared the same. Among the persons who said that they had received such parcels was the prisoner. A reward was offered for the detection of the offender, and eventually the prisoner was apprehended. The accused is the lady who, at the inquiry into the cause of death of a boy after eating some chocolate creams,* deposed that she had been made ill by eating creams purchased at the same shop, and had consequently had them analysed, when they were found to contain poison.

Mrs. Emily Beard, wife of Dr. Beard, deposed that on Thursday in the previous week she had received a parcel by rail, which upon opening she found to contain some cakes, preserved fruits and gingerbread nuts, and a note saying that the cakes were for the children, but that some packed up separately were flavoured for herself. She believed that one cake was wrapped up in the note itself. On cutting it through, she noticed something white in the middle which looked like unbaked flour. She sent it all away by the servant, and afterwards two of the servants, Emily Haggett and Margaret Knight, were taken ill. She had known the accused five or six years. About a year ago while visiting her, Miss Edmunds had taken some chocolate creams from her pocket, saying she had brought them for the children, and placed one in witness's mouth. It had a very unpleasant, cold, metallic flavour, and witness went out of the room and spat the whole of it out, but notwithstanding saliva continued to run from her mouth the whole of the night, and she was unwell from diarrhœa the next day.

Dr. Beard said that he had received several letters from the prisoner, one of which was afterwards read. It contained several allusions to the analysis she had obtained, and the evidence given by her at the inquest. Dr. Beard said the prisoner had been in the habit of writing to him for about a year. He had told the prisoner that she must not continue to do so. In consequence of the prisoner expressing a wish that the intimacy with his family, which had been broken off after the chocolate affair, should be renewed, he had objected, on the ground that he feared she had attempted to poison his wife. This charge, however, under threat of an action, he had been obliged to withdraw, because he felt he could prove nothing, and he knew his wife would be on her guard.

Isaac Garrett said: I am a chemist carrying on business in the Queen's Road. On the 8th of June a boy brought to me the following note in a sealed envelope:—

"Messrs. Glaisyer and Kemp will be much obliged if Mr. Garrett could supply them with a little strychnia. They are in immediate want of half an ounce, or if not able a smaller quantity will do. Will Mr. Garrett send it in a bottle and sealed up. The bearer can be safely trusted with it.

"Glaisyer and Kemp, 11, 12, North Street."

I questioned the boy, but refused to send the strychnia without an order from the firm. I also told him I could not supply them with the quantity they required, as I only had a drachm. The boy returned within an hour, with the following order sealed up in an envelope, in which 2*s*. 6*d*. was enclosed to pay for the strychnia:—

"Messrs. Glaisyer and Kemp will be quite satisfied with a drachm of strychnia till their own arrives, and thank Mr. Garrett for supplying them. Their signature has always been sufficient before in their business transactions. Should Mr. Garrett feel the least hesitation in supplying them, they must apply elsewhere.

"Glaisyer and Kemp, 11 and 12, North Street."

Accompanying this was the following order:—

"One drachm strychnia, for Glaisyer and Kemp, Chemists, 11 and 12, North Street, June 8th, 71."

I thereupon put the strychnia into a small bottle, sealed the cork down, labelled it "poison," addressed it to Messrs. Glaisyer and Kemp, and gave it to the boy. The 1*s*. 3*d*. change I wrapped up with the bottle.

Two or three days previous to the 19th of July I received the following letter, contained in a sealed envelope. It was not brought by the same boy who came with the note purporting to come from Messrs. Glaisyer and Kemp:—

"*Ship Street, July*, 1871.

"Sir,—I shall be much obliged if you will allow me the loan of the book wherein you register the poisonous drugs you sell. It is merely in furtherance of an inquiry I am making as to the sale of certain poisons, and bears no reference to anything you have sold or any irregularity in the selling, but only to aid me in my investigation. You will tie up your book and send it at once by

---

* See *ante*, p. 17.

the bearer; it shall be returned to you soon, as you may need it. Yours truly, D. Black, Borough Coroner."

I sent the book by the boy, and it was returned within an hour, wrapped up in the same paper. Subsequently Dr. Brown called upon me and desired to see the book. I then discovered that several of the leaves were missing. The missing part did not contain the entry relating to the strychnia had by Messrs. Glaisyer and Kemp; they related to business transactions about six months since. The book was perfect when it was fetched by the boy; it had not been out of my possession before. Two or three days afterwards I received the subjoined note, also contained in a sealed envelope, and brought by another boy. A shilling was enclosed in it:—

"Messrs. Glaisyer and Kemp will be much obliged if Mr. Garrett could supply them with 2 oz. of arsenic, or 3 oz. if he can. So please send back directly. Their signature will be sufficient.

"Glaisyer and Kemp, North Street, July 19th."

I did not supply this article, for my suspicions began to be aroused. I thought it singular that Messrs. Glaisyer and Kemp should send such trifling orders. I wrote a note to that effect and sent it by the boy, but received no answer to it. The next morning I went to Messrs. Glaisyer and Kemp's, and in consequence of what occurred on that occasion, I went to the Town Hall and gave information to the police.

Thomas Glaisyer said: I am a member of the firm of Glaisyer and Kemp, 11 and 12, North Street, Brighton. I have looked at the letters spoken to by Mr. Garrett, purporting to come from my firm, and can affirm that they were not written by any one connected with our establishment. We have not received the strychnia referred to, nor the letter which Mr. Garrett wrote to us.

Nathaniel Paine Blaker, surgeon, said: I was sent for on Saturday evening last, at about half-past seven or eight o'clock, to Dr. Beard's, to attend Margaret Knight. She complained of a pain in her stomach and of vomiting. I was told she had been vomiting almost the whole of the afternoon. From the symptoms which showed themselves, and in consequence of what was told me, and of subsequent observations of her symptoms, I can only account for them as the result of some irritant poison. Some vomit was shown me in two vessels. One contained that which she threw up soon after she was taken ill, and the other that which she brought up when I was called to attend her. These vessels I had placed into a cupboard, together with the other cakes contained in the box, and then sealed up the cupboard. Nothing has been done with the vomit since, to my knowledge. Arsenic might produce such symptoms, but I would not swear to it. The cook was not so ill as Knight. She told me she felt languid, and had a pain in her stomach, but there was nothing much in her appearance to attract attention.

The hearing of the case was adjourned. It has been decided to entrust the analysis to Dr. Letheby. A reward having been offered for each of the three boys who were sent with notes to Mr. Garrett, two of them have been already found.

Poisoning by Laudanum.

At the Clerkenwell Police Court, on Tuesday, Rosina Hamilton, a needlewoman, was charged with attempting to poison her two illegitimate children by administering laudanum.

A policeman stated that on the previous evening the prisoner came into the police station and said she had come to give herself up for poisoning her two children. He fetched a medical man and went to her house, where he found the children in an insensible state, and on the table a small milkjug and spoon, both of which had contained laudanum. The prisoner gave him a bottle which smelt strongly of laudanum, and said, "I gave them two pennyworth of laudanum. I bought one pennyworth in the Caledonian Road, but I do not know where I got the other. I tried to get it at a number of shops, but they refused to serve me."

Medical evidence was given that the children were suffering from opium-poisoning, and that though now likely to recover, they would probably have died had they not received prompt medical treatment.

The prisoner was remanded.

Poisoning by Oil of Vitriol.

On Wednesday evening an inquest was held at Upper Norwood, touching the death of John Burman Messenger, aged eight years. The deceased was the son of a fruiterer residing at 3, Chatham Terrace, Upper Norwood. The father was accustomed to clean the shop scales with vitriol, and on Friday last sent one of his errand boys to purchase a pennyworth. He shortly afterwards left, and on his return found that two pairs of scales had been cleaned. The vitriol was in a ginger-beer bottle. He sold ginger-beer. Witness found deceased suffering acutely, complaining of great pain in his chest. He was taken to Dr. Brockwell, who pronounced it a case of poisoning by sulphuric acid. He was then taken home, and expired the following day. The children were in the habit of helping themselves to the ginger-beer. He had no doubt the bottle containing the poison had by some inadvertence got mixed with the other bottles on the counter, and the deceased had drunk a portion. Verdict—Accidentally poisoned.—*Standard.*

Review.

Commentar zur oesterreichischen Pharmacopoe. By Dr. J. C. Schneider and Dr. A. Vogl.

Second Notice.

The special part of pharmacognosy opens with Class I., remedies which are directly recognized as plants or parts of plants; these are divided into two sections, viz. Thallophytica and Cormophytica, the first comprising three Orders, (1) Fungi, (2) Lichens, (3) Algæ; the last nine Orders, (4) Herbæ, (5) Folia, (6) Gemmæ, (7) Flores, (8) Fructus, (9) Semina, (10) Cortices, Stipites et Ligna, (11) Radices, Rhizomata, Tubera et Bulbi, (12) Gallæ.

The names of the single articles under these Orders are given in Latin, German, French and English, and with very few exceptions, these names are given correctly.

The authors expressly state they have not limited themselves to a description of substances embodied in the Austrian Pharmacopœia, but they have included many antiquated remedies still in request, and also new articles which are likely to become important in pharmacy and medicine. A clear distinction in the type of the headings separates at once the officinal from the non-officinal remedies.

Each of the twelve Orders is prefaced by a description of the general characteristics, botanical, chemical, physical, or microscopical, and we shall take opportunity of reporting on some of these prefaces in due time.

Under *Fungi*, the most important and the first on the list, is—

Fungus secalis. Secale cereale, Linn. *Ergot of Rye.*

It chiefly consists of a dirty-white tissue, enclosed in a thin dark violet skin; it contains 31 per cent. of a colourless fatty oil in small globules, soluble in ether, chloroform and boiling alcohol. Wenzell separated in 1864 two alkaloids from ergot, viz. ecboline and ergotine, combined with ergotic acid. The specific action of ergot appears to be due to ecboline, inasmuch as half a grain was found to be as powerful as 20 grains of ergot; ergotine is less active. Wenzell also proved the presence of phosphate of trimethylamin, which, on addition of potash, gives the peculiar smell of herrings.

A large percentage of ergot in corn flour is highly dangerous, and has often been the cause of epidemics (ignis sacer, pestis ignaria), especially in France, also in Brabant, Germany, Italy and Sweden. The detection of ergot in flour is therefore of the utmost importance. The most delicate test is a mixture of one part of sulphuric acid and ten parts of alcohol, which dissolves the colouring matter, producing a beautiful red colour; the specific smell of trimethylamin, on addition of potash, is also decisive; and lastly, the treatment with bisulphide of carbon, which extracts the fatty oil, of which pure flour contains but traces.

Herbæ.

A useful hint is given how to prepare dried herbs for microscopic investigation, so as to give them the required elasticity, viz. to place them for a couple of hours on moistened sand under a bell jar.

Herba Cannabis indicæ. Cannabis sativa, L. *Indian Hemp.*

The hemp cultivated in Europe, on account of its tough bark-fibre and oil, differs but slightly in botanical characteristics from that grown in Asia and Africa, and the more drastic action of the bark is entirely due to climatic influences. There are two varieties of Indian hemp. Gunjah or Ganja, from the mountains of northern India, is of superior quality, but more scarce than Bang or Guaza. Very little is known of the active principles of Indian hemp, the resin and essential oil obtained from the plants appear to be the joint cause of the narcotic action. The resin, cannabine, or hadshischine, has not yet been analysed; it is extremely bitter, soluble in the usual solvents of resins, but not in alkalies: the essential oil, according to Personne, consists of a liquid, cannabene $C_{36}H_{20}$, and a crystalline substance, cannabene hydride $C_{36}H_{42}$. Liford and Martius found oxygen in the oil.

Herba Maticæ. Artanthe elongata, Miq. *Matico leaves.*

The active principles are a resin, an essential oil and tannin. The essential oil is contained in separate large globular cells with thin walls, which are dispersed in the microphyll, but chiefly under the epidermis of the upper side of the leaf; tannin is found in all microphyll cells, besides chlorophyll; sections of the leaf are coloured blackish-green by solution of iron salts.

Another variety, *Artanthe adunca*, Miq., has been imported more recently from South America; the leaves of the last are not serrated, they are underneath rough, stiff, almost leathery, the tertiary nerves project but little, and connect the secondary nerves without forming meshes. The inhabitants of South and Central America designate as matico several herbs which are known as styptics. It is reported that this specific property was accidentally discovered by a Spanish soldier during the War of Independence from Spanish supremacy, who, in default of other means, bound up his wounds with matico leaves; hence the name *Yerva soldado* or *Palo del soldado.*

Herba Absinthii. Artemisia Absinthium, L. *Wormwood.*

Yields from a half to two per cent. of essential oil, contained in separate round glands in all the herbaceous parts of the plants, chiefly in the leaves. Soil and climate exert the greatest influence upon the quality of wormwood; the plant which grows wild in sunny, stony places is the best, whereas if cultivated in gardens it loses much of its medicinal value.

Herba Spilanthis oleraceæ. Spilanthes oleracea, Jacq. *Paraguay Roux.*

Microscopic examination shows in the texture of the leaves, in the barks of the stalks, besides chlorophyll in most of the parenchyma cells, colourless oil-globules, which turn reddish-brown on addition of solution of iodine. In South America, its native country, Paraguay roux, or para creso, has long been known as an antiscorbutic; the tincture made from fresh leaves is officinal in Germany, and is used for toothache.

Herba Galeopsidis. Galeopsis ochroleuca, Lamarck.

This herb has long been used in Germany and France as a popular specific in diseases of the chest; it gained great popularity in 1811, when it was found to be the principal ingredient of a quack medicine, known as Lieber's herbs for consumption: it was received into most Pharmacopœias, chiefly to counteract the Lieber swindle, and although perhaps harmless and useless, it still enjoys a certain popularity.

Herba Lobeliæ. Lobelia inflata, Linn. *Indian tobacco.*

It tastes disagreeably sharp and irritating, resembling that of tobacco, hence its English name; the fresh plant is replete with a white, very acrid chyle, distributed in netlike vessels through all its parts; this is undoubtedly the agent of the medicinal activity, although it is not yet known. The active principle, according to Calhoun, is a volatile narcotic alkaloid, called lobeline, similar to nicotine, combined with lobelic acid; besides this, there has been found in the herb a resin, a gum and traces of an essential oil, and in the seed 30 per cent. of a rapidly drying fatty oil.

Herba Aconiti. Aconitum Napellus, Linn. *Aconite leaves.*

Most Pharmacopœias demand the wild-growing plant for the extract, the only exception is the British Pharmacopœia, which prescribes the cultivated plant.

Herba Cochleariæ. Cochlearia officinalis, Linn. *Scurvy grass.*

The fresh herb on being rubbed developes a pungent, volatile smell, resembling mustard oil; the dried herb has entirely lost its pungency. The fresh, blooming herb yields not more than from 0·02 to 0·05 per cent. of an essential oil ($C_{12}H_{10}S_2O_3$, Geissler), this is not ready-formed in the plant, but is produced by the action of a substance similar to, perhaps identical with, myrosine of the mustard seed. The activity of this substance is destroyed by drying the plant; dried scurvy-grass treated with myrosine yields the essential oil, but not by itself. This oil forms with ammonia, like mustard oil, a crystalline base. The officinal spiritus cochleariæ sometimes deposits crystalline needles of the composition $C_{12}H_{14}O_4$, often also sulphur crystals. The spirit was first used as an anti-scorbutic by Weir, as far back as 1557.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[276.]—AERATED WATERS.—*W. H.* wishes to have a recipe for making gingerade, lemonade, or soda-water with a machine.

[277.]—GOLDEN HAIR DYE.—"*Crinis*" asks for a receipt for a golden hair dye that will not injure the skin.

[278.]—HOT-AIR BATH.—Perhaps some reader would kindly inform me of the best plan of constructing a hot-air bath for drying large quantities of a certain paste; as it has to be thinly spread, a large surface is required. A uniform low temperature, without constant watching, is also an object?—NUBES.

[279.]—ESSENCE OF BAYONNE.—Can any reader inform me of the nature of a substance called essence of bayonne, and where it is to be procured?—J. J. THOMAS.

[280.]—DISPENSING.—The following prescriptions have been handed to me to prepare; I would like to hear the opinion of some of the readers of the Journal on them:—

℞. Potass. Hydr. ʒiij
Aquæ ℥viij M.
Sig. coch. mag. ter in die.

℞. Beberiæ Sulph. ℈ij
Acid Nit. Dil. ʒij
Aquæ ad ℥ij Solve.
Sig. coch. min. ter in die. —George Harvie.

[281.]—DISPENSING.—Will some of your correspondents inform me of the best way to dispense the following prescription:—

℞ Kreasoti gutt. iij
Zinci Oxydi gr. iij
Mucil. Acaciæ q.s.
ut fiat pilula, ter die post cibos sumenda.
Mitte xxiv
in argento.

It has been dispensed previously, but I have experienced great difficulty in turning out a nice pill.—W. P. Parry.

[282.]—DISPENSING.—I have just dispensed the following prescription, which presented a thick appearance, but no doubt the mixture is intended to be clear.

Can any reader kindly inform me the best mode of manipulation?

℞ Potass. Bromid. ʒiv
Spt. Ammon. Arom. ℥j
Spt. Chloroformi ʒiv
Syr. Aurantii ℥j
M. Inf. Aurantii ℥iiss. —Aquila.

[283.]—BROMIDE OF QUININE, BROMIDE OF STRYCHNINE, AND BROMIDE OF MORPHINE.—"*A Glasgow Chemist*" will feel obliged for some particulars regarding the preparation, strength, dose, etc., of these articles.

[284.]—SYRUP OF CHLORAL HYDRATE.—A few days ago, I had a prescription brought to me, of which the enclosed is a copy.

℞ Syrup. Hydrat. Chloral, ℥ij.
Half to one teaspoonful to be taken at bedtime in half a wineglass of cold water when required to procure sleep. —J. W.

I was told that a child of ten years was going to take it. What strength ought it to have been made? Is there a regular form by which medical men take their standard, the same as they do in B. P. preparations? Had it been for an adult to take, of course the strength would have to have been stronger than for a child. If any reader can enlighten me on this subject, I shall be obliged.—"Exhibeatur."

CARBOLIC ACID FOR SNAKE BITES.—We learn from the *Journal de Méd. de l'Ouest*, and *Bull. Génér. de Thér.* that Dr. Weir Mitchell, from observations on the bite of the rattlesnake, and MM. Gicquain and Viaud Grand-Marais, from observations on that of the viper, have arrived at the conclusion that the application of carbolic acid immediately on the receipt of the injury prevents both local and general poisoning. The pure acid, however, if applied in too great quantity, is liable to produce sloughing, and even dangerous symptoms; hence it is best used in the proportion of two parts of acid and one of alcohol. Given internally, or applied to the wound at a late period, it produces no effect. It is believed to act, not by neutralizing the poi son, but by causing contraction of the small vessels, and thus preventing its absorption.—*Nature*.

The Pharmacy Bill.

Sir,—In the Journal for August 5th you insert two paragraphs from "the Report recently made by the Medical Officer to the Lords of Her Majesty's Privy Council." I regret that you have not published the whole of that Report, as its publication might probably have had the effect of stirring up every member of the trade to keep a very vigilant eye on the doings of that medical officer. However, the two paragraphs you have published contain quite sufficient to make every member of the trade keep a strict guard for the future, to prevent and to defeat any other amended Pharmacy Bill of so objectionable a character as the one which has been defeated in the present session of Parliament.

I do not agree with Mr. Simon in his belief that it was "an accidental oversight in legislation in the Pharmacy Act of 1868, that while all other powers were to be exercised for public purposes by the Council of the Pharmaceutical Society, the first section of that Act vested in the commonalty, and not in the Council, the very important power which that section confers." I feel persuaded that the twelve thousand chemists of this country will never submit, without a much greater struggle than they have now passed through, to permit either the Privy Council with its medical officer, or the Council of the Pharmaceutical Society, to make such rules as they may think proper for the conducting of the business of a chemist and druggist, without first submitting them for the approbation of the members of the Society. His Report is not a correct, but a very unfair, statement as to the selling of poisons, as the Act itself contains the most stringent regulations as to the sale of them. Any member of the Privy Council who is unacquainted with the Pharmacy Acts of 1852 and 1868 would be led to believe there were no rules or regulations in existence as to the sale of poisons.

The first section of the Pharmacy Act of 1868, which vests in the Pharmaceutical Society (with the consent of the Privy Council) to recommend regulations as to the keeping, dispensing and storing of poisons, is one entirely of a permissive character, to be used only if circumstances should arise to require them. I assert that no case has been made out, that the public have never asked for, and that circumstances have not arisen to justify the Government in, such a needless piece of interference with the business of probably twelve thousand chemists and druggists in the kingdom.

In proof of what I say, I point with proud satisfaction to the fact that the deaths from accidental poisoning, from errors in dispensing, do not amount to two per annum on the average of many years. I very much doubt whether any rules or regulations could be framed which would lessen that number; but those who know the business, and are capable of judging, feel that if left to the Privy Council, not one of whom knows anything about the business of a chemist and druggist, they might make such rules and regulations for "the storing of poisons" as would be very likely to largely increase the number of cases of accidental poisoning.

I also assert that the public have never asked for the alteration of the Pharmacy Act of 1868. I have never seen in any newspaper either a letter or a leading article asking the Government to undertake such a needless piece of legislation. The business with which I am connected has been in existence nearly a century, and during that long period, as far as I can ascertain, there has never been a single case of accidental poisoning, or anything approaching a serious mistake.

No penalties which the Government could devise in cases of accidental poisoning could equal that which invariably follows such cases, namely the utter ruin of a man's business. It is to the interest of every member of the trade to make such rules and regulations for the prevention of accidents as the very varying circumstances of a chemist's business require. The regulations which are adapted to a town business are quite unsuitable for a business in an agricultural district.

I hope every town in the kingdom will organize, and be prepared for the assault on the trade which will probably be made next session; and also consider well who are to be returned to the next Council to represent their interests.

If the Government are anxious to make an alteration in the law, the best alteration they could make would be to bring in an Act to separate entirely the practice of pharmacy from the practice of medicine,—that is, that all medicines shall be prepared and dispensed by educated chemists, and that the prescribing of remedies and the art of surgery shall be confined entirely to medical men.

If the Council of the Pharmaceutical Society were to devote more of their time and of their funds to establish provincial schools of pharmacy, to improve the education and status of the country members, their time and their means would be better employed than they hitherto have been. The country members contribute a very large proportion of the income of the Society, and a very small amount has been expended for the benefit of Pharmacy in the provinces. Neither have the country members been indifferent to the claims of the Benevolent Fund, if other towns have contributed in the same proportion as Hull has. I trust the Council, for the future, will endeavour to promote harmony between town and country, and that they will also have the pluck to refuse to be dictated to or led by the nose by any medical man. The education which the present generation of chemists must receive, and the examinations which they must pass, ought to protect them from such interference, and fit them to make suitable rules for the management of their business.

Atkinson Pickering.

Hull, August 14th, 1871.

Sir,—I have but this day returned home, having spent the last fortnight in regions inaccessible even to the Pharmaceutical Journal. I have thus but just seen Mr. Sandford's letter in the impression of the 5th inst., and I have thus also lost the proper moment for replying to an opponent's letter. There are, however, two points in it to which I wish to refer, even though somewhat after date.

Mr. Sandford asks the question, "Does not Mr. Schacht know that even in his own district a score of persons dealing in poisons may be found who take no precaution whatever?" To this I wish to answer that I do *not* know it, and that I should like to be informed if Mr. Sandford knows it, or upon what authority he makes the insinuation.

In another part of his letter Mr. Sandford refers to my charge of "treason" against certain "good men and true," who he hopes "will still command the confidence and goodwill of their fellow-members." To this I wish to say that as regards "goodwill," no one is more sincerely capable of endorsing Mr. Sandford's hopes than myself. My charge is exclusively a political charge. I have no doubt many of those whose conduct in this matter appears to me to be "treasonable" believe themselves to be patriots, and all such men have my personal good-will, now as ever, though, for the time at least, they have utterly lost my political confidence.

Only one word more. I regret this controversy as much as any one, but I refuse to accept the responsibility of the agitation. They are responsible who seek to impose a law upon the trade, five-sixths of which (as Mr. Betty shows) appear to be opposed to it. Under such circumstances agitation must follow, and, as it seems to me, must continue so long as the threat to persevere in the attempt is continued, and so long as it is human nature that five men should decline to lie down and allow one man to walk over their bodies.

G. F. Schacht.

Clifton, August 17th, 1871.

Plans for the Prevention of Accidental Poisoning.

Sir,—Week after week we are continually reading some new suggestion with regard to the above, until at last, from their multiplicity, they are becoming positively sickening; and more than this, they have a bad influence on the "rising generation" of pharmaceutists, because they tend to make us lose confidence in ourselves. What may be the use of the examinations of the Pharmaceutical Society if they are not to get a superior class of men into the trade, men who fully appreciate and feel the responsibility of their situation? and what may be the use of mechanical aid to men of this class? I never see a suggestion for the prevention of accidental poisoning but that I feel thankful that the general public do not get access to our trade journals and see all these "bright ideas" for the prevention of poisoning, for they would most certainly think we were all "losing our heads."

Sometimes I almost fancy that your correspondents must be joking when they propose such things as bells or galvanic apparatus to be attached to the bottles, for they could never have thought on the practicability of the schemes they suggested, if they did I am pretty sure they would never have recommended them.

I don't believe that any mechanical arrangement that may be invented will be any sort of a safeguard after the novelty of the affair has worn away. For instance, supposing something was adopted which was intended to attract your notice by sound? What would be the result? Why, simply the same as taking up your abode near a railway station,—for the first few nights you cannot sleep with the noise, but soon you get used to it, until at length that very noise acts as a sort of lullaby, and you would find it hard to go to sleep without it. And so it would be with anything in the way of sound that could be adopted,—it would in time attract no notice whatever. And the same rule would apply if we trusted to the sense of touch, or any other sense, except the eye and the brain. I am sure it is quite time to say "good-bye" to all these absurd suggestions, or else we shall be running our heads against a post, if we have not done so already. What a true fable is that of the frogs who cried out for a king! Every one knows the result of their pleadings; and if our trade at present does not bear a close resemblance to the frogs, nothing in this changeable world ever did. We cried out for government; we have obtained it in the Pharmaceutical Society. Yet still we are not happy. We are grumbling again, and if we don't mind we shall get fettered by a government of another sort; and who knows what the result would then be? We have narrowly escaped this latter predicament, and, unless some agreement is made between ourselves before next session commences, why then look out for storms, for we shall then surely find ourselves "out of the frying-pan into the fire."

C. B. A.

Penzance, August 22nd, 1871.

Poison Bottles.

Sir,—Your correspondent "Scotus," in my opinion, just adds another difficulty in place of removing one, in regard to the keeping of poison bottles. The expense necessary to purchase several dozens of bayonet-catch stoppered bottles would prove an insuperable objection to many hundreds in the trade.

In regard to the india-rubber capsules he is mistaken as to the necessity to use both hands. Although I deprecate the haste he alludes to in dispensing prescriptions, and would always prefer the dispensers in my pharmacy placing bottles containing dangerous drugs fairly on the counter before them; yet if it is imperative to dispense against time, let the rubber cap be fixed to the stopper, by wrapping a bit of coarse adhesive rubber tape round the stopper, and allow the lower edge or ring of the cap to rest on the rim of the bottle, in place of over it, when the stopper can be as easily removed and replaced with one hand as any stopper not so protected.

M. P. S.

X. Y. Z. is recommended to communicate with the Registrar.

"*Theta*" writes to us, urging the Council to permit "Modified men," on passing the local Preliminary examination, the same privilege of presenting themselves for the Major examination as though they had passed the Minor. He had better make that application to the Council; we cannot see that we should aid his views by publishing his letter.

Communications, Letters, etc., have been received from Mr. P. Miller, Mr. F. Pattison, Mr. R. Carter Moffat, Mr. S. H. D. Sheppard, Mr. Crafton, Mr. Bingley, Mr. J. Parrott, W. D. S., C. B. A., A. A., "Sulphur," "Aquila."

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page 142.*)

Part III. European and African Mylabridæ.

Having already enumerated the Asiatic species, more or less economized as vesicants, it remains to give some account of the European and African species. Of the 275 species already known, at least 160 are African, so that Africa may be regarded as the head-quarters of the genus, but we are very deficient of information as to the extent to which any of them are employed as vesicants. Only three species have been recorded in the New World, one of these is certainly a *Lytta*, and both the others are very doubtful. It is probable that no true *Mylabris* is found in America.

Floral Mylabris, *Mylabris floralis*, Pall.; hairy, black; elytra blue-black, with two yellow bands, and two spots, of which one is at the base, the other at the apex.—Pall. Icon. t. H. f. e. 8; Schæff. Icon. t. 151. f. 3. *Mylabris Füsselini*, Biz. Fn. G. xxx. 18; Bellb. Mon. t. ii. f. 12, 13. *M. variabilis*, Tausch. Mem. Mosc. iii. t. 10. f. 5. *M. fasciatus*, Füssel. Verz. p. 20. 398. t. i. f. 1 *c*.

Head hairy, black, punctate. Thorax scarcely longer than broad, black with black hairs, punctate. Scutellum black, hairy, punctate. Elytra three times as long as broad, rugoso-punctate, bands and spots evidently punctate, with scarcely the rudiments of elevated longitudinal lines, subvillous, hairs at the base longer and blue-black; a solitary spot by the scutellum, two dentate, wavy bands, one above, the other below the middle, and one spot at the apex; all the bands and spots yellow. Wings hyaline, tawny. Breast and abdomen rugoso-punctate, black, rather shining, hairy. Feet black, hairy.

Native of Germany, Switzerland and other parts of Europe.

It is stated in Christison's 'Dispensatory,' and some other works, that this is employed as a vesicant in some parts of Europe, under the name of *Mylabris Füsselini*.

Twelve-spot Mylabris, *Mylabris duodecimpunctata*, Oliv.; hairy, black; elytra brick-red, with six black points in pairs.—Tausch. Mem. Mosc. iii. t. 10. f. 10; Oliv. Ency. Meth. *Mylabris crocata*, Oliv. Ent. iii. t. 2. f 23; Billb. Mon. t. 7. f. 8. *M. cyanescens*, Illig. *Meloe crocata*, Pall. Icon. p. 87. t. E. *Lytta lutea*, Pall. Iter. p. 222.

Head hairy, black, punctate. Thorax a little longer than broad, hairy, black, punctate. Scutellum black. Elytra three times as long as broad, rugose, marginate, with scarce the rudiments of elevated lines, yellowish, with six black points in pairs, of which two are before the middle, two about the middle, the fifth behind the middle, at the suture, and the sixth near the apex. Breast and abdomen black, hairy, punctate. Feet black, hairy.

Native of Hungary, Russia, France, etc.

This species is misquoted by Moquin-Tandon (Med. Zool. p. 135) as *M. cyanescens*, where it is stated to have been recommended by M. Farines, a pharmaceutist of Perpignan. In Gemminger and Herold's Catalogue, doubtless on the authority of Marseul, the *M. cyanescens* of Illiger is quoted as synonymous with the *M. crocata* and the *M. duodecimpunctata* of Olivier.

Variable Mylabris, *Mylabris variabilis*, Pall.; villous; black; elytra shining black, with three ochraceous bands, the first interrupted, and the upper margin coloured.—Pall. Ic. p. 81. t. E. f. 7; Oliv. iii. p. 10. t. 2. f. 14 *b*; Billb. Mon. t. 3. f. 3. *Meloe fasciatus*, Füssel. Verz. p. 20. T. f. 1 *c*.

Head black, hairy, punctate. Thorax scarcely longer than broad, black. Scutellum black, hairy. Elytra three times as long as broad, shining black, somewhat hairy, hairs very short and black, with three ochraceous bands, the first at the shoulder interrupted, the second and third waved, the black apex also broad with the margin yellowish or ochraceous, roughly punctate, with four elevated longitudinal lines. Wings hyaline, tawny at the apex. Breast and abdomen black, punctate, hairy. Feet black, hairy.

Native of Russia, Germany, and Switzerland. Included by Moquin-Tandon with vesicants on the authority of Dr. Bretonneau (Annales des Sc. Nat. xiii. 1828. p. 78).

Spotted Mylabris, *Mylabris maculata*, Oliv.; black; elytra rufous, with two black spots at the base, and posteriorly two broad, black, somewhat interrupted bands.—Oliv. Ent. iii. 47. t. i. f. 9; Billb. Mon. t. 6. f. 10–14; Tausch. Mem. Mosc. t. x. f. 7. *M. bimaculata*, Oliv. Ency. Meth. viii. p. 93; Jacq. Duv. Gen. Col. iii. t. 93. f. 463.

Smaller than *M. pustulata*. The body is generally black, the elytra are rufous, marked towards the base with two black spots, at the middle with a broad band, nearly interrupted at the suture and narrowed towards the margin; near the apex another band, equally black, slightly dentate.

Native of Russia, Egypt and the East.

This species is stated by Gervais and Van Beneden (Med. Zool.) to be employed in Greece.

Olive-tree Mylabris, *Mylabris Oleæ*, Cast.; black; elytra brick-red; apex and two bands black, the foremost abbreviated laterally, the second entire, the margin not sinuated.—Cast. Hist. Nat. ii. 1840, p. 269; Erichs. Wagn. Reis. iii. 1841. p. 185. t. 8; Lucas, Exp. Alg. p. 387.

Antennæ black. Body black, rather shining. Head as broad as the thorax, closely punctate. Thorax laterally slightly rounded, punctate, subrugulose. Elytra smooth, densely and finely punctate, brick-red, with three black bands, the first scarcely touching the margin, the second in the middle of the elytra, the third apical, all with their margins nearly entire, the space before and behind the middle band nearly equal, the basal not more than half as broad. Length 10–12 lines.

This species is a native of Algeria, Tangiers and Morocco. M. Guérin-Méneville has named it as a vesicating insect, on whose authority it is cited by Moquin-Tandon (Med. Zool. p. 135). It is a large species, being equal to the majority of specimens of *M. phalerata*.

In Mozambique, Peters. (Reise, 1862) enumerates and describes eleven species, of which it is hinted that some are employed as vescants. Those named are *M. catenata*, *M. dicincta*, *M. pruinosa*, *M. ruficrus*, *M. serricornis*, *M. tettensis*, *M. tricolor*, *M. trifurca*, *M. tripartita*, *M. tristigma*, *M. lanuginosa*, and the *M. Burmeisteri* of Bertolini.

NOTE ON TINCTURE OF KINO.

BY A. F. HASELDEN, F.L.S.

The observations of Mr. J. W. Wood in the Pharmaceutical Journal, 19th August, 1871, upon the tincture of kino, U. S. Pharmacopœia, are worthy of recognition and consideration. The inconveniences arising from the gelatinizing tendency of the tincture are equally applicable to the form of the P.B. As a rule, tincture of kino is not in constant demand, but it is frequently ordered in combination with other remedies during a prevalence of diarrhœa, more especially at this season of the year, and many practitioners prefer it to catechu. Tincture of kino is also used as an adjunct to mouth-washes, and any method of making or keeping it so that it shall remain unaltered will be a desirable acquisition.

For some years past I have preserved tincture of kino from gelatinizing by keeping it in bottles holding two ounces only. Once commenced, this quantity is soon consumed, and there is no fear of a change taking place before so small a bottle is emptied. A few days ago I used the last of some prepared in 1869 stored in this manner. Four ounces also in a bottle kept filled did not gelatinize during the same period of time; but I doubt if this would be constant, as I have never succeeded in keeping a larger quantity, especially when the bottle was only partly filled. The addition of glycerine, as suggested by Mr. J. W. Wood, cannot, I think, be objectionable, and for other than the Pharmacopœia tincture I shall be tempted to try it, and hope to obtain an equally desirable result.

LÜNEBURGITE.

BY C. NÖLLNER.

Lüneburg, in Hanover, has for centuries been known for its manufacture of salt by evaporation. Dr. Volger has lately sunk a shaft to reach the deposits of rock-salt and possibly of potash-salts, and as Mr. Nöllner has analysed the minerals brought to light, he gives his opinion on the formation of saline deposits in general. He takes it for granted that the deposits at Stassfurt and other places, have been formed by the evaporation of sea-water. In this process chloride of sodium and gypsum separated first, after that the sulphates, then the chlorides of the alkalies, and, lastly, the deliquescent compounds of chloride of calcium and magnesium. Together with the last layer of chlorides other compounds separated, which were formed by decomposition in such manner that the deliquescent chlorides could give rise to but little soluble salts. Foremost among this class stand the boracites, which always contain chlorides, because every crystal includes some of the surrounding mother-lye.

Again, the lower strata of rock-salt contain gypsum with an equivalent of water, but the upper deliquescent chlorides contain anhydride, because the *concentrated* solutions of $CaCl + MgCl$ required all the water. In like manner artificial boracite, soluble to the extent of only 3 per cent., separates from the last mother-lyes in saltpetre refining; whereas, if it had been ready found from the beginning, it would have separated long before the potash saltpetre. For the same reason such saltpetre, containing borate of magnesia, with often 18 per cent. of chlorine, becomes richer in chlorine the oftener it is washed. Not only boracic acid, but also phosphoric acid, is found in these salts separated from sea-water, especially in Stassfurtite and in the boracites just mentioned, but most of all in the mineral which has been discovered at Lüneburg, and which, therefore, has been named Lüneburgite. Now, if the products of sea-water, formed by evaporation, contain phosphoric acid, boracic acid and fluorine, it stands to reason that these substances must originally have been in the sea-water; this had never yet been ascertained, but these substances are necessary for the formation of fish-bones, which can only be produced from the sea-water, as fish and their food live in the water.

Mr. Nöllner then dwells on the question of the evaporation of sea-water, but this is only of local interest.

The mineral was found to have the composition, $2MgO.HOPO_5 + MgO.BO_3 + 7HO$,

being MgO . . .	25·10	per cent.
PO_5 . . .	29·83	"
BO_3 . . .	14·82	"
HO	30·25	"
	100·00	

—*Buchner's Repert. für Pharm.* viii. p. 484.

HISTORICAL OUTLINES OF PHARMACY IN SPAIN.

BY DR. T. B. ULLERSPERGER, OF MUNICH.

In tracing back the history of Spanish pharmacy to its earliest infancy we must go to the general history of the profession, which records the gradual rise and development of the craft. The knowledge and experience of the ancient Greeks were personified by them; they identified the traditions of former times with a Melampus, a Chiron, or Æsculapius; philosophers and healers at that time, the true and only inquirers of nature, were the representatives of pharmacy; Hippocrates, Aristotle and the Esculapians were, to a certain degree, pharmacognosts. Pedanius Dioscorides appeared as a pharmaceutical writer; his works, to which at a later time the 'Alexipharmaca' was added, were made widely known by Mathioli. Nero's physician, Andromachus, was the first to take the title of archiates, or chief physician, and he gave his name to a nostrum, which even at the present day is largely sold in Venice and Madrid, viz. the theriaca Andromacha. Galen concentrated into practical application all the experience hitherto gained. The alchemy of the ancient Arabs, with all its transmissions from the magicians, had already participated in medicine, and the introduction of remedies from the mineral, animal and vegetable kingdoms became more sharply organized. But much superstition was mixed up with the use of plants, and the disgusting administration of excrements was pushed forward, and the prescription of precious stones was carried out to a ridiculous extent. This stage in our history is generally known under the name of the Galeno-Arabic period; the African Arabs of the Alexandrian school, trained in the remnants of Ptolemaic doctrines, in conjunction with Jewish healers and learned rabbis, carried much relating to remedies and their preparation from one shore of the Mediterranean to the other.

And here commences the true special history of Spanish pharmacy, still intimately united to the art of healing. We now meet with a very peculiar position of affairs. The Arabs had conquered part of Spain; Hispania had become a Roman province; Arabs and Romans predominated alternately; Arabs and Spaniards united to Mozarabs. The remnants of mysticism, transferred from the Greeks to the Romans, superstition, the self-illusion and deception of the magicians and Arabic alchemists, had to be destroyed; the best medical schools were filled by Arabs, following the Arabo-Greek system; Hippocrates' system, modified by a little Galeno-Arabism, prevailed in medicine. From the ninth to the eleventh century the Arabian schools flourished, the Arabian physicians considerably increased the number of remedies, and excelled in most complicated prescriptions. Galen's theory of putrefaction, originally Aristotle's idea, necessarily domineered over the whole of medicine. But with the expulsion of the Moors from Spain, under Ferdinand the Catholic and his queen Isabella, the influence of the Arabs and the Spanish Moors gradually died away, although it can be traced to the sixteenth century, when the celebrated physician of Philip II., Franz Valles of Covarubias, formerly professor at the University of Alcala de Henares, became one of its most strenuous supporters. At the time of the Saracens pharmacy became separated from the study of medicine in the renowned school of Alexandria. The Valentians and Catalans were amongst the first European people who fostered pharmacy. The enlargement of the materia medica,—beginning from the time of Alphonse the Wise, 1252, and to which the Crusades assisted,—furnished many subjects for investigation; chemistry gained more positive ground, it became incorporated into pharmacy, and the union between the latter and the healing art became more and more intimate.

This historical state of things no doubt had its origin in the circumstance that the most celebrated magicians and alchemists were of Arabian origin, while the most renowned physicians were either Jews or Arabs or Moorish Spaniards. The great acquisitions reserved for future centuries were the gradual amalgamation of a certain knowledge of remedies with technical pharmacy and the enrichment of the materia medica by chemical and pharmaceutical preparations. In this respect the time of the Abasides of the Orient stands out most praiseworthy. Curt Sprengel's 'Arabum Res Herbaria' is our great authority of the Arabic influence; also the works of Monte Cassino, who had lived for forty years among the Arabs, and who in his book 'De Gradibus,' 1536, recorded all Arabian remedies. The importation of many new drugs from recently discovered parts of the globe, and the foundation of botanical gardens, are proofs of special advancement. Among the most important discoveries of new drugs that of the cinchona bark in 1638 stands foremost, and it is well known that the Spaniards were the first to import it into Europe.

The first botanical garden was founded under Philip II. J. Pedro Esteve investigated the plants of the kingdom of Valencia; and Don Juan Fragoso, of Toledo, chirurgeon to the same king, travelled for the same purpose with Don Francisco Hermandez through the province of Seville. The Spaniards claim the discovery of making sea water palatable by distillation in the sixteenth century. Dr. Andrés Laguna wrote in 1566:—"Hacese el agua marina dulce ò a lo menos salobre y potable colandola por arena, destilandola en alambiques," etc. Towards the end of the fifteenth century the Spaniards, who figure prominently in the history of syphilis, assisted in the introduction of mercury and of the various ligna.

The bath forms a peculiar speciality in Spain. The Romans had popularized the use of baths in this province of theirs; they erected solid and spacious buildings for the purpose, the remains of which still exist. The Arabs adopted the custom; but the mischief created by the meeting of the two sexes induced Alonso VI. to prohibit the use of public baths and to destroy the buildings. Until the eighteenth century baths and mineral springs have been much neglected, which is the more surprising as the peninsula is peculiarly rich in medicinal springs. More recently this great mistake has been somewhat rectified, but analyses of many important springs are still wanting. Many foreign and native mineral waters are sold by pharmacists in Madrid and other towns.

(*To be continued.*)

THE HONEY TRADE.

BY P. L. SIMMONDS.

(*Continued from page* 168.)

Considerable quantities of honey are produced by the wild bees in the woods of North America. Bee-hunting is a most fascinating pursuit in the backwoods; the returning bee laden with sweets is watched to its home, and 150 lb. of honey are sometimes found in a single tree. The bee is a more adventurous colonist than man, and is always the precursor of cultivation in the Transatlantic forests. The keeping of bees is an object of domestic attention also in Canada, where some 10,000 or 15,000 hives indicate the produce of honey and wax. In Australia the natives are also very skilful in bee-hunting, and they adopt the following ingenious plan to discover their hives. A party of ten or twelve of them having caught an Australian bee, an insect not much larger than our common fly, attach to its body, with a gum that exudes from the mimosa, a little light white down, taken from the eagle or ibis. This is done as much for the purpose of causing the bee to fly slowly as to make the object as large and white as possible; they then, with a simultaneous shout, start off, running to and fro, following the movements of the bee for more than a mile, until the insect lights on its hive in the hollow branch of a gum-tree. In this manner the blacks collect abundance of honey, and the Australian honey greatly excels our finest heath honey.

The climate of Tasmania is most favourable for bees. The flowers of the eucalypti and mimosa furnish food for them, and the honey sent to the different European Exhibitions was much admired. In some parts of the colony, as at Perth, Bothwell, Ross, etc., old tea-chests and boxes are used for beehives and honey is procured by the ton. It is sold in the interior from 4*d*. to 6*d*. a pound, and is used by the settlers either in comb, or as mead or in the manufacture of beer. Swarms of bees which have escaped take possession of hollow trees; occasionally more than 100 lb. of honey are taken from a hole in a gum-tree.

The Arabs collect the bees in the bark of the cork-tree, formed into a cylinder, which they smear with honey to entice the bees to enter; they then close up the extremities, leaving only a small opening as a passage for the swarm; these tubes are extended lengthways on the ground and surrounded with thick bushes. It is almost incredible how much honey and wax they procure from them; the first serves them for food, and the latter is an article of commerce.

The *Apis fasciata* of Latreille appears to have been domesticated in Egypt ages before the hive bee of Europe was known. Niebuhr informs us it is extensively cultivated there at present, and that he met on the Nile, below Mansura, a convoy of 4000 hives, which were being transported from a region where the flowers had passed to one where the spring was later. The domesticated bee of Egypt affords of honey no very limited supply, but it is rather to the wild species of the same continent, inhabiting the endless forests, that the greater proportion of honey is derived, the quantity in some regions being remarkably abundant; so much so that various tribes pay their yearly tribute with it. Sir J. E. Alexander, in his expedition of discovery into the interior of Africa, informs us that beeswax on the Orange river could be procured in very great abundance. A Namaqua, who had a waggon, assured him (and he had no reason to doubt his word) that on a honey hunt he had filled his waggon with skin-sacks of honey alone, and the side planks in two or three days. It is to be regretted that the name of the bee is not noticed. In 1830 no less than 242 tons of beeswax, worth £100 per ton, was exported from the Gambia, and it appears that in the Mandingo country honey is retailed at 2*s*. 6*d*. per gallon. A considerable quantity of wax is also imported from the Gold Coast. The wax is sometimes attacked by the larvæ of a species of tinea, and the weight consequently greatly diminished: this robbery might, no doubt, easily be prevented.

Mr. W. Tegetmeier, at his apiary, Muswell Hill, has introduced the *Apis ligustica*, or Ligurian bee, an abundant honey collector, which has also been introduced successfully into Germany. The principal species of bees kept for domestic purposes are the following:—*Apis mellifica*, Linn., or the common hive bee of Europe, and which has also been introduced into the United States of America and New Zealand; *A. ligustica*, Spinola, kept in some parts of Italy; *A. fasciata*, Latr. in Egypt, and in some parts of Asia Minor; *A. unicolor*, Fab. in Madagascar; *A. indica*, Linn. at Bengal; *A. Adansonii*, Latr., at Senegal.

The production of honey and wax in Austria, according to the imperial statistical bureau, was in 1854, 547,700 cwt. of honey, and 54,770 cwt. of wax, of the value of about £1,000,000, but as this includes only the produce which enters into commerce, and four out of every five bee-keepers consume their own production, Austria may fairly be said to realize annually £3,000,000 from bee-culture. In the ten years ending with 1859, the imports of honey and honey-water into Austria have ranged from 3000 to 25,000 cwt. per annum, of which about 2000 cwt. were re-exported. Of wax, in the same period, the imports averaged about 5000 or 6000 cwt., of which about 2000 cwt. were re-exported. The total number of bee-hives in Austria in 1854 was returned at 2,733,000, giving an average of 270 to the square mile, and producing for the same average area 58 cwt. of honey, and 6 of wax, worth 945 florins. The rearing of bees is carried on most extensively in the Vayvode, and the Temesia, the Banat, Croatia, Slavonia and Transylvania, on the frontier of Galicia, in Styria, Carinthia and Carniola. In the other provinces this trade is of little consequence or extent.

In the States of the Zollverein, about 7000 or 8000 cwt. of wax are imported annually, of which about 2000 cwt. are re-exported. The import of honey is not specifically mentioned in the tariff; but considering the area, population and industry, the value of the honey and wax produced in the States may be estimated in round numbers at £2,000,000 in value, and with that imported at about £2,500,000. In the Grand Duchy of Baden, there were returned 49,146 hives in 1855, and 75,111 in 1861. In Würtemberg there are about 100,000 hives; but this number might be doubled, if care were taken to provide at hand those plants from which the bees derive their honey, and which abound in the forests, the meadows and the fields of colza, etc. These different plants form a rich spoil, from which this comparatively new industry might derive great advantage. Nature and art mutually combine to produce the different kinds of honey and wax, which afford a large profit to the country. The rearing of bees is extensively carried on in the several parts of European Russia, particularly in the central and southern governments, as well as in the Polish, and in Transcaucasian provinces. This insect acclimatizes up to a very high latitude, even in Siberia. It was long thought that the climate of the latter country was utterly unsuitable for the rearing of bees; but experiments made at the commencement of the present century in the governments of Tomsk, Omsk, and Jenisseisk, have proved the contrary. It has greatly suffered, however, in some provinces, from the destruction of the forests; for the bee prefers well-wooded districts, where it is protected from the wind. The honey procured from the linden-tree (*Tilia europæa*) is only obtained at the little town of Kowna, on the river Niemen, in Lithuania, which is surrounded by an extensive forest of these trees, and where the rearing occupies the principal attention of the inhabitants. The Jews of Poland furnish a close imitation of this honey, by bleaching the common kinds in the open air during frosty weather.

(*To be continued.*)

ACTION OF HEAT ON PROTOPLASMIC LIFE.

BY F. CRACE-CALVERT, F.R.S.

Those investigators of germ-life who favour the theory of spontaneous generation have assumed that a temperature of 212° Fahr., or the boiling-point of the fluid which they experimented upon, was sufficient to destroy all protoplasmic life, and that the life they subsequently observed in these fluids was developed from non-living matter.

I therefore made several series of experiments, in the hope that they might throw some light on the subject.

The first series was made with a sugar solution, the second with an infusion of hay, the third with solution of gelatine, and the fourth with water that had been in contact with putrid meat. The hay and putrid-meat solutions were taken because they had often been used by other investigators; sugar was employed, being a well-defined organic compound free from nitrogen, which can easily be obtained in a state of purity; and gelatine was used as a nitrogenized body which can be obtained pure and is not coagulated by heat.

To carry out the experiments I prepared a series of small tubes made of very thick and well-annealed glass, each tube about four centimetres in length, and having a bore of five millimetres. The fluid to be operated upon was introduced into them, and left exposed to the atmosphere for sufficient length of time for germ-life to be largely developed. Each tube was then hermetically sealed and wrapped in wire gauze, to prevent any accident to the operator in case of the bursting of any of the tubes. They were then placed in an oil-bath, and gradually heated to the required temperature, at which they were maintained for half an hour.

Sugar Solution.—A solution of sugar was prepared by dissolving 1 part of sugar in 10 part of water. This solution was made with common water, and exposed all night to the atmosphere, so that life might inpregnate it. The fluid was prepared on the 1st of November, 1870, introduced into tubes on the 2nd, and allowed to remain five days. On the 7th of November twelve tubes were kept without being heated, twelve were heated to 200° F., twelve to 300° F., and twelve to 400° F.

The contents of the tubes were microscopically examined on the 1st of December, twenty-four days after heating.

Sugar Solution not heated.—There were about 30 animalcules under each field of the microscope, principally *small black vibrios*, 2 or 3 microzymes swimming slowly about, 3 or 4 *ordinary swimming vibrios*, and a few bacteria.

Heated for half an hour at 212° *F.*—A great portion of the life had disappeared, no animalcules were swimming; still this temperature had not completely destroyed life. 4 or 5 *small black vibrios* were observed moving energetically to and fro; 2 or 3 *ordinary vibrios* were also observed moving energetically in the same position of the field, that is, without swimming about.

Heated for half an hour at 300° *F.*—The sugar was slightly charred, but the life was not entirely destroyed, as 1 or 2 *ordinary vibrios* and 1 or 2 *small black vibrios* were observed in motion under the field of the microscope.

Heated for half an hour at 400° *F.*—The sugar was almost entirely decomposed; no trace of life was observed.

Heated for half an hour at 500° *F.*—No life observed.

Remarks.—The black vibrios here referred to are far more opaque than the other varieties of vibrios, and are the most important of all, as I have found them to resist not only very high temperatures, but all chemical solutions. I shall, in my paper on putrefaction and the action of antiseptics, describe the various vibrios and give drawings of them.

Hay Infusion.—An infusion of hay was made by macerating it in common water for one hour, then filtering the liquor, and leaving it exposed to the atmosphere all night, when it was sealed in the small tubes, twelve of which were used for each experiment. The infusion was made on the 4th of November, sealed in tubes on the 5th, and heated on the 7th.

The results were examined on the 1st of December, 1870, twenty-four days after being heated.

Hay infusion not heated.—Fungus matter was observed growing on the surface of the fluids in two of the tubes. On subjecting the contents of some of the tubes to examination, from 20 to 25 animalcules were observed under each field of the microscope. This kind of life resembled small dots moving energetically to and fro; 1 or 2 ordinary vibrios were also present.

Heated for half an hour at 212° *F.*—No fungus matter was noticed on the surface in any of the tubes. A few small black vibrios present in the original solution were also present in this.

Heated for half an hour at 300° *F.*—No fungus matter present, but some of the small black vibrios were still present, although in less numbers.

Heated for half an hour at 400° *F.*—No fungus matter observed. The fluid was filled with irregular masses of coagulated matter, and life had disappeared.

Heated for half an hour at 500° *F.*—No life present.

Gelatine Solution.—A solution of gelatine, prepared of such strength that it remained liquid on cooling, was exposed for twenty-four hours to the atmosphere. It was then introduced into the small tubes, and the tubes sealed. The solution was made on the 4th of November, the tubes sealed on the 5th, and subjected to the different temperatures on the 7th.

The fluids were examined on the 1st of December, 1870, twenty-four days after being heated.

Gelatine Solution not Heated.—There were seven or eight animalcules under each field, five or six of which were quite different to anything observed in the other fluids. They had long thin bodies, swimming with a peristaltic motion. One or two ordinary swimming vibrios were also present; but the small black vibrios were absent.

Gelatine Solution Heated for half an hour at 100° *F.*—Life seemed to have only slightly decreased, and none of the animalcules were swimming. The peculiar animalcule mentioned in the previous paragraph appeared to retain still its peristaltic motion, but not sufficient power to move across the field; a few ordinary vibrios being also observed moving to and fro.

Heated for half an hour at 212° *F.*—A very decided diminution in the quantity of life present was noticeable.

Heated for half an hour at 300° *F.*—No life present.

Heated for half an hour at 400° *F.*—No life present.

Putrid Meat Fluid.—Water was placed in an open vessel, and a piece of meat suspended in it until it became putrid and contaminated with myriads of animalcules. This fluid was placed in the usual tubes, which were sealed on the 7th of November, and heated on the same day.

The contents of the tubes were subjected to examination on the 1st of December, or twenty-four days after having been heated.

Not Heated.—A large quantity of life was present, namely, microzyma and several distinct species of vibrios, among which were a number of the small black ones frequently mentioned.

Heated for half an hour at 100° *F.*—This temperature had but slightly affected the life present, the animalcules being as numerous as in the liquid not heated, and moving as usual. However, one species of very long vibrios appeared to be considerably affected, as they were much more languid in their movements.

Heated for half an hour at 212° *F.*—This liquor differed from all the others in being turbid and coagulated. Life was still present; and although heat had deprived the animalcules of the power of locomotion, still they retained a sufficient amount of vital force to place it beyond a doubt that life was not destroyed.

Heated for half an hour at 300° *F.*—The liquid was quite clear, the albumen (which is coagulated at 200°) appearing to be redissolved. A large quantity of the life in the fluid was destroyed, but some vibrios still remained, the small black ones being the most numerous.

Heated for half an hour at 400° *F.*—All life had disappeared.

Heated for half an hour at 500° *F.*—All life had disappeared.

The results recorded above show that protoplasmic life is but slightly affected by a temperature of 212° F., and that, even at a temperature of 300° F., it is not entirely destroyed, excepting in the case of gelatine. In all the other fluids a temperature of 400° F. is necessary to completely destroy the life. These experiments, therefore, clearly show that the life found by previous experimenters in fluids which have been submitted to heat was not due to heterogenesis, but to life which had remained in the fluids, as I have seen no experiment reported where the temperature to which the fluids were exposed exceeded 300° F.*

I am the more justified in making this statement, as I have repeatedly examined the contents of tubes which had been submitted to a temperature of 400° F., both immediately after cooling and at all periods up to thirty days, and was unable in any instance to detect the slightest trace of life.

This important result corroborates those recorded in my previous paper, and proves that the spontaneous-generation theory is not yet by any means established.

It occurred to me that it might be interesting to examine the influence on pure albumen of the putrid-meat fluids that had been heated, and note whether they still possessed the property of propagating life. A solution was prepared by mixing the albumen of a new-laid egg with pure distilled water free from life (prepared as described in another paper). Equal volumes of this solution were placed in six small test-tubes, which had

* It is with pleasure that I find these experiments to confirm the suggestion of Dr. Beale, in his work entitled 'Disease-Germs, their supposed Origin,' p. 50 (which I read a few weeks ago), that "living forms might live though exposed, under certain conditions, to a temperature of 350° F."

been cleaned with hot vitriol and well washed with pure water. To one tube two drops were added of the putrid meat solution that had been heated to 100° F., to a second two drops of that heated to 212° F., to a third two drops of that heated to 300° F., to a fourth an equal bulk of fluid heated to 400° F., and to a fifth the same quantity heated at 500° F. In the sixth the albuminous solution, without anything added, was kept for comparison.

The tubes were sealed and kept from the 1st of February to the 9th.

RESULTS OF EXAMINATION.

Albumen Solution.—In each drop two or three small black vibrios, moving to and fro.

Albumen Solution, with Putrid Meat Liquor, heated to 100° F.—Abundance of life.

Albumen Solution, with Putrid Meat Liquor, heated to 212° F.—Abundance of life.

Albumen Solution, with Putrid Meat Liquor, heated to 300° F.—Much less life than in the two fluids previously examined.

Albumen Solution, with Putrid Meat Liquor, heated to 400° F.—In each drop two or three small black vibrios, moving to and fro.

Albumen Solution, with Putrid Meat Liquor, heated to 500° F.—In each drop two or three small black vibrios, moving to and fro.

These results clearly show that, at the temperatures of 100°, 212°, and 300° F., life and its germs had not been destroyed, whilst at 400° F. they had; for the results of the examination were in this case exactly identical with those of the albumen solution itself; and the life found was doubtless introduced in the preparation of the solution, and was not due to any life having remained in the fluids that had been heated.

Although perfectly aware of the interesting researches of Professor Melsens, proving that the most intense cold does not destroy the active power of vaccine lymph, still I thought it desirable to ascertain the effect of a temperature of 15° F. on well-developed germ-life, similar to that which had been subjected to the action of heat.

Some putrid meat liquor, therefore, containing a large quantity of microzyma and vibrios, was subjected for twenty hours to the influence of a temperature ranging between the freezing-point of water and 17° below that point, when the ice was melted and the liquor examined. The animalcules retained their vitality, but appeared very languid, and their power of locomotion was greatly decreased.

Two hours after melting the ice, the liquor was again examined, when the animalcules appeared to be as energetic as before.

AMBER.

A very large proportion of the amber appearing in the various markets of the world is supplied by the province of Prussia, including the neighbouring district of Memel. The amber trade in this district is entirely in the hands of one firm, and as their transactions are kept very secret, it is difficult to ascertain its exact extent. The following particulars, which are gleaned from a report by Mr. Ward, her Majesty's Vice-Consul at Memel, are not without interest:—

In the western portion of the province of Prussia, amber is found not only on the seashore, but also in the mountainous ranges of the interior; excepting, however, in rare cases of its appearance in so-called "nests" amber is only to be met with in isolated pieces in the latter localities, so that the profit arising from the amber diggings amongst the hills is but a very moderate one, and may be estimated at about double the amount paid by the proprietors for the wages of the diggers. In East Prussia, however, and especially in that part called the Samland, amber is more abundant, and during the prevalence of certain winds, is frequently thrown upon the shore by the sea in large quantities; it is collected there, as well as fished for in the surf; it is also dug out of the sand-hillocks running along the seacoast. In these sand-hillocks regular beds of amber are found enclosed in a soil of blue clay, which is to be met with at an average depth of about a hundred feet, in a thickness of twenty-five to thirty feet. It is stated that out of some diggings established in those parts, 4,500 lb. of amber were raised in the course of four months of the year 1869. Diggings of this kind exist at present in various spots of the Samland, more especially at Wangen, Sassan, Groskuhren Kleinkuhren, Kraxtepellen, Kreislacken and Hubnicken. Besides these works, there are other establishments at Brusterort, where amber is obtained by divers from the bottom of the sea, and at Schwarzort (near Memel) where it is raised by dredging for it at the bottom of the Curish Haff; the dredging establishment last-mentioned has been noticed at length in my Trade Report for the year 1866; its importance and size has of late years increased considerably, and at present about 80,000 lb. of amber are annually obtained by it.

The total amount of amber obtained during the year 1869 in all parts of the province of Prussia by the various means of collection, is estimated at about 150,000 lb., the value of which may be taken at 550,000 Prussian dollars. The quantity collected (by fishing for it) in the sea and upon the shore, is about equal to that raised by the digging and dredging works.

According to the opinion of competent persons, the produce of the diggings could be increased considerably by working them upon a regular mining system. Apart from the fact that no certain knowledge has hitherto been arrived at as to the actual extent of the amber fields in the blue clay, and these fields exist most probably not only in the vicinity of the seacoast, but also in the interior of the Samland, and even beyond that district and the frontiers of Eastern Prussia, it is most likely that below the stratum of clay to which the diggings are at present confined, there are other strata in which amber would be met with. This supposition is based upon the circumstance that considerable quantities of amber have been found amongst the soil washed away by the sea during heavy gales, from those portions of the coastal sand hills which lie below the layer of blue clay first alluded to.

The prices of the principal kinds of amber, as stated by an Official Report, vary according to the size, ranging from twenty-two Prussian dollars per lb. where the pieces run about nine to the pound to four dollars where the pound requires one hundred pieces or more. The prices of larger (so-called cabinet) pieces are subject to great fluctuations, and are fixed by the increase or decrease of demand from the East; the prices of the commoner kinds seldom vary more than about 10 per cent.

The chief seat of the retail amber trade is Dantzig; the wholesale trade is at present in the hands of only two or three firms in the province of Prussia. The working of the Prussian amber into mouthpieces, beads, etc., is likewise carried on chiefly at Dantzig, but also in all large cities; of late a manufactory of amber wares has been established at Polangen, a small Russian town near Memel, and it is intended to open similar works at Königsberg, Moscow, and at New York.

Sponges abound on the east coast of Crete, but the natives do not dive for them. This hazardous calling is pursued by Greeks from the islands of Symi, Calymno, and Khalki, who come yearly in numerous small craft, and purchase licences to fish for sponges. These duties are farmed, and the actual farmer is a Frenchman, who also fishes on his own account, and makes use of a small steamer and diving-bell to facilitate his operations.—*Consul's Report.*

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 2, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE POISON REGULATIONS CONTROVERSY.

THOUGH it is now some months ago since the late PRESIDENT expressed in anticipation his delight at the prospect that the pages of this Journal would be no longer encumbered by controversy on Poison Regulations to the exclusion of more valuable matter, and that contention in the pharmaceutical body would cease, still these desirable results have not been attained. Our columns instead of flowing with the milk and honey of pure pharmacy have been swamped with *débris* brought down by the poison-flood of the past six months. We have not even been able to avoid contributing editorially to the accumulation, and although correspondents declare themselves thoroughly tired of the controversy they still go on with it.

In addition to the letters which appear this week, we have received several others on the same subject which we refrain from publishing, partly because the writers in some instances request an exercise of editorial discretion, and partly because the other letters throw no new light on the subject.

While referring to this controversy, we will repeat the suggestion already offered last month, that the time for discussion is past, and we will now add the expression of our hope that the energies of pharmaceutists will be directed to other subjects, for the evening meetings of the approaching session will raise a demand for papers which can only be satisfied by them.

Before, however, dismissing the subject of poison regulations, we must mention that the proceedings relating to some recent cases of poisoning are striking illustrations of a very general ignorance of existing laws and regulations, not only among the public, but among magistrates, coroners, and the press. In one instance, a coroner expressed a hope that the next session of Parliament would produce an Act compelling druggists to label bottles in which they sold poison, and another suggests that arsenic should be sold coloured. These and analogous cases to which we have already referred seem to show that the public mind is foggy in regard to the measures by which protection against accidental poisoning is sought to be attained.

In addition to this, it would not be difficult to extract from recent cases of poisoning much evidence in support of the opinion long since expressed by one of the seniors of British pharmacy, that legislative protection against accidental poisoning is an impossibility.

ACCLIMATIZATION OF PLANTS.

THE introduction into our colonial botanic gardens of various economic plants has proved that many of them could be readily acclimatized, and so become valuable additions to the vegetable productions of their adopted land. We learn that in the Botanic Garden of Adelaide, South Australia, many foreign medicinal plants have been introduced, and are growing so well that there is now no doubt as to their adaptability for cultivation in that colony. Dr. SCHOMBURGK, the director of the Garden, says the demands by invalids for one or other of these herbs becomes more and more frequent.

The Madder (*Rubia tinctoria*) also grows so vigorously that, if it were not checked, it would spread in all directions and become a nuisance. Here, then, are instances of successful acclimatization of really useful plants. In France thousands of acres of land are devoted to the cultivation of Madder, and large profits are realized. We are all aware that it is one of the most important dye-plants known in commerce, so that, notwithstanding the heavy expense of freight owing to the great distance from Australia to Europe, it would no doubt prove a profitable crop for cultivation in Australia. Moreover the plant appears to require little or no attention during the progress of its growth.

PROFESSOR STOKES in his Presidential Address, delivered before the British Association, at Exeter, in 1869, referred to the artificial formation by MM. GRAEBE and LIEBERMANN of alizarine, one of the colouring principles of madder. Assuming that it might be possible to produce it at a sufficiently cheap rate, he instanced it as an example of the way in which the philosopher, quietly working in his laboratory, may obtain results which revolutionize the industry of nations, and also speculated upon the number of acres hitherto employed in madder cultivation that would be set free for the production of food or some other substance useful to man. Already there seems to be some verification of the soundness of his conjectures, for her Majesty's Consul in Cyprus reports that last year the demand for madder-roots grown in the island was limited with a corresponding fall of prices, and that this result is attributed by some persons to the influence of the discovery above mentioned. He adds, "Such a result, however beneficial to the world in general, would entail great loss to the owners of madder ground in Cyprus, which sells at as much as £70 an acre, while common grain-land can be had at £2 an acre."

The influence of forests upon the climate of a country, and the relation of the vegetation to the local peculiarities of a district, has often been observed. A fresh illustration is to be found in the Italian province of Oneglia, where for the last two years the olive crop has suffered from drought. It has been noticed that in recent years the rain that has fallen on this coast has been much less in quantity than formerly; and olive plantations, which were considered safe and lucrative property, are now looked upon as a bad speculation. The want of rain is generally attributed to the reckless way in which the mountains above the oil range have, especially of late years, been cleared of the forests which clothed them. From time immemorial the wood has been cut without any system of replantation; but, until about twenty years ago, there being no very great demand, and the mountains being utterly without roads, the quantity brought down to the coast was not large. Since that time the country has been opened up to a certain degree by roads, there has been an enormously increased demand for beech and oak for shipbuilding and chestnut for housebuilding, and some of the woods have been absolutely swept away without a tree being left. A society has been formed, having for its object to stop these reckless clearances, and to induce proprietors to replace, by degrees, the timber in those positions which do not allow of tillage.

Her Majesty's Consul at Santa Martha, New Granada, reports that although the cinchona bark shipped at that sea-port, and brought from the states of Tolima, Boyacá and Cundinamarca, is not so highly appreciated in European markets as that from the state of Cauca, known as Pitayo bark, and exported through the port of Buenaventura, yet its quality has of late greatly improved. The quantity exported from Santa Martha in 1869—amounting to upwards of 12,000 serons—was greatly in excess of any previous year, and nearly four-fifths of it was sent to England.

The cinnabar mines discovered in Borneo are now being worked by the Borneo Company. Retorts were erected last year, and a fair quantity of quicksilver obtained. The great difficulty of transport, however, enhances the cost of working very considerably. The antimony mines are also reported to be yielding good ore in fair quantities.

An association has been organized at Washington under the name of the Columbia Pharmaceutical Association. Some of the principal pharmacists of the city have taken an active part in its institution.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Tuesday Afternoon, August 1.

The Conference resumed at two o'clock; Mr. Stoddart, President, in the chair.

Dr. Attfield read the following paper:—

The Compound Iron Mixture of the Pharmacopœia.

BY C. A. STAPLES.

This has always been a favourite medicine, and, when carefully prepared, is perhaps one of the safest and most efficacious of the tonic chalybeate emmenagogues, and, consequently, it is the one most frequently prescribed, but it has always been exposed to the great objection that its extemporaneous preparation takes considerable time, and it cannot be kept ready for use as its character soon changes,—a few hours making a perceptible difference in its appearance, even if it does not in its medicinal efficacy. To remedy this defect, I endeavoured to prepare it in a concentrated form in two bottles. After a few experiments, I adopted the following formula, which I have used for a number of years, and the result has been so satisfactory as to leave nothing to be desired:—

℞. Gum. Myrrh. ℥ij
Potas. Carb. ʒj
Sp. Myrist. ℥viij
Aq. Rosæ ad ℥xx.

The myrrh should be very carefully selected,—clean pale pieces, presenting an opaque fracture being the best. Beat it as fine as possible in a large mortar, then add the carbonate of potash with a little rose-water and grind it to a smooth paste, gradually add about half a pint of rose-water to make a fine emulsion, add the spirit of nutmeg and as much more rose-water as will make it twenty ounces; preserve it in a stoppered bottle, labelled "Concentrated Myrrh Emulsion pro Mist. Ferri Co. ʒj to ℥j."

For the other bottle, boil 2 fluid ounces of distilled water in a glass flask; add ℥j of sulphate of iron, pure and free from oxide, dissolve and filter it into a 6-ounce bottle and fill it up with simple syrup, label it "Syrup of Sulphate of Iron gr. j in ♏vj, or ♏xv to each ounce of Mist. Ferri Co."

These preparations will be found very convenient; as for each ounce of the mixture, you have merely to measure ʒj of the emulsion and ♏xv of the syrup, dilute each with a portion of rose-water, mix and fill the bottle with rose-water, and mist. ferri co. of excellent quality is made in a few seconds.

Both preparations keep well; the quantity of spirit in the emulsion preserves it from decomposition, and it rather improves by keeping; and the syrup will be found to keep free from oxide, which the crystals rarely are, however pure they may appear to be; it may also be used for dispensing sulphate of iron in other mixtures, where the sugar is not an objection, for this purpose I make the above solution of ℥j of sulphate into an 8-ounce bottle of syrup, this gives one part of sulphate in eight measures of syrup, which I find more convenient for general dispensing, but it contains too much sugar for the mist. ferri co. as directed in the present edition of the Pharmacopœia.

The Chairman said that the quantities seemed to be very handy, and he believed it made a very good mixture.

Mr. Horncastle said he would like to know whether the emulsion formed in this way was as good as otherwise. He had not been so well satisfied with the appearance of the emulsion as when it was prepared at the time. He had found that sulphate of iron might be preserved with the greatest ease by avoiding putting it in a bottle. If it is put in a proper box, it might be kept in perfection for an unlimited period.

Mr. SCHACHT said that Mr. Horncastle had spoken of the difficulty of keeping the sulphate of iron free from change, and that it was less likely to change if kept in a box than in a bottle. That was a new idea, and he could scarcely have expected the result; but, of course, there was the well-known fact, practically more interesting, that a little piece of camphor put into the bottle prevented the change. He noticed that it had that effect; and if it was the case that a little bit of camphor prevented any change, it must be some chemical influence, and he should like to know if any gentleman could give an explanation of that which was a great mystery.

Mr. MATTHEWS said that as to keeping sulphate of iron in a box, he had not done so, but he had kept chemically pure sulphate of iron in a loosely-corked bottle, and it did not suffer any change in the course of five or six years. The cork had not been changed. He had not tasted it, but the colour was as good as when he received it.

Mr. WILLIAMS said he found that the crystals would keep for a considerable period when they were solid. There were certain kinds of sulphate of iron that would keep, and it was because of the density and solidity of the crystals, and did not depend upon the impurity of the metal.

Professor ATTFIELD said that many specimens of sulphate of iron made by the students came under his notice every year, and he found that when a solution gave single crystals those single crystals were always hard, and some that had no interstices between the plates would keep remarkably well. It was a fact, that the single crystals, the hard crystals, kept perfectly well; but with the masses of sulphate of iron they did not keep.

Mr. HORNCASTLE said that this subject had occupied his attention for some years, and he believed the presence of water, which was enclosed within the masses of crystals, was the source of difficulty.

Mr. ROBBINS was of opinion that the keeping qualities of the crystals depended on their hardness and freedom from water, mechanically retained in thin interstices; and mentioned as an example that he had a natural crystal of large size, which was kept in a glass case for some years, showing scarcely a trace of oxidation.

REPORT ON THE PERMANGANATE OF POTASSIUM OF PHARMACY.

BY ALFRED H. ALLEN, F.C.S.,

Lecturer on Chemistry at the Sheffield School of Medicine, etc.

Permanganate of potassium occurs in the form of prismatic crystals, so deep in colour as to appear black, with brilliant coloured reflections. The crystals are anhydrous, permanent in the air, and soluble in about sixteen parts of cold water. The solution is neutral to test paper and a most powerful oxidizing agent, organic matter being rapidly turned brown by the reduced salt.

The amount of real permanganate was estimated by dissolving the salt in 500 parts of distilled water, and deoxidizing it by an accurately measured quantity of oxalic acid solution of known strength, the liquid being acidified with sulphuric acid. This is the ordinary method of determining the strength of solutions of permanganate, and is rapid and accurate.

The oxalic acid solution at first employed contained 63 grammes of the crystallized acid in 1000 grammes of distilled water. In the latter experiments a solution of half this strength was used.

Five atoms of oxalic acid are deoxidized by two atoms of permanganate, therefore 630 parts $H_2C_2O_4 + 2aq. = 316$ parts $KMnO_4 = 80$ parts available oxygen.

No. 1 was a sample of crystallized permanganate of potassium obtained in Sheffield. It was dissolved in 500 parts of water, and decolorized with the standard oxalic acid, of which 10 c. c. were oxidized by 163 c. c. of the permanganate. These numbers correspond to a percentage of 96·93 of pure permanganate.

No. 2 sample was bought in Newcastle-upon-Tyne. The crystals were larger than those composing No. 1, and it was chosen as the best of several specimens. The mean result of the analyses showed a percentage of potassium permanganate of 98·87.

No. 3 had been in the possession of the author nine or ten years, and was purchased in London. It contained 93·55 per cent. of real permanganate.

Following are the tabulated results of the examination of the above three samples:—

	No. 1. Per cent.	No. 2. Per cent.	No. 3. Per cent.
Real $KMnO_4$	96·93	98·87	93·55
Available Oxygen . . .	24·54	25·03	23·69

All three samples contained traces of sulphate, but no chloride. On solution in water they left a small quantity of a heavy, dark-coloured residue. That from No. 3, which was largest in quantity, dissolved in oxalic acid with effervescence, and the solution, rendered alkaline with ammonia, gave a brownish precipitate with potassium ferricyanide, proving the residue to have been manganese dioxide. The residues from Nos. 1 and 2 seemed similar.

The liquor potassæ permanganatis of the British Pharmacopœia contains 80 grains of the salt to the pint of water =

$KMnO_4 = 0·9143$ per cent.
$= 9·143$ grammes per litre.
= Available Oxygen 2·315 „ „

A sample of Condy's Crimson Disinfecting Fluid had an oxidizing power equal to—

$KMnO_4$ 1·550 per cent.
$= 15·50$ grammes per litre.
= Available Oxygen 3·921 „ „

A specimen of Condy's Green Fluid had almost as great an oxidizing power as the crimson. The active oxygen of an equal number of atoms of manganate and permanganate is as 4 : 5, and the atomic weight of the former salt being higher, gives the calculated amount of manganate of potassium in the green fluid as—

$K_2MnO_4 = 24·0$ grammes per litre.
= Available Oxygen 3·883 „ „

The oxidizing power of the green fluid is not entirely due to manganate, as a small but variable amount of permanganate is always present. This may be detected by precipitating the manganate with barium chloride and filtering through asbestos, when the crimson colour of the permanganate becomes apparent.

A qualitative analysis proved the crimson fluid to contain much sulphate, evidently due to the sulphuric acid employed to neutralize the excess of alkali in the crude product. The green fluid was strongly alkaline, the crimson nearly neutral. In other respects they were similar.

It was not thought requisite to examine a larger number of specimens of permanganate, as inquiry proved it to be of limited application in pharmacy, and the above results showed that *the crystallized salt was practically pure.*

Dr. ATTFIELD read a paper on—

USE OF BLISTERING FLIES IN HYDROPHOBIA.

BY HENRY GROVES, OF FLORENCE.

The paper on Chinese blistering-flies by Dr. F. Porter Smith, recently published in the *Medical Times and Gazette*, mentions the employment by Chinese practitioners of blistering insects in cases of hydrophobia; and as I am not aware of the remedy being similarly used in

Great Britain, it seemed to me that further attention should be paid by qualified men to a medicine which has a certain repute in several parts of Europe for curing the bites of mad animals. Dr. Grisanowski, of this city, kindly informed me of its use in Russia and France, and has supplied me with information on the subject. It appears that about thirteen or fourteen years ago a certain Nikititsch Levachoff, of Peklitz (Government of Riazan, Russia), created a sensation by his cure of hydrophobia. His arcanum was supposed to be the *Cetonia aurata*, or rose beetle. The monks of Phaneromenos, near Eleusis, Greece, use the insect *Mylabris bimaculata*, with equal parts of the leaves of *Cynanchum excelsum*, in doses of 15 grains of the mixed powder; at the same time they cauterize the wound with boiling oil. The physician of the late King Otho, of Greece, often gave half-grain doses of cantharides, until symptoms of incipient gastro-enteritis declared themselves. Here in Tuscany there are one or two persons who are reputed to be able to treat successfully the bites of mad animals by means of a nostrum whose basis is supposed to be cantharides, or other insects with blistering properties; and it appears that their efforts are not unavailing, inasmuch as a medical man, to my knowledge, was convinced of the efficacy of the remedy, and caused a number of bottles to be prepared by one possessing the secret, and forwarded them, with a memoir, to the Academy of Medicine at Paris. As the box containing the remedy must have arrived at its destination but a short time before the breaking out of the recent war, it is probable that the whole matter has been set aside and forgotten. Speaking of the remedy to the physician, I suggested to him that it contained cantharides, to which he assented, or supposed that at least some blistering fly entered into the composition; and it then occurred to me that I had once copied an ancient recipe for hydrophobia, and that out of curiosity I had retained a copy for myself. Probably the two compounds are identical. The formula in my possession was represented as a secret left by S. Donnino to the family of Boccaccio, and is represented by the following translation:—

Secret for Curing the Bites of Mad Dogs.

Take of cloves, grains 54
cinnamon, grains 54
pepper, 1 drachm and grains 36
cantharides, grains 27. Mix.

Dose according to age:—
From 25 years and upwards, grains 26
For 12 years, grains 19
10 years, grains 14
4 years, grains $6\frac{1}{2}$
2 years, grains $3\frac{1}{2}$

It may be taken from the day of the bite up to twenty-five days after. The remedy must not be administered to pregnant women. It is to be taken in one dose according to age, as marked above, in wine, broth or water, according to the taste of the sick person. It must be administered fasting, and the patient should not eat anything for at least four hours, and during this time should take a great deal of exercise, in order that the remedy should act the more. The patient will suffer strong pains in the head and kidneys, besides other inconveniences; even to the passing of bloody urine, should the dog have been really mad, and the blood have commenced to be contaminated. If at the height of the pain the patient would like to drink a glass of Nocera or Lettuccio water, it will serve him as a relief.

Remarks.—Tuscan grains have the value of 5 centigrams; consequently are less than the grain employed in Great Britain, Germany, etc. Nocera water is derived from a source in the Central Apennines, and Lettuccio water is the produce of one of the springs at Montecalino in Tuscany. It has laxative properties, and is less nauseous than many other purgative waters.

The *Cantharis vesicatoria* is found in several parts of Tuscany, its chief source being the Val di Chiana, where the peasants collect it by spreading cloths under the trees morning and evening, and shaking the insect out of the branches. The months of May and June are those in which the gathering takes place, and the fly prefers the Olive-tree to the Poplar and Ash, which they also frequent. They are killed by being plunged into weak vinegar, or by being held over the steam of the same. Afterwards they are dried as rapidly as possible in the sun, and are frequently turned over by a thickly gloved hand, or by other means.

The Chairman said that if he were bitten by a mad dog, he would not like to trust to the remedy here proposed.

Dr. Attfield read a paper on—

Solutions.

BY T. B. GROVES, F.C.S.

A short discussion that ensued on the reading, before the Pharmaceutical Conference at Liverpool, of Mr. Rimmington's paper on "The Specific Gravity and the Actual Weight of Certain Volume Measures of Various Liquid Preparations," set me inquiring on the subject of the volume occupied by salts when dissolved in water.

The statement credited to the President by the reporter of the Pharmaceutical Journal is to this effect, "That the contents per oz. were coincident with the specific gravity; for instance, lemon-juice having a sp. gr. 1·040 would contain 40 grs. of citric acid per oz., and so on, except in such cases as alum and sulphate of soda, where there is much water of crystallization. In those cases it would be half, or 20 grs. per oz."

Mr. Reynolds followed with the remark, that the same rule applied to sugar in diabetic urine, but properly qualified the assertion by the phrase "roughly speaking."

In the cases of both lemon-juice and urine, the estimation by that method must necessarily be exceedingly rough, as the variations in the proportions of other constituents affecting the specific gravity of the fluids are left out of the question entirely.

Although I have no new experiments to offer, I shall, I think, be doing some service, if I recapitulate shortly the facts I have ascertained in the course of my recent reading on this subject. It will, at least, serve to caution some who otherwise would be inclined to place too implicit reliance on the "rough methods," already referred to.

Dalton, during the latter part of his life, occupied himself with the question of solution, and derived from his experiments this supposed law, "that when a body dissolves, it will only increase the volume of the solvent in proportion to the water of crystallization it contains." His method of research involved the use of two measuring vessels, and pouring backwards and forwards, in fact, was quite incapable of giving accurate results.

This, as well as the want of general applicability of his laws, was pointed out by Hilton, whose voluneno-meter, consisting of a glass flask with a long, narrow, graduated neck, enabled the experimenter to approach more nearly to accuracy of determination. He found that whilst the theory approached correctness in the cases of desiccated sulphate of magnesia and carbonate of soda, it completely broke down in the cases of the naturally anhydrous salts, nitrate of potash, sulphate of potash, etc.

Walker found, to his astonishment, sometimes an expansion, sometimes a contraction of the whole volume of salt and water, according to the nature of the salt employed, and the strength and temperature of the solution. However, he does not appear to have commenced with very clear notions, for after repeatedly employing the terms "bulk" and "volume," he goes on to say, "I next proceeded to determine if the increase of volume had any relation to the specific gravity of the different substances, or if, when a known weight of salt was dissolved in water, the increase of volume was in proportion to the volume, as indicated by the specific gravity, and if so, the salt would dissolve without either expansion or contraction." Did he really expect an ounce of sulphate of magnesia, for instance, to occupy the same space as an ounce of water!

This method involved the use of a volumenometer. The one employed was not so well adapted for the attainment of accurate results as that of some other experimenters, but was, on the whole, far superior to that of Dalton.

Nitrate of potash was the first salt employed in testing the value of his new idea. The specific gravity of nitrate of potash being, according to his determinations, 2·074, one hundred grains of the salt would occupy the space of 48·21 grains of pure water. The calculated specific gravity would therefore be found thus,—100 grs. of salt being dissolved in 500 grs. distilled water—

$$\frac{100 + 500}{48{\cdot}21 + 500} = \frac{600}{548{\cdot}21} = 1{\cdot}0944.$$

But the specific gravity ascertained by experiment was 1·1100, showing, according to him, a condensation amounting to 6·22 grain measures.

I certainly cannot deduce this amount from the data given, but make it 7·7 gr. m. However, the principle being established, it becomes possible when the ratio of condensation of a salt is known, to calculate the specific gravity of a solution within certain limits of accuracy—those limits being defined by temperature and degree of dilution.

The effect of dilution as exemplified in the case of a saturated solution of nitrate of soda is shown to be the following:—

If to 430 gr. m. of a saturated solution 60 gr. m. of water be added, the mass will suffer a decrease of volume of 1 gr. m. Sulphate of magnesia behaves in the same manner, and to the same degree. Nitrate of potash suffers a diminution of ·5 gr. m., muriate of ammonia ·25 gr. m. under the same circumstances.

From a long and laborious paper by Messrs. Playfair and Joule, describing a series of experiments undertaken in order to ascertain whether there really existed any similarity between solid and gaseous combinations, in respect of the law of equal or multiple proportions observed first by Gay-Lussac in the case of gases,—I propose to select those facts only that seem to have some pharmaceutical interest, and are possibly capable of practical application, omitting reference to the theoretical deductions therefrom further than to say that they have since been roughly handled by Professor Marignac, of Geneva, whose criticisms appear to me to well deserve consideration.

The volumenometer employed differed from that used by Holker, in that it had a tubulure in its side for introduction of salt, fitted with a ground-glass stopper. This admitted of the stem being of smaller diameter, and enabled the experiments to be attended with greater accuracy.

Unfortunately, however, the experimenters, whilst acknowledging the disturbing effects of temperature and dilution, seem to have adopted no systematic method of procedure as to the one or the other, unless it be true that the particular temperatures and dilutions adopted were selected because the results so obtained accorded best with certain theories sought to be established. This Professor Marignac evidently points at, though he does not actually affirm it.

I may mention the case of sugar as being especially interesting to the pharmaceutist. The volume occupied by an equivalent of this substance = 172 grs., varies according to dilution between 99·00 and 108·06 grm., as follows:—

Ratio of Sugar and Water.	Temp.	Vol. in gr. m. of 172 gr. Sugar.
1 : 20	60	99·00
1 : 10	52	105·09
1 : 1	52	107·01
3 : 1	52	108·06

The temperatures here even are not uniform. I may observe that when the ratio is 1 : 1, the sugar occupies a volume very nearly co-incident with that due to its specific gravity 1·606.

The investigation included the determination of a vast number of specific gravities and solution volumes of salts of every description. In compiling the following table I have selected a few only of special interest, considered pharmaceutically. The specific gravities are, in general, not those of Playfair and Joule, but those obtained by H. Buignet through the use of the Air Volumenometer invented by Regnault; and therefore, I consider, more worthy of acceptance. The term "specific gravity in solution," I employ simply to designate the weight of the solvend in air divided by the space it occupies in the solvent:—

Name of Salt.	Sp. Gr. in Air.	Sp. Gr. in Watery Solution.
Sulphate of Copper	2·302	2·77
" Soda	1·471	1·76
Biborate "	1·692	2·085
Chloride of Calcium	1·68	1·98
Potash Alum	1·757	2·135
Ammonia	1·653	2·00
Carbonate of Soda	1·463	1·58
Sulphate of Magnesia	1·675	1·96
" Iron	1·902	2·22
Nitrate of Potash	2·126	2·80
" Soda	2·265	3·22
Chloride of Potassium	1·986	2·80
" Ammonium . . .	1·55	1·50
Bromide of Potassium	2·65	4·10
Iodide "	2·97	3·77
Chloride of Sodium	2·145	3·21
" Barium	3·081	4·42
Chromate of Potash	2·68	5·60
Bichromate "	2·624	3·35
Carbonate "	2·10	7·54
Bicarbonate "	2·18	3·00
" Soda	2·165	4·70
Oxalate of Ammonia	1·47	2·00
Sugar	1·606	1·608

Bearing in mind the irregularity that seems to attend all bodies, and mixtures of bodies, on the verge of change of state, and, therefore, confining oneself to solutions of mean condition, neither extremely strong nor excessively weak, it is possible by means of this table to ascertain beforehand, with tolerable accuracy, the effect of mixing definite quantities of a salt and water, and *vice versâ* of determining the proportions of both salt and water necessary to produce a given specific gravity. Thus taking the case of sugar,—what will be the specific gravity of a solution containing equal parts of sugar and water? The volume of the water will, of course, be 1, the volume of the sugar $\frac{1}{1{\cdot}608}$, the total volume being 1·6218. Dividing the total weight = 2 by this, we get the specific gravity = 1·23. According to the table in Watts' 'Dictionary,' the specific gravity of a solution containing 50 per cent. of sugar is 1·2166 at the temperature 63·5°. Proceeding in the same way with chloride of sodium, we get for a solution containing 20 per cent. of salt the theoretical number 1·159, the experimental number being 1·1511.

Sulphate of magnesia gives for a 30 per cent. solution

1·172 theoretically, 1·1536 experimentally, the temperature in the latter case being 72·4° instead of 60°, which accounts, doubtless, for the comparatively large discrepancy. A solution of specific gravity 1·72 would, at that temperature, contain 33·5 per cent. of salt.

To determine the necessary proportions of salt, or other soluble substance, and water in order to produce a given specific gravity is not quite so simple. In order to avoid having two unknown quantities, we will assume the quantity of water to be known. Let it be 10. It is required to ascertain the quantity of sugar necessary to produce with that amount of water a syrup having the specific gravity 1·20. The specific gravity of the water is, of course, 1·00: the specific gravity in watery solution of sugar 1·608. The symbol x represents the unknown quantity we have to ascertain. Then

$$\frac{10}{1} + \frac{x}{1 \cdot 608} = \frac{10 + x}{1 \cdot 2} = 7 \cdot 89$$

i. e. to produce a syrup of specific gravity 1·20, 7·89 parts of sugar must be added to every 10 parts of water. Such a syrup ought theoretically to contain 44·1 per cent. at 60°. According to the table in Watts' 'Dictionary,' a syrup of specific gravity 1·2057 at the temperature 63·5 should contain 45 per cent. of cane sugar.

The theoretical considerations involved in the phenomena of solution are so numerous and interesting, that I propose some day to resume the subject I have now merely scratched on the surface, as it were; in which case I will ask again to be permitted to bring the subject before the notice of the Pharmaceutical Conference.

The Chairman said that this was a very interesting paper, and confirmed some of the views he held on the same subject.

Preservation of Meat.

Dr. Paul, F.C.S., said he was surprised to find himself put down as announced to read a paper on the preservation of meat. He had no intention of doing so, and all he had to give was a merely verbal narrative as to a new method of dealing with meat, which he had recently had an opportunity of studying. Every one present would be aware that in the only successful mode of dealing with South American meat,—in the preparation of Liebig's extract,—the great mass of the feeding portion of the meat was wasted; in fact, instead of producing food, they merely produced a material which was a kind of stimulant, the whole of the fibrine and albumen being lost. Some experiments had been made by the inventor of a process to which he would now refer, with the object of drying the meat by pressure; and he had found, what a great many other people had found who had endeavoured to express from any organized structure the water or liquid it contained, that he could only succeed very imperfectly. However, Mr. Henley, the inventor of this method, had, by submitting meat to hydraulic pressure, succeeded in removing from it about one-half of the juice contained in the tissue. That juice was a liquid containing the constituents of the ordinary extract of meat made on Liebig's plan of infusing the meat in water, and it also contained all the soluble albumen. Its specific gravity, as it ran from the hydraulic press, was about 1030, and it yielded on evaporation about 8 per cent. of a perfectly dry residue. Of that residue, five parts out of the eight were albumen; and if the juice were heated up to about 100°, to coagulate the albumen, they got a pale liquid which might be boiled down, and then gave as residue the ordinary extract of meat. Another plan of dealing with this expressed juice was to evaporate it at such a heat as would not coagulate the albumen, and adding a small quantity of gelatine: it could then be converted into portable soup, put into bladders and preserved in that condition for a great length of time. But the principal object of the process was to deal with the residual pressed meat, from which half the juice and half the water had been expressed, and also about half the soluble albumen and other constituents contained in the ordinary extract of meat, so that the residual pressed meat was actually richer in nutritive constituents than the original meat. If this pressed meat were submitted to further drying by heat, it might be reduced to a state in which it would contain about 10 per cent. of moisture, and meat in that state would keep for almost any length of time. He had hoped that he might have had some samples sent down in order to let the members see what could be done with these products. There were three products—the dry beef, the prepared beef-juice and the ordinary Liebig's extract.

The Chairman said he thought that the system of preserving meat explained by Dr. Paul, if it would really keep a long time, was likely to be a very valuable one. It was supposed that Liebig's extract, of which so much was sold, was really a feeding commodity, whereas it was not so, but it acted as theine acted in tea,—it prevented waste of tissue, and consequently was rather stimulating than nutritious. But in the plan referred to by Dr. Paul, where you have still 50 per cent. of the *extractum carnis*, combined with all the nutritive ingredients of the meat, the product has more the character of a true animal food.

Mr. Hanbury (London) said that this reminded him of a subject which was brought up at a meeting of the Royal Society of London a few weeks ago, when Dr. Simpson took occasion to remark that at a large London hospital with which he was connected the beef tea was prepared so as to contain almost the whole of the solid matter of the meat. The beef was first infused, and then the meat that had been used the previous day, and from which the infusion had been strained off, was reduced to a sort of pulpy state, and mixed with the fresh infusion. It was stated that this plan produced most excellent results, and it had been in vogue for some years, to the general satisfaction of the medical officers and of the patients.

Mr. Deane (London) said he had had some experience in regard to Liebig's extract of meat. He found that after separating the matter which was soluble in water at a temperature which would coagulate the albumen, the residue was left in a very insoluble and indigestible state. He had come to the conclusion that meat fibre that had been deprived of the phosphates and chlorides that were held in the juice of the meat among the fibres could be of no manner of use, and he should therefore infer that the meat prepared by pressure, from which half the soluble salts had been removed, would be a very indigestible substance. Liebig's extract was a restorative under certain conditions, but it would be a mistako to suppose that it possessed all the nourishment of the meat from which it had been taken. When any of them found themselves exhausted, it was because the muscular system was deprived of some of its constituents, and it was a remarkable fact that when a person was so exhausted, if he got a small quantity of Liebig's extract, say half a dram in hot water, in the course of ten minutes a wonderful restoration took place. He had a suspicion that if they had the pressed meat referred to, with half of the matter removed, it would be ill for weak stomachs like his own, which required a little more of the extract. These were the chief points which he had to mention. He had paid a great deal of attention to the process, and he had instructed a gentleman who went out to the Australian Meat Company as to the proper method of preparing the extract. That gentleman went and carried out his (Mr. Deane's) instructions very generally, and the result had been very successful. In regard to cooking, there was no necessity for boiling meat or fish rapidly; for if a little time were allowed there would be better results.

Mr. Savage (Brighton) said that this subject had been under consideration for the Sussex County Hospital. The extract of meat had been used there, and it seemed to answer uncommonly well.

Professor ALLEN said he could endorse the remarks that had been made as to Liebig's extract being a stimulant. He had taken it in a glass of wine and it had a restorative effect. Some people objected to the flavour of it, and some said it had a burnt taste. He could not say that it had that taste; but he used plenty of pepper with it. He thought that the preparation of meat sold by Fortnum and Mason, Piccadilly, was uniformly prepared. It was in the form of a sausage, which was enough to make a basin of soup.

Mr. ATKINS said he had recently observed one or two striking cases of the nutritive quality of Liebig's extract. He had found that slices of toast covered with Liebig's extract were more effectual as a restorative than anything else he was aware of. He would like to know whether the opposition of the faculty to Liebig's extract was gradually yielding. There was an opinion among medical men that it was deficient in some of the important qualities required in beef-tea.

Mr. MACKAY (Edinburgh) said he could bear testimony to the value of Liebig's extract when made into beef-tea. Several very striking instances of its value had come under his own observation; and, at this moment, there were two persons he had in view who had derived great benefit from it. One was a lady advanced in life, and the other a young man, both given up by their medical men, and they were about to sink from sheer want of nourishment. They had taken a dislike to everything that was named to them, and at length it was suggested to them that they should take Liebig's extract, from which they got the greatest advantage. He had often heard medical men speak of the stimulating and nourishing effects of the extract. He had known cases of gentlemen who were out on the moors, and by spreading a biscuit or toast with the extract, it had enabled them to go through almost any amount of fatigue.

Professor WRIGHT said that the prevailing opinion was that the extract did not do so much to prevent muscular waste as to enable the digestive organs to act more perfectly on the food materials and cause less waste than would be the case were the semi-alkaloids not present.

Mr. COLLINS (London) said that a friend of his travelling in South America never went out without Liebig's extract; and when he was exploring there was nothing which gave him so much strength. He was sometimes days without any other food whatever.

Mr. SCHWEITZER (Brighton) said he had made some beef powder. It had the same appearance as coagulated albumen, and nothing would soften it.

Dr. PAUL then replied. He said that as to the preparation of Fortnum and Mason, he believed it was a kind of portable soup, made by partial evaporation of beef juice and the addition of a little gelatine. It was not his intention to speak of meat extract as a stimulant. Taking small quantities of extract of meat when a person was working hard might for a time sustain him, but that was no proof that it was food. He might be living on his own body. It was true that the pressed meat was not to be compared with a fresh beefsteak, but that was not the question at all. All meat-preserving methods were intended to utilize a quantity of meat that would not otherwise be used. It had been pointed out by Liebig that one of the greatest defects in preparing his extract was that it left the great mass of the animal utterly worthless. It required thirty pounds of beef on the average, and of the better parts, to produce one pound of the extract, and the other twenty-nine pounds were entirely waste. The real way of considering the method he had brought under their notice was to compare it with the other methods intended to attain a similar result. It might well be that since the pressed meat contained less of the juices than fresh meat, it might be less digestible and less valuable as food, but that was still more the case with salt junk. He thought that this new method of dealing with meat was one worth attention and observation, whatever might be the actual nature of the results.

PROTECTION TO BOTTLERS.

Mr. BAILDON (Edinburgh) then exhibited a guard to be put upon bottles, for the protection of men engaged in bottling aerated waters. He had no doubt this ingenious contrivance by Mr. Fraser would be interesting. It was a very efficient protection to the bottlers, who often had their hands and arms severely cut. He had had practical experience of the plan himself, and he could say that it was very simple and afforded very efficient protection.

The Conference adjourned at four o'clock, to meet next day at eleven.

Wednesday, August 2.

The Conference met on Wednesday morning at eleven o'clock; Mr. STODDART presiding.

Mr. HANBURY read a paper on—

THE CRYSTALLINE PRINCIPLES IN ALOES.

BY DR. F. A. FLÜCKIGER,

Professor of Pharmacy and Pharmacognosy in the University of Bern.

A large sample of *Natal Aloes*, a variety of the drug remarkable for its opacity and pale tint has been presented to me by my friend Daniel Hanbury. Thin fragments of it are so little translucent as to show but a faint brown colour. The fracture of large lumps exhibits a dense conchoidal surface of a dull greyish brown or drab, marked with a few yellowish veins, and quite devoid of the brilliant vitreous gloss exhibited by newly broken Cape aloes.

Fragments freely moistened with spirit of wine, when examined microscopically especially in polarized light, are seen to consist of numerous crystals imbedded in a yellowish amorphous mass which is readily soluble. Mr. Hanbury first observed that the crystals on the other hand are but sparingly soluble and that when the crude drug is treated with spirit of wine they separate as an almost whitish deposit; he consequently suggested they might be something different from aloïn. These crystals as they occur in Natal Aloes, are not well defined; most of them are thin, short prisms, sometimes tufted, as in aloïn from hepatic Aloes. Sometimes also single, tabular, probably rectangular crystals are met with, as may be seen by gently crushing a fragment of the aloes with glycerine between two glass-slides.

There is no difficulty in separating the crystals from Natal Aloes. If the drug is rubbed with an equal weight or a little less, of spirit of wine at a temperature not exceeding 120° F., the amorphous portion of it is dissolved. The remaining crystals may be collected on a filter and washed with a small quantity of cold spirit. From 16 to 22 per cent. of crude pale yellow crystals can thus be got.

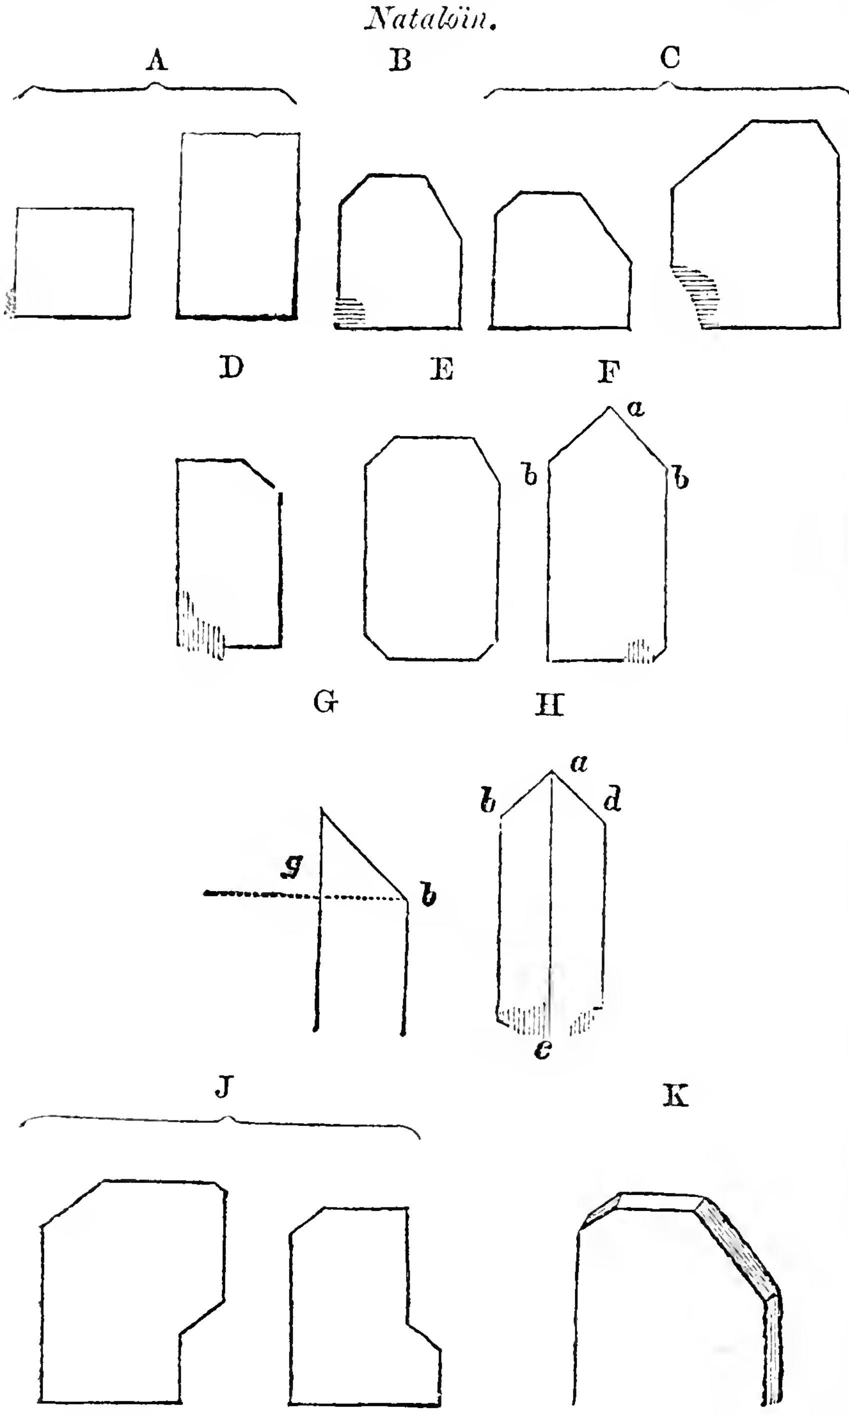
The difficulties begin when the purification of the crystals has to be effected. For this purpose I have tried the usual solvents without discovering any liquid that is thoroughly convenient for dissolving my *Nataloïn*, for by this name I propose to designate the substance. Neither water, benzol, bisulphide of carbon, petroleum-ether, chloroform, or ether, is capable of dissolving nataloïn in appreciable quantity. A mixture of ether (1 part) and spirit of wine (3 parts) succeeds a little better; the same may be said with regard to anhydrous aceton, methylic and amylic alcohol, glacial acetic acid and acetic ether. After all however, I do not feel convinced of the advantage of any one of those solvents over common spirit of wine, of which 70 parts dissolve at about 60° F., one part of nataloïn, or of the above-named mixture of ether and spirit, 60 parts; while of methylic alcohol 35 parts, of acetic ether 50 parts, of ether 1236 parts and of absolute alcohol 230 parts, are respectively required for dissolving one part of nataloïn.*

Nataloïn in small crystals is rather more intensely yellow than flowers of sulphur; larger crystals display a somewhat orange tint. Its taste is pure bitter, neither a sweetish nor an acrid after-taste being observable.

In warm or hot spirit of wine nataloïn is scarcely more soluble than in cold. By heating the liquid even gently, it quickly turns darker, assuming a red colour, so that some decomposition is evident, nor can it be wholly avoided by evaporation *in vacuo*. The best method of recrystallizing seems to be that of heating the nataloïn with 60 or 70 parts of spirit of wine to 100–120° F., and allowing the solution thus obtained to evaporate spontaneously during several weeks; in this way may be got crystals of $\frac{1}{3}$ to $\frac{1}{2}$ a millimetre long.

The crystallographic features of nataloïn are very characteristic. The small, first-deposited crystals as well as the larger ones, always consist of extremely thin and brittle scales, not resembling the crystals originally found in the drug. The most perfectly developed crystals of nataloïn are square, or at least rectangular scales (A),

Nataloïn.



A crystallised from absolute alcohol.
B, C, D, E, F, J from spirit of wine, slowly grown.
G, H quickly separated from spirit of wine.
K from acetic ether.

but two of their angles are usually more or less truncated (B). The amount of truncation of the angles is usually not the same on both sides (C), and is even sometimes restricted to one only (D). Crystals having all their four angles truncated are rarely met with (E), and pointed scales like F are still more exceptional.

Nataloïn which has been quickly deposited from a warm alcoholic solution shows a predominance of the form indicated in fig. G, and sometimes also in fig. H which is striated lengthwise. The latter seems therefore to be rather a combined figure than an individual crystal.

If the scales H are examined in polarized light, the two parts namely *a b e* and *a d e* are sometimes manifestly different in the direction of their refracting power,* which in nataloïn is always very brilliant. Finally there are also found irregularly developed crystals (J).

The crystals of pure nataloïn being usually so small, their angles can only be measured approximatively by means of the micro-goniometer. Some estimations not quite satisfactorily ascertained, furnished me 82° for the angle *a* and 139° for angle *b*. The crystals are easily broken according to their longitudinal direction, *a e* for instance in fig. H, yet still more so in a direction parallel to their surface. If an alcoholic solution evaporates very slowly, tabular crystals of appreciable thickness can be obtained, yet in a less pure state. If they happen to be a little injured, their longitudinal edges exhibit a distinct lamellar structure as shown in fig. K. Crystals of this kind are chiefly formed from a solution in acetic ether. An alcoholic solution yields mostly regular square scales.

Nataloïn gives off no water when exposed over concentrated sulphuric acid or when heated to 212° F., in either case even for some days; and this behaviour shows at once that it is not identical with the aloïn discovered by Messrs. Smith of Edinburgh and examined by Dr. Stenhouse. According to this chemist, crystallized aloïn parts with 2·69 per cent. of water when dried over sulphuric acid, and entirely loses its crystalline aspect when kept for some days over a waterbath. Nataloïn is not even altered or its weight diminished if it is heated to 284° F. Decomposition begins to take place only towards 320° F. when the nataloïn turns greyish; the temperature named having been maintained for many hours, the loss of weight amounted only to 3·8 per cent. At 356° to 374° F., nataloïn fuses becoming previously of a dark, brown red, but it is still partially crystallizable as may be ascertained by treating it with solvents.

Nataloïn is soluble in concentrated sulphuric acid; the orange liquid yields a precipitate by addition of a small quantity of water, but the dingy colour of the nataloïn so obtained probably shows that partial alteration has taken place. If the vapour of fuming nitric acid is cautiously directed on to a solution of nataloïn in sulphuric acid, the latter acquires a fine green colour, quickly changing to red and blue. This very intense and distinctive reaction which was first pointed out by Mr. Histed, may be illustrated as well by rolling a crystal of saltpetre in the sulphuric solution. A small grain of chlorate of potassium produces a brilliant green zone, almost instantaneously disappearing. Nitrate of bismuth gives nearly the same effect. Bichromate of potassium acts in a similar manner as with strychnine only that the colour is less pure. *Natal aloes* being so rich in nataloïn, itself displays these reactions by which in fact, it may be easily *distinguished from* the *aloes* of the *Cape, Zanzibar* or *Barbados*.

By heating nataloïn with nitric acid of about sp. gr. 1·3, to 140°–160° F., a red solution is obtained which at length turns yellowish as the nataloïn slowly disappears. But I have not been able to discover in this liquid either picric or chrysamminic acid, yet the latter according to

* Mr. Edward Histed of London who has been occupying himself also in the examination of Natal Aloes considers methylic alcohol to be by far the best solvent for nataloïn.

* This however may quite as well be due to the occasional superposition of extremely thin scales.

Stenhouse is formed when aloïn and nitric acid are heated together. Nataloïn yielded me only oxalic acid.

I have made five analyses in order to ascertain the elementary composition of nataloïn. By burning it in a current of oxygen—

I. 0·2025 gramme yielded 0·4380 carbonic acid and 0·1125 water.

II. 0·2450 gramme yielded 0·5325 carbonic acid and 0·1372 water.

III. 0·2288 gramme yielded 0·5135 carbonic acid and 0·1215 water.

IV. 0·2605 gramme yielded 0·5578 carbonic acid and 0·1395 water.

V. 0·1598 gramme yielded 0·3525 carbonic acid and 0·0898 water.

These results answer to the following percentages:—

	I.	II.	III.	IV.	V.
Carbon .	58·99	59·14	61·18	58·38	60·15
Hydrogen	6·17	6·24	5·92	5·95	6·24

The average numbers of these would be

Carbon	59·56
Hydrogen	6·10

The crystals analysed were taken from different crops and dried at 212° F., except those burnt in analysis V. The latter were the purest and largest crystals I have ever obtained; I dried them some days over sulphuric acid, and then exposed them to 212° F. only for a short time. The analysis of these crystals appears to me, on the whole, to be the most trustworthy; its results would lead to the formula $C_{34}H_{38}O_{15}$, viz:—

34 C	408	59·47
38 H	38	5·54
15 O	240	34·99
	686	100·00

Both the analysis V., as well as the general average agree tolerably well with this formula. Now the same formula is assigned by Stenhouse to his crystallized hydrated aloïn. Deprived of the molecule water H_2O, anhydrous amorphous aloïn of Stenhouse contains carbon 61·07, and hydrogen 5·39, with which only my analysis III. would agree. There is, however, one fact perhaps, which might speak in favour of the *higher* percentage relating to carbon,—that is the composition of the *drug* itself, which I found to be *less rich* in carbon than its crystalline principle. I submitted 0·2645 gramme of Natal aloes (dried at 212° F.) to elementary analysis equally by means of oxygen, and obtained 0·5365 carbonic acid and 0·1385 water. The drug consequently contains 54·63 per cent. of carbon and 5·80 of hydrogen.

Stenhouse in assigning the above formula to crystallized aloin, or rather $C_{34}H_{36}O_{14}$ to the anhydrous aloïn, was well entitled to do so by the existence of the crystallized bromine compound $C_{34}H_{30}Br_6O_{14}$, which he discovered. Yet as to the nataloïn, I have failed to obtain a well defined bromine compound. If bromine is added to nataloïn, heat is evolved and bromine evidently absorbed. The orange mass then proves much more readily soluble in spirit of wine than nataloïn, and also in methylic alcohol; but the solutions yield no crystals, either by slow evaporation, or on addition of water. I further enclosed in a sealed tube nataloïn with a sufficient quantity of bromine and heated the tube for many days at 212°, but notwithstanding the partial absorption of the bromine, this method too proved not more satisfactory. I have, therefore, not further examined the bromine compound. Iodine appears to be incapable of uniting with nataloïn.

Some crystallized compound or well defined product of decomposition of nataloïn would alone afford the facts for settling its formula. After the unpromising trials with bromine and iodine I have attempted to arrive at better results by boiling nataloïn with dilute sulphuric acid. This was done in a tube previously filled with common illuminating gas and then sealed in order to exclude the influence of air. The liquid nevertheless turned dark purplish; it was slowly evaporated after it had been saturated with carbonate of barium. A new body then made its appearance, consisting of colourless very thin feather-like crystals. But this body was always formed in a very trifling quantity only, so that I have not been able as yet to isolate it;* it dissolves in methylic alcohol and all the above liquids as well as the accompanying products of decomposition. A similarly unpromising result was obtained by gently warming zinc, dilute acetic acid and nataloïn. The latter then becomes greenish and is at last dissolved; if the zinc is separated by means of sulphuretted hydrogen, the liquid, on evaporating, turns likewise purplish, tastes no longer bitter, but gives only traces of a crystallized body resembling that formed by the action of dilute sulphuric acid.

By a mixture of nitric and sulphuric acids, both concentrated, no available compound of nataloïn is formed.

In alkaline liquids nataloïn is also soluble, but very quickly darkened; by dry distillation, yellow or brown oily acid liquids are produced, which are devoid of any peculiar aromatic odour.

The whole of the foregoing facts do not yet allow us to form an idea of the constitution and the true chemical nature of nataloïn, but they are sufficient to prove that it is a new body, certainly differing from the aloïn hitherto known, although in percentage composition there is no considerable discrepancy between the two principles,—probably none at all.

I have also received from London some aloes which I am informed had been imported from Zanzibar, and was offered for sale in 1867. This drug is of a pallid reddish-brown hue, and so highly crystalline that it might fairly be termed *crude aloïn*. Mr. Hanbury is of opinion that it is not distinct from the so-called *socotrine aloes*, but that it is formed by the spontaneous drying up of the more crystalline portion which settles down when fluid socotrine aloes is allowed to repose. He assures me further that he has noticed that the solid Zanzibar aloes which is imported, though but rarely, in skins, is partly glossy and transparent, and partly highly crystalline.

Whatever may be the true facts, the crystals of the Zanzibar drug are comparatively large prisms such as I have never observed in, nor obtained from Natal aloes, and the pale, dull liver colour of the latter is extremely dissimilar to the reddish hue of the Zanzibar sort. The crystals of Zanzibar aloes cannot be so easily isolated as nataloïn, because their solubility approaches much nearer that of the amorphous part of the drug. They may, however, be obtained by water or dilute alcohol in the manner pointed out in the several papers of Stenhouse, Smith, and Groves, for the preparation of aloïn. Mr. Histed, who has been kind enough to send me some good quantities, obtained his crystals by moistening the powdered crude drug with alcohol sp. gr. ·960, and strongly pressing the pasty mass in several thicknesses of calico;—then dissolving the yellowish crystalline residue in warm, weak alcohol, collecting the crystals which form by cooling and repose, and purifying them by recrystallization.

Aloïn from Zanzibar aloes is usually less bright in tint than nataloïn, the crystals being smaller and not well developed. The crystallographic character of Zanzibar aloïn is different from that of nataloïn, the former consisting of what I cannot as yet better designate than as *tufted needle-shaped prisms*. The best solvent for them appears to be methylic alcohol, from which I find that very good crystals, 2 to 3 millimetres long

* Perhaps one of the products of decomposition of aloes, alluded to by Rochleder in 1861 and 1863?

and nearly 1 millimetre broad can be obtained. Zanzibar aloïn is much more soluble than nataloïn. At ordinary temperatures 30 parts of spirit of wine, 9 parts of acetic ether, 380 parts of (sulphuric) ether, and 90 parts of water are capable of dissolving respectively one part of the said aloïn, while in methylic alcohol it is most abundantly soluble. These numbers sufficiently illustrate the dissimilarity of the bodies under examination. But there are yet other points of difference. In concentrated sulphuric acid, Zanzibar aloïn is soluble; but on addition of an oxidizing substance as nitric acid, no alteration of the yellow colour of the liquid takes place, as when nataloïn is similarly treated.

The taste of the two substances is a little different,—Zanzibar aloïn imparting at first a slight sense of sweetness (quickly followed by pure bitter) not perceptible in nataloïn.

Again, the Zanzibar aloïn contains water, which it gives off over concentrated sulphuric acid. The air-dried substance lost in several days from 11·7 to 12·4 per cent., and on exposure to the open air again absorbed slowly about the same quantity of water. This air-dried aloïn kept at 212° F. for ten days lost 14·5 per cent.; the loss of weight amounted to only 13·2 per cent. if it was heated at 320° (160° C.) for some hours only. I have repeatedly performed these experiments relating to the amount of water which is contained in the air-dried substance, because it is again very different from Stenhouse's statements concerning his aloïn. His aloïn $C_{34}H_{19}O_{15}$ (old way of writing) loses only 2·69 per cent. of water, when dried at 212° F. for some hours, and not 11 to 12 per cent. like mine obtained from Zanzibar aloes.

Yet, as to the elementary composition, that of my *anhydrous* substance agrees with that of Stenhouse's *crystallized* hydrate as nearly as possible. He gives the following numbers * for aloïn dried *in vacuo*:—

		Calculated.	I. analysis.	II.
34 C	2550·0	59·47	59·39	59·24
19 H	237·5	5·54	5·97	5·79
15 O	1500·0	34·99		
		100·00		

On the other hand, 0·2108 gramme of the aloïn prepared by Mr. Histed from Zanzibar aloes, which I dried three days over sulphuric acid until its weight was no longer diminished, yielded me 0·4576 carbonic acid and 0·1128 water, that is to say it contains carbon 59·20, and hydrogen 5·94.

Thus, adopting the *new atomic weights*, we have—

		Calculated.	Stenhouse. (Average.)	Flückiger.
34 C	408	59·47	59·3	59·2
38 H	38	5·54	5·9	5·9
15 O	240	34·99	—	—

But Stenhouse admits his aloïn to contain 1 mol. of water and consequently assigns to it the formula $C_{34}H_{36}O_{14} + H_2O$, whereas my analysis relates to a body, which, as it has been dried over sulphuric acid, I regard as anhydrous. By the heat of the steam bath it further loses about 3 per cent., but I think this loss rather depends upon decomposition, the substance assuming a somewhat darker coloration. These suggestions are confirmed by the above statements, which showed that air-dry aloïn from Zanzibar aloes loses over sulphuric acid 11 to 12 per cent. of its weight. If we suppose, as we are well entitled, this loss to consist of water, we may then attribute to my substance, air-dried, the formula $C_{34}H_{38}O_{15} + 5\ H_2O$; it would require 11·59 per cent. of water, a number closely enough agreeing with my actual observations, as has been shown.

I have been unable to prepare from the Zanzibar aloïn the crystallized bromine compound (bromaloïn) which appears so easily obtainable from the aloïn of Barbados aloes.

The reaction of nitric acid on the two aloïns is also distinctive,—with the latter a deep red colour being produced, which is not manifested by the former, or by nataloïn.

All these facts lead to the conviction that the aloïn extracted from Zanzibar aloes is not only distinct from nataloïn, but also from the aloïn obtained by Messrs. Smith from Barbados aloes. I have nevertheless not yet thought it convenient to give another name to aloïn furnished by the Zanzibar drug, still further investigation being desirable.

One fact, at all events, results from the above researches, namely, that there occurs in aloes more than one crystalline principle.

Parliamentary and Law Proceedings.

The Alleged Attempt to Poison by a Lady.

At Brighton, on Thursday, August 24, Christiana Edmunds was brought up on remand, charged with having attempted to administer poison to Mrs. Emily Beard, with intent to commit murder.

The first witness was Emily Agate, a cook in the service of Dr. Beard, who said she recollected a cake being brought down into the kitchen. She ate a piece of it, and in about an hour and a half she felt giddy and sick, with a hot sensation in her throat, and afterwards had diarrhœa.

Adam May, a little boy, eleven years of age, who was identified as having been seen with the prisoner, said, about five or six weeks previously a lady asked him to go an errand for her. She went with him till they were opposite to Mr. Garrett's, when she sent him in with a note. Mr. Garrett gave him a book, which he brought to the lady, who was waiting for it.

Mrs. Cole said that about a week previous to the inquest on the boy named Barker, the prisoner called at her shop and made a small purchase. After she had left witness found a bag with Mr. Maynard's name printed on it, lying in a pail near the counter. On opening the bag she found some chocolate creams, and a smaller bag with three lemon bulls'-eyes. She and her daughter ate the bulls'-eyes. Her daughter also put a piece of one of the creams in her mouth, but spat it out again. The creams were put aside, and next day were given to a little boy named Walker, the son of a customer. On a previous occasion,—in March, she believed,—the prisoner had made a purchase in her shop, and after her leaving, witness had found a bag of chocolate creams on the counter. These were eaten by her daughter and another person. She saw the prisoner at the inquest on the boy Barker, and recognizing her, asked her whether she had dropped any chocolate creams in the shop. The prisoner denied having dropped any.

Mrs. Walker said she remembered her son bringing home some chocolate-creams about the middle of June. She ate a piece of one about the size of half a walnut. About ten minutes afterwards she felt a sensation in her head as if her eyes were coming out; something seemed to strain them. She got a glass of water, but was unable to put it to her mouth, on account of her hands and arms shaking so. Her legs and arms were convulsed. With great effort she got upstairs, but was quite unable to reach the door to call for help. She did not notice any unusual taste to the cream at first, but when she turned the brown part over in her mouth, it had a bitter taste that remained in her mouth a whole day. She recovered without medical attendance.

William Moon, eleven years and a half old, said that on July 19th, the prisoner asked him to go to Mr. Garrett's, in the Queen's Road, with a note. He gave the note to Mr. Garrett, who gave him in return what appeared to be a letter; this he took to the prisoner, who was waiting for him at the bottom of Upper North Street.

Mr. Isaac Garrett, chemist, at 10, Queen's Road, said he had known the prisoner as a customer for about four years. She only called in occasionally till the beginning of this year, when her visits began to be more frequent. She purchased generally toilet articles, such as soap, etc., and also quinine and iron mixtures. She usually came between nine and ten in the morning, and frequently made observations about the weather being cold for riding, having to return by the next train, etc. On March the 28th, after buying some toilet articles, she asked if he could supply her with a small quantity of strychnia to destroy some cats with, as her garden was very much infested with them, and she and her husband wished to get rid of them in this way. Witness objected to supply her. He said it was such a potent poison that he did not care to supply anything of the kind. Prisoner said she would give it straight into her husband's hands, and as they had no children no harm could possibly come of it, for she would be very careful. Witness then told her he could not supply her unless it was in the presence of a witness, who must be well known to both of them. She said the only person in the neighbourhood that she was acquainted with was a Mrs. Stone, with whom she was in the habit of dealing. Mrs. Stone lived three doors from him, where she then kept a milliner's shop, and he requested the prisoner to bring her. He then served her with the strychnia, and she signed his poison register book (produced), "Mrs. Wood, Hillside, Kingston," and Mrs. Stone signed it as a witness. The quantity of strychnia sold to her was ten grains. The prisoner called in at the shop several times between March 28th and April 15th to make purchases. She was taking quinine at the time. Witness had flowers in his shop, and she frequently made observations about her garden. She asked him if he was fond of asparagus, and brought two bundles on two separate occasions. She came into his shop on April 15th. She said the cats in her garden were quite as numerous and destructive as ever, and that the strychnia had apparently had no effect on them. She then asked him to supply her with more. He told her that he was very particular and anxious about it, and she repeated what she had said previously as to her having no children, and that no harm could therefore arise from it. He told her that he should require a witness to sign the register as before. She fetched Mrs. Stone as a witness again, and he sold her another ten grains of strychnia. He filled up the entry in the book (produced), and the prisoner signed it. He saw her on several occasions between that time and May 11th. She said that she was still taking the quinine and iron which she bought of him, and also that she and her husband were about to leave Kingston and go to Devonshire to reside. She also said that she should call before she left to have a supply of the quinine and iron mixture, as it had done her so much good. On May 11th she came to fetch the supply of quinine and iron which he had prepared. She then asked him to supply her with a little more strychnia to kill a dog, which she stated to be so very old and diseased her husband could not take it with him, and did not wish to leave it behind. He then cautioned her strongly again against the use of strychnia; but, ultimately, supplied her with it without a witness, but she signed the book as before in his presence, omitting, however, the address. The quantity was the same as on the previous occasions, ten grains. He did not see her after this till Friday last, when she was on trial, and that was the first time he heard her proper name.

Mrs. Stone said that she carried on the business of a milliner. In March last a lady, whom she believed to be the prisoner, but was unable to swear to, as she was so closely veiled, made a purchase at her shop. About five minutes after she returned and asked her, as a great favour, if she would oblige her by going into Mr. Garrett's to sign her name as a witness, as she wanted some poison to stuff birds, her husband and herself being naturalists. Witness hesitated for some time, and asked her for her name and address. She said her name was Mrs. Wood, and that she resided at Kingston. She said not the slightest harm would result from her being a witness. At last witness consented to go with her. Witness said to Mr. Garrett, "What have I to do?" He said, "You have to sign your name here." She said, "I hope I am not going to sign my death warrant." Mr. Garrett smiled, and replied, "It is only a form which is obliged to be filled up since the new Act, which must be signed by some householder." No entry was made in the book either by Mr. Garrett or the lady while witness was there. She did not pay much attention to the book to see what was entered. She was nearsighted. Witness recollected the lady coming to her again on the 15th April. She bought another veil. She then said, "I have to thank you for doing me a favour last time, will you be kind enough to do it again, and sign Mr. Garrett's book?" Witness went with her to Mr. Garrett's and signed as before.

Mr. Garrett was then recalled, and shown a small pink box, something in the form of a collar box, but smaller. He said he received it by post on the 10th or 11th Aug. The box contained two fresh peaches. There was a piece of tissue-paper between the peaches, and there was also a piece of note-paper, containing half a sovereign. On the note-paper was written, "The last of my debt, and the first of my fruit from my garden." The person whom he knew at this time as Mrs. Wood was not indebted to him.

Mr. William Curtis deposed that he had received by post a box containing crystallized fruit. Some persons were ill through eating the fruit.

Detective Gibbs said he had received a box (produced) from the prisoner's mother, at 16, Gloucester Place, where the prisoner and her mother lodge. He had conversation with the prisoner herself about the box the same afternoon. On going into the room he found her lying on the couch. She said, "Here you are again, Mr. Gibbs, and I am nearly poisoned. You have heard that I have had a box sent me with some fruit in it. It came on Thursday evening, about half-past seven, by post. It is evident it is some one in the town, for it bears only the Brighton post-mark, and it is evident it is no one connected with me, or they would have known my address and how to have spelled my name properly, for it is written 'm-o-n' instead of 'm-u-n,' and the address is put 17, Gloucester Place, instead of 16." Witness asked her what the box had contained, and she said, "Some strawberries, two apricots, and a pair of new gloves." He asked her what she had done with them, and she said, "Mrs. Edmunds ate the strawberries and I had one apricot, and it was all right. I bit the other, and it was dreadfully bitter. I spat it all out and have been ill ever since." She asked him different questions about the other boxes that had been received, Mrs. Beard's and others. She said, "Is it true that some other boxes have been received, and that Mrs. Beard has had one?" Witness said, "Yes, also Mrs. Boys, Grand Parade, and Mr. Curtis, of the *Gazette*, North Street." She replied, "Oh, how very strange. I feel certain you'll never find it out." The prisoner appeared to be suffering from illness and looked very pale.

Adelaide Ann Friend, housemaid to Mrs. Beerling, of Albert Terrace, Margate, deposed that the prisoner slept at her mistress's house two nights. Witness saw two boxes like those produced, and opened them. One contained two peaches, and the other crystallized fruit. A third box, like that which prisoner asserted to have been sent to her, stood by the others on the table. It was empty.

Charlotte Pettit, servant to Mrs. Freeman, said the prisoner had lodged with her mistress since March.

She remembered her going to Margate. On Friday, the 4th August, witness was in the lobby looking into the garden, when the prisoner brought some powders on a waiter in packets partly undone. There were no labels, but it was evident that there had been some, which had either been torn off accidentally in opening them or purposely. She said, "Take these away." One of the powders witness thought was powdered myrrh, and therefore kept; the other she threw on the fire. The powder which she thought was myrrh she kept on the dresser, and subsequently gave to Detective Gibbs, She recollected a lady of the name of Taylor lodging in Mrs. Freeman's house. She had a favourite dog that died on May 27. The dog was ill rather more than half an hour. Prior to the dog being taken ill Miss Edmunds was with it. It was in good health previously. Miss Edmunds was with the dog about an hour before it died, and half an hour before it was taken ill. The dog before it died stretched its legs out, shuffled about, and twisted round and round, as if with a sort of choking sensation.

The prisoner was then remanded for a week.

Poisoning by Arsenic.

On Wednesday, August 23, the coroner for West Somerset held an inquest at Cutcombe on the body of Maria Norman, aged twenty-one years, who was accidentally poisoned on the Thursday previous, The following evidence was adduced:—

James Norman said he was a farmer residing at Higher-house Farm, in the parish of Cutcombe. The deceased was his daughter. On Thursday morning she went on the hill with him, and returned between nine and ten o'clock a.m., appearing very well. On his return to the house about eleven o'clock, she appeared very unwell, and his wife said she had given her some senna tea. He went on the farm again and about dinner-time returned. Deceased was then gone to bed. Whilst at dinner, Mr. Bond, a seller of oils for cattle and medicine for people, came in, and his wife told him that deceased was very ill, and at her request he saw her. He came downstairs and said there was not much the matter with her, and there was no necessity of sending for a doctor; she had wind on the stomach through taking some brimstone which we told him she had had in the morning. He asked witness to let him see some of the same sort. Witness went to the back kitchen where it was kept and brought him some of it. He looked at it and said he thought it was nothing but pure brimstone. In the course of an hour and a half he saw her again. He said "You needn't trouble about her; if you like to send for a doctor you can, but there is no need for it." Next morning, seeing that she was very ill, witness sent for a doctor. She died about 10 a.m., before he arrived. Witness continued, I produce the barrel containing the brimstone as it was left in the back house. I obtained it from Mr. Harwood, of the Crown, Exford. I sent for 10 lbs. of arsenic, 40 lbs. of brimstone, and 60 lbs. of black soap. I gave him a verbal order and received the two packets produced, each being marked "POISON" in large letters, as it is now. One packet, which I thought was arsenic, I put away; and the other was opened for use, viz. to dip the sheep in a solution of it to kill the vermin. I considered that the packet which I opened was pure brimstone, and having arsenic in the house, I made a composition of arsenic, this supposed brimstone, and black soap. It was opened in the back house, and any one could go there and take it. We have had pure brimstone from Mr. Quick for years past, and my family have been in the habit of taking it.

Ann Norman, a sister of the deceased, deposed that on Thursday morning the deceased said there was something breaking out on her arm, and her mother said, "Why don't you take a little brimstone? there is some upstairs." Deceased said there was some nearer, down in the back kitchen; and she took a cup and teaspoon, and went towards the back kitchen. Three or four hours afterwards she was taken ill.

Mary Norman, another sister, said she saw her return from the back house with something in a cup, which was the colour of brimstone, about a teaspoonful. She said, "Poll, do you think this is good?" Witness replied, "Yes." She went into the dairy, witness thought for some milk to take with it, which was their usual way of taking brimstone. The packet and barrel produced were in the back house, and witness considered it contained simple brimstone.

Dr. Norman said he had made a *post-mortem* examination of the body, the appearance of which he described. He took away a portion of the powder from the packet in the barrel produced, and a portion of vomited matter which he was told the deceased had vomited just before she died. He sent these under seal to Mr. Stoddart, of Bristol, with a request that he would analyse them. Mr. Stoddart reported that he found the yellow powder to be a mechanical mixture of white arsenic and sulphur. The liquid in the bottle was milky-looking, and under the microscope was full of small globules of oil. It also contained arsenic in solution in considerable quantity. Witness was of opinion from this report and the *post-mortem* appearance, that the deceased died from inflammation of the stomach from taking arsenic. He should think there would be twenty grains in a teaspoonful of the compound.

The coroner then carefully summed up the evidence to the jury, who returned a verdict "That the deceased took a quantity of a compound containing arsenic in mistake for simple brimstone, by means of which she became poisoned by the same arsenic, which produced inflammation of the stomach, of which she died."

The coroner remarked that the packet being marked "Poison," the father ought to have been more particular in placing it in a secure place, and that such a virulent substance, having all the appearance of brimstone, ought to be coloured by those who had the sending it out. He was not sure whether some Act of Parliament did not compel persons to do so.

Obituary.

WILLIAM FLOCKHART.

We regret to announce the sudden death of this gentleman, at his residence, Annacroich, Kinross. Mr. Flockhart had been in his usual health until recently, but on Wednesday was seized with a severe attack of stomach cramp. Eminent medical aid was summoned from Edinburgh, but he never rallied, and died at ten o'clock on Thursday morning. Few names are better known in pharmacy than the eminent firm of Duncan, Flockhart and Co., of which the deceased was one of the original partners. Professor Christison, in his 'Dispensatory' (a volume now "scarce") acknowledges the valuable aid and information, as well as many selected specimens of pharmaceutical products, for which he was indebted to this firm; and the late Professor Sir James Y. Simpson owed much of his early success in the anæsthetic use of chloroform to the care and fidelity with which his experimental samples of that chemical were prepared by them. Connected with a profession requiring the closest personal attention for the faithful and successful discharge of onerous and responsible duties, Mr. Flockhart was little known in political circles, or in connection with municipal matters; but his private benevolences have been large and unobtrusive—indeed, the pecuniary and professional aid given to many deserving assistants on commencing business can never be forgotten by beneficiaries, or known to others. Mr. Flockhart was about sixty-three years of age, and has left a widow and two children to mourn his loss.—*Scotsman.*

Poison Regulations.

Sir,—From reading Dr. Greenhow's report upon the examinations of the Pharmaceutical Society, published in your last Journal, I am led to presume that that gentleman will entertain views entirely opposed to those expressed by Messrs. Simon, Sandford and the other promoters of the "Compulsory Poison Regulations." On remarking upon the difference which exists between the grade of chemist and druggist and pharmaceutical chemist, he says, "I am of opinion further, that inasmuch as the increase of practical pharmaceutical skill is what will most conduce to the service of the public," etc. etc. Now I think he has there hit the right nail upon the head, and expresses the views of by far the larger portion of our profession.

If a man by observation, study and practice, so educates himself that he is able to pass the requisite examinations, it seems only natural that, of his own free will and in his own interests, he will use his utmost endeavours to prevent mistakes, and will have his business regulated and carried on in the best style suited to his own particular case. We must take into account the great difference there exists between each and every business; regulations suitable for a business in London would not at all do for the majority of country businesses.

I believe, as it has been frequently stated, that whatever regulations may be enforced, they will in no way diminish the number of accidents, that number being so small in comparison with the amount of business transacted. I would suggest that the agitators for compulsory poison regulations should accept the concluding passage of Dr. Greenhow's report as a sufficient guarantee, and that they should turn their attention more to the education of forthcoming chemists, to fit them for examination. I think, then, they will do far more service to their country.

B. H. Cowgill.

Burnley, August 26th, 1871.

The Pharmacy Bill.

Sir,—Like a good many others, I am thoroughly tired of the poison controversy going on in your Journal, and would not have added a single word if it had not been for the poisoning case now under investigation in Brighton.

I have no desire to reason or argue with opponents who do not wish to be convinced; I feel certain that sooner or later the Privy Council will relieve us all by passing a law compelling every chemist to adopt precautions similar to those already carried out in every well-conducted and reputed establishment. I place also very little importance in the voluminous lists of our opponents, judging from the way in which returns were obtained in this town, for I am led to believe that should the poison regulation question be once more seriously discussed, the numbers would disappear like mist, leaving a few leaders in unenviable distinctness. Anyhow, the names of those who at a moment's notice signed the petition in favour of legislative interference, when compared with those who were against it, leave not a particle of doubt in the mind of any sensible man, of what really should be done. Names like Bell, Corbyn, Dinneford, Godfrey and Cook, Hanbury, Savage, etc. etc., carry more weight than all the chemists of the back streets of London and other towns taken together.

That the principles upon which these great houses manage their business differ from those of the great number of smaller houses is nothing new or surprising; it is just this occasional difference which has brought them their present world-wide reputation, a difference which usually consisted in being a few steps in advance of others. The public, moreover, is a very good and competent judge in those matters, and requires no mouthpiece to tell them where to go for the best and most carefully-prepared medicine, and to whom to apply for poisons. The leading houses refuse to sell poisons to anybody except those who are personally well known to them; their poison register book is a great blank, while small indifferent places of business are so powerfully influenced by the fear of losing a customer as to have their sense of responsibility most wonderfully blunted. To preach to these about the uselessness of legal interference and to praise their own discretion, only leads to mischief. It would have been more salutary and wise to insist on the necessity of adopting the strictest rules and precautions in the selling and keeping of poisons, and to render such sales as rare and difficult an occurrence as possible. Every objection on that head should be met with the reply, "The greater the opposition, the clearer the necessity for lawful compulsion."

Brighton, August 28th, 1871. J. Schweitzer.

The Council of the North British Branch of the Pharmaceutical Society.

Sir,—I beg most respectfully to decline taking the advice Mr. Mackay tenders me through the columns of last Saturday's Journal. There was nothing in my last letter to convey the idea that I did not know the constitution of this Council; while the fact of my being a young member of the Society is no reason whatever that I should be ignorant of what he states. I fancy his ideas of the intelligence of his Scottish brethren in trade, myself in particular, must be of the lowest order, if he considers that we would really become members of a society, and months afterwards require to wander over the back volumes of its Journal for its history. But I shall not comment further on the manner in which Mr. Mackay has treated my communication, as any person comparing the two letters will see, at a glance, that his is not a direct reply to mine, but a mild attempt to snub what he possibly considers an aspirant to fame. I will, however, endeavour to supply a few omissions I consider he has made in his statement, in the hope that he may make use of them the next time he expounds the constitution and history of the North British Branch. They are as follows:—

Taking into consideration the facts that this very Council's report of our transactions, together with the proceedings of our annual meetings, were sent to the May numbers of the Journal and published, and that the Scotch have proverbially good memories, we did not think it at all necessary to advertise this meeting in the Journal previous to the meeting being held in April, nor for many years have we seen fit to send out circulars inviting all the members of the Society in Scotland to attend these meetings; this would have put the Society to considerable expense, not to say of extra trouble to its secretary, while we found it was quite unnecessary.

We have always held our annual meetings in the evening, as we know our friends do not object to come to Edinburgh and spend a night in the 'Douglas' for the purpose of attending them, and asserting their rights with regard to the election of the Council of the North British Branch.

I need not say we made all comers welcome who were members of the Pharmaceutical Society, and we, of course, always managed to get a few gentlemen from some of the small burghs in the immediate neighbourhood of Edinburgh to attend these meetings, whose names in the report in the Journal, with the towns they belonged to attached, looked as if we had an array of talent from all parts of the country; for we know it is a natural failing of our friends south of the border that they have but little geographical knowledge of Scotland. You will thus see that though the pharmaceutists of Glasgow, and perhaps other towns, were asleep, it was not our fault; indeed, some of us even went the length of making an occasional tour round, to endeavour to awaken them out of their state of stupor; but this had not much effect, till at length, rather than disturb our brethren in their slumbers, and not wishing to be called illiberal, we took upon ourselves the responsibility of electing to the Council Board a gentleman or two to represent Dundee and Glasgow. We did not ask these gentlemen whether they could attend our Council meetings or not; we, however, sometimes sent a notice to them, requesting them to come to the meetings of Council, but finding them always asleep, we neglected doing so when anything of importance was to be discussed, making the hurry our excuse, for we had a secret instinct telling us that if we aroused the fellows properly, it was just possible they might take Museum, Library, money grant, honour and all from us; for though I have said the clause in the Act of 1852 gives Edinburgh an examining body, the clause also says that Glasgow, or other place or places in Scotland, may be selected at the discretion of the Council in London.

I have heard it whispered that the hundred and odd pounds we get in the year from the parent Society to defray the expense of the Society in Scotland, (which is independent of the expenses connected with the examination,) has hitherto precluded some of the other provincial societies in Scotland from asking a grant from the same source; and we think it is just possible that it might be a barrier to them getting a grant were they to ask it, for the large towns in England are jealous of Scotland getting too many advantages. We are sorry, however, that we have no inclination to give up any part of the money we get, as we require it all to ourselves; and if your friends had not been asleep when the good things were being handed out at first, matters might have been different; they must now, however, accept the consequences.

Considering all this, and seeing you are such a young member of society, Mr. Fairlie, take my advice, lay your pen aside, and go to sleep with the rest of your brethren; at all events, do not disturb the "Council of the North British Branch of the Pharmaceutical Society of Great Britain."

I may just add, that I do not take up this matter from any jealousy on my part or that of any of my friends here,—the very reverse. We yet cannot see any reason to remove the examining body from Edinburgh to Glasgow, or elsewhere, as we believe thoroughly that the present Board do their duties conscientiously enough; and having hitherto received nothing but kindness at the hands of our Edinburgh brethren, we only wish that good feelings will continue to be reciprocated between us. My object, however, is to point out that Edinburgh is not North Britain, and that if the North British Branch of the Pharmaceutical Society is to be looked upon as such, it must be conducted in a more open and liberal manner. I therefore hope that the next, and all future annual meetings, of this Society shall be held at an hour in the day to suit both country and town members; and further, that sufficient notice be given, both in the Journal and otherwise, prior to the meeting taking place; and above all, that the election of the Council be conducted in a formal manner by voting papers, etc. If this is not done, our Edinburgh friends may expect that ere long "the heather will be on fire;" when they will, perhaps, regret their exclusion of other large towns in this matter.

JAMES M. FAIRLIE.

St. George's Cross, Glasgow, August 8th, 1871.

Sir,—I venture to offer a few remarks upon Mr. Mackay's reply to Mr. Fairlie on this subject, being desirous that the question of this Council's relation to the members of the Pharmaceutical Society in Scotland should be properly understood by old, new and prospective members. For though Mr. Mackay has favoured us with a *résumé* of the constitution and history of this Council, he has left the matter as to the mode in which it is elected and its powers pretty much where they were; and this I think was the point indicated in Mr. Fairlie's wish to have the question discussed. At least many of my pharmaceutical friends in different parts of the country, as well as myself, have frequently wondered what authority they had for using the title "North British Branch," seeing it was, if not wholly, at least to a very large extent, an Edinburgh institution. It is all very well for Mr. Mackay to say now, when he is brought to book, that an annual meeting was held every year, and that it has always been their regret that they could not induce more of their country friends to come forward. But how could they expect country friends to come to these meetings if they did not intimate to them beforehand that such a meeting was to take place? It is all but likely that they would ask some of their particular friends of the larger towns to come; but speaking for the country towns, I know there are gentlemen who have been five, ten and even fifteen years connected with the Society who have not received so much as one invitation to attend their annual meetings further than their annual report referred to by Mr. Mackay, which was, of course, always published a month or six weeks after the meeting had taken place, and this surely could not be looked upon as any announcement for a future meeting. As regards the Glasgow chemists being pharmaceutically asleep hitherto, I think it does not speak greatly in favour of Mr. Mackay and his Edinburgh friends that it has been so. It is only an hour or so by rail between the two places, and surely it was their duty, as leaders of the Society in Scotland, to endeavour at least to awaken them out of their languid state they had fallen into as regards things pharmaceutically. But there is too much conservatism in our Edinburgh friends to do so; in fact, to my mind, at least, they resemble in almost all things the London pharmacists. We all know how near we were having the poison regulations enforced upon us by a sidewind of the London chemists at last annual meeting, and in this case of the amended Bill and the Edinburgh Council, though Mr. Mackay says there was no intent to deceive, the fact is still there, that they call themselves the Council of the North British Branch of the Pharmaceutical Society, which, if it means anything, must mean the representative body of the pharmaceutists of Scotland, which they know it is not, though it may contain some of the oldest and best known members of the profession. With regard to the statement of Mr. Mackay, that Edinburgh is allowed by a clause in the Act of 1852 to have an examining body, I may just remind him that it is at the submission of the Scotch pharmacists that they are allowed such, and not by the Act alone; for, if the Scottish members were to demand that the examining body should sit either in Glasgow or elsewhere, the London Council would hardly refuse to give their authority for such, so that this is another instance of the overbearing manner of the Edinburgh chemists over their other brethren in trade. And I grant it is a question, now that Glasgow has awakened out of her slumber, whether she should not be considering the propriety of having this body removed somewhat nearer the west, that our young men may be saved part of the expense now incurred in passing the examinations, and also get some of the good things which it is rumoured are only to be had through such close proximity to headquarters.

M.P.S. IN THE COUNTRY.

DRUGGISTS' PRICES.

Sir,—Having been much interested in the late discussion in your pages relative to druggists' charges, believing that in such discussion or exposure of what is termed the "cutting" system, as applied to dispensing charges, will be found one potent remedy for the evil, I regret nevertheless to add a further illustration to the long catalogue already chronicled by you. I had handed to me this evening a recipe, of which the following is a copy, with the request to "see that it was properly made up," some doubts being expressed as to its being faithfully dispensed elsewhere, on a previous occasion:—

Powd. Turkey Rhubarb
Comp. Ext. Colocynth
Ext. Chamomile
Castile Soap, of each two scruples.
Mix and divide into pills.

After finishing and dividing the above into forty-two pills, I was asked what the charge would be, and on naming what I regarded as the *very* moderate sum of one shilling, you may imagine my astonishment and annoyance at being told that I was "*sixpence above* Mr. ——."

On my expressing surprise that any druggist could undertake to dispense the recipe for such a sum, I was favoured with the names of three registered chemists in the vicinity, all of whom had charged for it the paltry sum of sixpence! Had such a statement been made by a stranger I might have disputed it, but coming as it did from what I know to be a trustworthy source, I saw no reason to doubt its correctness.

The absurdity of such charges will be still further apparent if we consider that, had the sale been that of a quack medicine, containing probably *less than half* the quantity of pills above mentioned, the stereotyped 1*s.* 1½*d.* or 2*s.* 9*d.* would have been obtained without a murmur, and with no further trouble to the seller than that of handing it across the counter.

"In all labour there is profit," if we are to accept Scriptural testimony on the subject, though too many of our brethren appear to set at nought the dictum of the wise man, so far as dispensing is concerned, if we may judge from the foregoing, in addition to the many instances to the same effect, already recorded in your correspondence.

We read and hear much, at the present time, of the evils of "over-regulation prices," in relation to military matters; would that we could obtain even "regulation prices" in matters pharmaceutical!

N. O. P.

Mexborough, Yorkshire, July 24th, 1871.

Stoddart, Mr. J. Mackay, Messrs. Arnold and Sons, Mr. Lucas, Mr. J. David, M. M. B., B. R., J. S. H., "Ferrum," "Harry," "Dispenser," "Theta."

SEEDS IN DRUG-PARCELS:

EXPERIMENTS ON THEIR VITALITY AND CONSEQUENT USEFULNESS.

BY G. BROWNEN.

In the examination of drug-parcels for adulterations or worthless articles, an interesting and profitable field of inquiry is often overlooked. When bits of stone, earth, twine, decayed or worm-eaten drugs, etc., are removed, our duty appears done, and the parcel is either used or passed into stock.

Among the leaves, gums, barks and roots, still remain numberless seeds of various sizes, shapes and Orders—a wonder and a study in themselves, which may afford means for demonstrating many a page of Bentley's 'Botany'; or if a little trouble, care, or patience (whichever term is best) be taken with them, may be induced to germinate, and reward the effort with plants on which the botanical pharmacist will certainly look with curiosity and interest.

Last year, for the first time, this plan was adopted by me, and specimens were collected, classified as nearly as possible, and their vitality tested in the spring.

From the following parcels of drugs, a great variety of seeds and fruits were obtained, thus:—

	Varieties.		Varieties.
From Chimaphila,	2	From Senna,	7
Uva Ursi,	2	Serpentary,	4
Sumbul,	3	Buchu,	3
Anchusa,	2	Cusparia,	5
Senega,	3	Canella,	3
Ammoniacum,	4	Coca	1
Chirata,	2	Myrrh,	3
Cascarilla,	11	Matico,	3
Acacia,	10	Kino,	1
Tragacanth,	3	Calumba,	6
Cusso,	2	Cinchona,	8

Of seeds or fruits, recognized either by their structural characteristics or the plants produced from them, were the following:—

Linseed, coriander, ricinus, croton, coffee, fenugreek, areca, pomegranate, papyrus, jatropha, prunus, senna, buchu, dates, and myrobalans.

Their vitality was then tested; 103 specimens were placed on a piece of muslin, and floated on water for a few hours; many of them were thus softened or swollen in size, they were then slightly covered with mould, and forced with artificial heat. On examining the beds when the heat had declined, 27 were found to have germinated, and many were overlooked or lost.

Such a success warranted further experiments, and I planted a selection, but owing to the advanced period of the season, several sprung up and died away; others survived till the severity of last winter destroyed them, and I had only 3 or 4 left alive, and a few withered stalks of annuals for a first year's produce.

Determined to succeed, if possible, I commenced again this year, only unfortunately 1871 did not resemble 1870. Midsummer and Christmas seemed to have exchanged places, and this year's success as yet is very small.

As many of the seeds were known as medicinal articles, I determined to extend my list, and experiment on as many as I could find; of course, their numbers were greatly increased, and possibly many failed from want of proper attention, etc.; if, however, an herbarium or a structural museum be the object sought, their number may be diminished, or successful plants need not be replanted; and failures sought out and understood serve as guides to success. To study, collect, or preserve a plant when its structural peculiarities are fully developed, or in operation, will render comprehensible such terms as æstivation, etc., quicker and more correctly than months of mere book study; the definitions of *Scrophulariaceæ*, *Labiatæ*, *Atropaceæ*, and *Solanaceæ*, will lose their uncertainties, and be as easily separated in practice as in theory.

Of the official seeds and fruits, most may be induced to grow even in thickly populated towns—on housetops or window-sills—anywhere that a pot or a box of mould may stand and be watered or sunned into life. I have seen many of them growing on a flat roof in one of the most thickly populated parts of London; and one must be excessively hard worked who cannot find a few minutes, between dawn and dusk, to attend or watch the growth of such plants.

Where a greenhouse or other facilities exist—with all due respect to common garden plants—pharmaceutical plants comprise some of the most elegant; thus, stramonium, ricinus, or colocynth have elegant foliage; squills, crocus, colchicum and lobelia are good flowering plants; ginger, turmeric and cardamoms will compare favourably with the grasses; the beauty of orange, pomegranate, or capsicum fruits is not to be despised; and roses and poppies are quite beyond all question.

Many an important pharmacopœial plant, while flowering, would not be misplaced in a pharmacist's shop, it would neither indicate inattention to business, nor a want of pharmaceutical knowledge.

Official, typical, or plants having peculiar structural features need not be squeezed or pressed flat as a passover cake, in the abnormal style of the herbarium, whose decurrent, sessile and amplexicaul leaves appear most puzzlingly alike, especially to a young beginner. These plants may be dried, root and all if you like, in a mixture of 98 sand and 2 of stearine or any high-melting fat; in such a mixture, leaves, stalks and stems may be dried in their natural positions.

These dried plants, preserved from insect ravages by some insecticide, or varnished, may be planted in a pot of dry sand, and thus show their foliation, dehiscence, etc. They are as durable as skeleton plants. If they are not so beautiful as well-pressed specimens, they are more natural. Any one looking at the favourite microscopic slide, "the tongue of the blow-fly," squeezed as it is into elegance, could form little conception of that member as seen *in situ;* so, in botany, a flat specimen of *Hyoscyamus*, *Dulcamara*, or *Digitalis* resembles but faintly the mode of growth or form of those plants.

Having such an idea of an illustrative or natural botanical collection, those seed and seedlings would be carefully attended, and, when their peculiarities are developed, our necessaries would be ready to dry them.

Returning to medicinal seeds again, notice the success already obtained in scarcely two seasons.

Fifty-nine different specimens of seeds, exclusive of those already mentioned as obtained from drug-parcels, were planted, and the following have sprung up since the spring of 1870:—Dill, caraway, colchicum, colocynth, fig, henbane, mustard, white poppy, stramonium, tobacco, chamomile and cardamom.

Four other plants were obtained by the following methods:—First, liquorice, by planting a piece of the fresh root; this produced a plant three feet high last year, although it was set in a pot.

Secondly, some green ginger rhizomes were set, and twenty-three stems, ranging from nine to thirty-two inches in height, were obtained—beautiful Scitamineous specimens; these rhizomes are still alive, and shoots six inches high have sprung up out-of-doors, uncovered, notwithstanding the variations of weather and temperature.

Thirdly, two bulbs of squills were obtained and planted, and, after more than a year's inaction, one bulb has thrown down six or seven rootlets, and is beginning an upward movement; the other bulb may soon follow the example given, for it has assumed a very red and swollen condition.

Lastly, by the kindness of a friend I have a rhizome of turmeric, and it has unfolded its leaves, and is in a flourishing condition in an open window.

Ricinus is in full flower in the open garden, and several palms (*Phœnix*) are growing outside the window.

Of uncertain varieties, three shoots have appeared above ground this year in the "Ex. Acaciæ," one in "Ex. Calumbæ," two in "Ex. Cascarillæ," and five in "Ex. Sennæ" compartments. A pot containing *Jatropha* seeds was knocked over and smashed in a nightly scrimmage of cats; two of the seeds had sprouted about an inch. Whether they will recover from the shock, time will prove. A date palm, sixteen inches high, began to show signs of decay; its root had gone through the pot, and was doubled up underneath, raising the pot from the saucer in which it stood.

This is a brief description of what has been accomplished, without hothouse or stove. I have been afraid to plant all my seeds on account of the uncertainty of the weather; consequently, I have specimens or collections of many reserved.

I do not profess to have discovered a new field of research. Lobel and Don attempted to discover the source of galbanum from seed they found adhering to the gum (Royle, page 472). The tenacity of life in squill-bulbs has been noticed in a previous PHARMACEUTICAL JOURNAL; and the longevity of certain seed may be seen by referring to PHARM. JOURN. Vol. XVII. 1st series, pp. 224 and 328.

If these remarks should lead to a more extended investigation of these too often neglected botanical treasures, we may possibly add to the scanty knowledge we possess of many medical plants, and certainly obtain a cheap herbarium, or a collection of every stage of plant-growths.

SUGAR DETERMINATION IN URINE.

BY PROFESSOR SEEGEN.

The author read a paper before the Medical Society of Vienna, on "Sugar Determination," in which he first detailed the importance to the physician of proving the presence of sugar in urine, and then dwelt upon the contradictory results of existing methods of analysis, especially in regard to the presence of sugar in many physiological conditions, as, for instance, during pregnancy and during the period of suckling, after inhalation of chloroform and ether, etc. The author was thereby induced to test all existing methods, and he arrived at the following results:—

We have no reagent to prove minute traces of sugar dissolved in urine beyond doubt and to the exclusion of other analogous substances.

All statements as to the presence of minute quantities of sugar in many physiological and pathological conditions must be received with caution.

Normal urine does not contain it in sufficiently large quantities to allow of its determination.

Normal urine contains minute quantities of reducing substances, but whether they consist of sugar, partially or wholly, cannot be determined with our known tests.

Albuminous Urine and a New Reagent.—The precipitate obtained by heating urine with nitric acid is carefully washed to remove the last traces of urine, and it is then redissolved in a little potash, a few drops of Fehling's copper solution added; a fine violet coloration is instantly produced, especially with a strong solution; the reaction is very characteristic, and readily shows one per cent. of albumen.—*Zeitschrift d. allg. oest. Apoth. Verein.*

HISTORICAL OUTLINES OF PHARMACY IN SPAIN.

BY DR. T. B. ULLERSPERGER, OF MUNICH.

(*Concluded from page* 183.)

The first Pharmacopœia known in Europe was written in 1497 by Pedro Benedicto Mateo, a pharmacist in Barcelona, whose works were edited in 1521 by his son, under the title of 'De Loculentissimo viro ac Sacro Apothecario Artis divini Professoris T. B. Matei.

In 1522 F. de Sepulverda published a Pharmacopœia under the name of 'Manipulus Medicinarum, impresa en la Ciudad de Vitoria;' a second edition of which appeared at Valladolid in 1550. Before writing his books he traversed the whole of Spain, to attend the lectures of the most celebrated teachers, and then went to the University of Salamanca to profit by the instructions of the professors of pharmacy.

Between 1521 and 1527 Bernardino de Laredo, a Franciscan monk, compiled his 'Modus Faciendi cum Ordine Medicandi.' In 1535 appeared at Barcelona the 'Concordia Pharmacopolarum Barchinonensium,' augmented and revised in 1587 by Pedro Benedicto Sola, in conjunction with the pharmacist Bernardo Domonech, and with Juan Benedicto Pau.

Pedro Jaime Esteve, of Valencia, in 1552 translated from the Greek his 'Nicandri Colophonii Poetæ et Medici Theriaci.' In the following year appeared the 'Concordia Aromaticorum Cæsar-Augustæ, in quâ continentur Epithome omnium Antidotorum usualium ad unguem nuper correcta ex Fœdere eorundem Pharmacopolarum. Tractacus sinonimorum, in quo voces, quæ in hoc Volumine continentur obscuræ, exponuntur, etc., Autoribus non vulgaribus desumptus; Cæsar-Augustæ ap. Steph. de Nogera, anno 1553, quo Michael Sagaun et Bernardinus Azarues Collegio Pharmacopolarum præpositi erant."

This is one of the first Pharmacopœias embellished with poetry; the only known copy of this remarkable book was at that time already in the possession of the Pharmaceutical College at Barcelona. This rare work is divided into three parts, the last of which is entitled 'Tractatus in quo pretia Omnium

Medicamentorum Simplicium et Compositorum traduntur, quod vulgus "Tarifum" apellitat,' which is undoubtedly the oldest printed tariff or price-list.

A copy of the work dated 1651 is also in existence; at the end of it is written "expliciti sunt tractatus tres in quibus tradere epitomè o'ium antidotorum usualium et tractatus synonymorum promisimus. Cæsar-Auguste per Stephan. G. de Nogera ad laudem individuæ Trinitatis et Virginis intactæ; qui nostras agūt causas pridie Kalendas Junii anno 1553." Before the preface is written "Divisio libri," into the three parts, and then "Carmina in laudem operis et tractatus de po'deribus et mensuris, quibus pharmacopei et medici utuntur." The continuation consists of verses on simple remedies and their selection, and then four lines of original poetry; the manuscript of the copy is on ninety-two sheets demy.

In 1552 Luiz Callado published his 'Index Farmacopœarum, quæ in usu sunt apud Nostras Pharmacopœas,' and in 1586 Simon Todar's 'Nova Methodus Compositorum Medicaminum' appeared, as also in 1587 his 'Hispalensium Pharmacopoliorum Recognitionem,' at which Francisco Sanchez de Orepesa assisted him.

The first twenty years of the seventeenth century were of great importance to Spanish pharmacy, inasmuch as Philip II. issued several laws concerning the examination of pharmacists (Pragmatica, November, 1817).

These laws made it prohibitory for physicians and chirurgeons to dispense; medicines had to be made up under heavy penalties by none but pharmacists by examination. In 1650, under Philip IV., the exercise of pharmacy was declared a profession and scientific art, quite on a par with medicine. Pharmacists of that time were not permitted to carry on any business which might interfere with or distract their attention from the proper exercise of their profession. The first tariff legally enforced throughout the whole kingdom was published about this time. A record of all laws referring to pharmacy, especially those treating of the examination and of the education of pharmacists will be found in Gonzalo Samano's 'Medicina Española.'

A more complete Pharmacopœia was published in 1601 by the Colegio Farmacéutico in Valencia, under the title 'Officinam Medicamentorum et Methodum recte eadem componendi; cum variis Scholiis et Aliis quam plurimis, ipsi operi necessariis, ex sententia Pharmacopolarum Valentiorum. Valencia por Juan Crisostomo Garriz, 1601, in 2°.' A second edition was published in 1698 by the same College, and also in the same year at Zaragoza with additions, the last under the name of 'Officina Medicamentorum et Methodus recte eadem componendi, cum variis Scholiis et Aliis quam Plurimis ipsi operi necessariis; et sententia Valentinorum Pharmacopolarum, auctore eorundem Collegio, præfectis Collegii Antonio Joanne Insa et Joanne Baptista Catarroja, hinc et examinatoribus Gulielmo Salvador Borras et Francisco Joanne Molina, scriba artis Rocho Linyerola. Segundo tomo: La Farmacéutica de Francisco Velez de Arciniega. Tercer Tomo: exámen de Boticarios, por el P. Fr. Estaban de Villa. Van añadidos los Tarifas del Reino de Aragon y Ciudad de Zaragoza; y se dedica à los Sñrs. Illmos. Diputados del Reino de Aragon, Zaragoza, por Gaspar Tomás Martinez, 1693, in 2°.'

The professors of pharmacy and chemistry in conjunction with the Colegio of pharmacists at Madrid, published in 1739 the 'Pharmacopeia Matritensis Regii ac Supremi Hispaniarum Proto-Medicatus, auctoritate, jussu atque auspiciis nunc primum elaborata.' It is dedicated to Don José Cervi, whose likeness is on the frontispiece. A new edition was published in 1762.

For many years Spain had ten universities where medical pharmacy had been taught—Barcelona, Granada, Madrid, Oviedo, Salamanca, Santiago, Sevilla, Valencia, Valladolid and Zaragoza. In 1859 there were faculties of special pharmacy at Barcelona, Granada, Madrid and Santiago with 5 professors and 544 students, 390 of whom were at Madrid.

There are also twelve places, mostly universities, institutes, observatories, etc., where meteorological observations are regularly taken, viz. Alicante, Barcelona, Bilbao, Granada, Madrid, Oviedo, Salamanca, Santiago, Sevilla, Valencia, Monte de Villaviciosa de Odoro (with special school for engineers) and Zaragoza.

It was stated before that Spain was remarkably rich in mineral springs, and we need not be surprised to find the 'Anuario Estadístico' of 1860 to register 98 baths and springs. The best book on this subject is the 'Tratado Completo de las Fuentes Minerales de España,' by Pedro Maria Rubio, Madrid, 1853.

Spain undoubtedly possesses the greatest number of benevolent institutions, and among the many a special one for pharmacists was early established. In the year 1780 the Council of Castille sanctioned the erection of an institution for the support of widows and orphans of physicians and pharmacists.

It is interesting to notice that the theriac formerly was publicly prepared, and a dispute on the preparation resulted in the compilation of a remarkable work, edited by the pharmacists of Madrid and entitled 'Explicacion de las Virtudes y Método de Usar la Triaca magna Matritense, elaborada por la Descripcion de Andromaco el viejo.' Con privilegio del Rey nr. 1 en presencia del real Protomédico por el Colegio de los Boticarios de Madrid en la Oficina de los Sñras. Desclazas reales,' sine loco et anno. This singular book contains the history of the nostrum, its action and its internal and external application.

The Spanish pharmacists have among them many writers of high repute. In 1866 there existed eight pharmaceutical journals, and in October of the same year the Colegio de Farmacéuticos de Madrid met, to agree upon the rules of the Congresso Farmacéutico Español.

The practice of homœopathy is sanctioned by royal decree: the system met there, as everywhere, with great opposition, especially the equality in the faculties, but it now seems to be pretty firmly established, —chiefly, perhaps, because it formerly was in favour at the Court.

In the middle of 1869 a Junta met at Madrid to organize an Asamblea Médico-Farmacéutica. The subjects to be discussed were pharmaceutical instruction, benevolent institutions, sanitary matters on sea and land, mineral springs, forensic medicines and pharmacy and medical responsibility. In the province of Cadiz alone over 100 members joined.

In August, 1869, the Colegio de Farmacéuticos celebrated their 132nd anniversary. After the Elegio Histórico the following subjects were discussed, viz. the restoration of pharmacy, the duty to protect it against contagion of trade, to guard it against quackery, to improve the position of pharmacy and its sister, medicine, and to secure the sacred rights of humanity.

We cannot fail to observe that in Spain more than in other countries pharmacy and medicine go hand in hand, both professions taking equal rank; and this will explain that pharmacology there is not so much allied with therapeutics as with pharmacy. In conjunction with therapeutics pharmacology is only met with in French books translated into Spanish, whereas the relationship to pharmacy appears in all recent original Spanish books. We will only quote two, viz., 'Manual de Analysis Química aplicada á las Ciencias Médicas,' por Don T. R. Gomez Pamo, Dr. Pharm., a Member del Colegio de Farmacéuticos de Madrid, 1870. It contains the direct application of medicine and pharmacy, chapters on mineral springs, Spanish and foreign, on fluids of the human body, on aliments and medicaments, then practical methods for analysing industrial products most in use, and a short Tractado de Toxicologia.

The second work we select is 'Química Orgánica General y Aplicada á la Farmacia, Medicina, Industria, Agricultura y Artes, por el Dr. Don G. de la Puerta, Professor of Pharmacy at the University of Madrid, 1870.

Although the profession may not be quite so advanced as in other countries, still there is an active tendency to progress. The prescribing and dispensing are simple and rational, and no trace is left of the complicated formulas of the Galeno-Arabic time, although they obtained until the sixteenth century.—*Buchner's Repert. d. Pharm.*

INQUIRIES RELATING TO PHARMACOLOGY AND ECONOMIC BOTANY.*

BY DANIEL HANBURY, F.R.S.,

AND PROFESSOR OLIVER, F.R.S.

From the *Admiralty Manual of Scientific Inquiry.*

Asia Minor, Armenia, and Persia.

Gum Tragacanth is produced in Asia Minor by several species of *Astragalus*, which it is desirable further to identify. Travellers and others who have the opportunity should preserve specimens of any species *seen* to yield the gum, as well as specimens of the gum itself; noting at the same time whether the latter was obtained from incision in the stem, or whether exuded spontaneously. Fine gum tragacanth is produced at Caissar (or Kaisarieh) and Yalavatz, in Asia Minor, at which places the practice of making longitudinal incisions in the stem of the shrub is adopted; the gum is also collected at Isbarta, Bourda, Angora, etc.

Gum tragacanth is frequently adulterated with another gum, which has been called *False Tragacanth, Hog Gum, Bassora Gum*, or *Gum Kutera*. At Smyrna it appears to be known as *Caraman Gum*. What is its origin? One of its properties is to swell up into an opaque mass upon being placed in water, in which, however, it does not dissolve.

Storax.—None of the storax found in commerce in modern times is derived from *Styrax officinale*, L.; yet it is certain that this tree is capable, under favourable circumstances, of yielding a highly fragrant resin which was once much valued. Authentic specimens of this resin, which is the original and legitimate *storax*, are much desired. It was formerly produced in the south of Asia Minor, where the tree is still found in abundance.

Salep.—Obtain specimens of the different plants which yield salep in Asia Minor and Persia, and especially of those that afford the best kinds.

Larch Agaric (*Polyporus officinalis*, Fries).—This fungus now comes from Northern Russia, where it grows on the stems of *Larix sibirica*, Ledeb. During the middle ages it was exported from Asia Minor; and in the Paris Exhibition specimens from this region, that is to say, from the Gulf of Adalia, were exhibited. What is the tree from which this Asiatic Agaric is obtained?

Assafœtida.—Although the ordinary assafœtida of commerce is doubtless the produce of *Narthax Assafœtida*, Falc., there are some varieties of the drug which, it is reasonable to conclude, are derived from other species. One of those sent from India to the Great Exhibition of 1851 was a brown pellucid gum-resin, containing pieces of the stalk of the plant, and differing considerably from ordinary assafœtida.

Sagapenum, a gum-resin resembling assafœtida, but not acquiring a pink colour upon exposure to the air, and of not so strong an alliaceous odour. As it is occasionally shipped from Bombay, it is presumed that it is produced in Persia. Though it has been used in medicine for ages, its botanical origin is not ascertained; from analogy, however, we may infer that it is the produce of some large plant of the Natural Order *Umbelliferæ*. Compared with assafœtida and galbanum, sagapenum is a rare and costly drug.

Galbanum.—The remarks we have made upon sagapenum apply, to a great extent, to the gum-resin known as *Galbanum*. Galbanum is, however, a far more abundant substance than sagapenum. It occurs in trade in two varieties, which are so distinct as to lead to the inference that they are yielded by distinct plants. Galbanum is said to be imported into Russia in large quantities by way of Astrachan, but that which reaches England comes principally from Bombay.

Opopanax, another fœtid gum-resin, the produce, according to most authorities, of *Opopanax Chironium*, Koch, a large umbelliferous plant, native of the south of Europe, and of Asia Minor. There is no modern account of the collection of this drug, nor is its place of production ascertained.

Africa—West Coast.

Copal.—Sierra Leone copal is produced by *Guibourtia copallifera*, Bennett, *Kobo* of the natives: of this tree, which is not well known, specimens, including the ripe pods, are requested; it grows at Goderich and in other localities near Sierra Leone.

Grains of Paradise.—Although *Amomum Melegueta*, Roscoe, the plant which yields this drug, is now well known, there are some interesting species nearly allied, with which botanists are very imperfectly acquainted. It is, therefore, desirable to procure specimens of such plants from various parts of the West Coast of Africa. These specimens should comprise the flowers and fruits, as well as the foliage. As the flowers are very delicate, it is necessary to preserve them in spirit of wine. Some specimens of the fruits should also be preserved in the same manner. As the species often grow intermixed, and as flowers and fruits are produced at different seasons, special care is requisite to avoid confusion.

African Turmeric is said to be the rhizome of *Canna speciosa*, Rosc., but further investigation is desirable. Living roots might easily be procured at Sierra Leone, and sent to England for cultivation.

African Mammee (*Ochrocarpus africanus*, Oliv.), native of Sierra Leone and Prince's Island. Specimens of the tree, and (in alcohol) of the fruits, which are as large as an orange, are requested.

---

* Information relating to any of the subjects here referred to may be addressed to Mr. Hanbury, Clapham Common, near London, or to Professor Oliver, Royal Gardens, Kew.

BITTER KOLA of Fernando Po.—The common *Bitter Kola* (*Cola Nuts*), largely used by the natives of West Tropical Africa, is known to be the produce of a wide-spread tree, *Cola acuminata*, Br., but the origin of the *Bitter Kola* of Fernando Po is still uncertain. There can be no doubt that it is the seed of a Guttifer (*Garcinia* or *Xanthochymus*), so it must be sought on a tree with strictly opposite leaves; the seeds probably contained in a pulpy fruit.

BALSAM OF ST. THOMAS is the name of a tree growing in the island of St. Thomas, in the Gulf of Guinea. Specimens in flower and fruit, also of the resin, if it afford such, with information as to the mode of procuring it, would be acceptable. It is probably a species of *Sorindeia*.

BITTER WOOD. A species of *Quassia* (*Q. africana*, Baill.) is found in the Gaboon and Camaroons rivers. Specimens of the wood are required to show whether it may serve as a substitute for the Tropical American species (*Q. amara*).

What is the Kpokpoka tree of West Tropical Africa, from the fibre of which the "dodo" cloth is prepared? Specimens in flower are wanted.

Specimens in flower or fruit of any shrubs or trees of Upper Guinea, affording elastic gums, *india-rubber* or *gutta-percha*, with accompanying gum and mode of its collection, are particularly requested.

AFRICA—EAST COAST, INCLUDING THE RED SEA, ARABIA AND MADAGASCAR.

MYRRH.—This celebrated drug is collected in great quantities by the Somali tribes on the African coast, near the southern extremity of the Red Sea, whence it is brought to Aden for shipment to Bombay. A variety of myrrh, which is probably yielded by another species, is also produced (according to Vaughan) in a district lying forty miles to the east of Aden, to which place it is brought for sale. A third variety, distinguished by the Arabs as *Bissa Bôl*, is also collected by the Somali tribes, and sent by way of Aden to India. It is a point of much interest to determine with accuracy the plants which afford these several sorts of myrrh, and for this end it is earnestly requested that those who have any opportunity for investigating the subject will not neglect to do so.

OLIBANUM.—The Olibanum found in European commerce is produced partly on the African coast, near Cape Gardafui, and partly on the southern coast of Arabia, whence it is shipped to Bombay. There is still some doubt about the various species of *Boswellia* which yield the drug, and additional specimens, including flowers and mature fruits, are desired.

KORARIMA CARDAMOM is the name under which the late Dr. Pereira has described an Abyssinian cardamom, having the shape and size of a small fig, which is exported from Mussowah, a port at the southern end of the Red Sea. This drug, which has long been known in medicine, is perforated at the smaller end, and, when strung upon a cord, is commonly used by the Arabs and Abyssinians as beads for their *mesbehas* or rosaries. It is said to be brought to the market of Baso, in Southern Abyssinia, from Tumhé, a country situated in about 9° N. lat. and 35° E. long. The plant, for which the name *Amomum Korarima* has been proposed, is entirely unknown.

DRAGON'S BLOOD, of the Island of Socotra—By what plant is it afforded?

CATHA EDULIS, called in Arabic *Kât*. A large supply of the dried leaves of this shrub, say one hundred pounds, should be procured for chemical examination. The plant grows in Southern Arabia and in Abyssinia.

KAMALA.—A peculiar sort of Kamala, evidently not derived from *Rottlera tinctoria*, Roxb., has been imported from Aden. Nothing is known of its place of growth or of the plant by which it is afforded. (PHARM. JOURN. IX. (1868), p. 179.)

KOUSSO.—Fresh seeds of the Kousso tree, *Brayera anthelmintica*, Kunth, should be procured for cultivation.

GUM ARABIC.—*Acacia Verek*, Guill. et Perrott., a tree growing all over the northern part of Central Africa from Senegambia to Abyssinia, is said to produce the best sort of gum arabic. Fragments of the stem, with the gum exuding, from Western as well as from Eastern Africa, are requested, in order to ascertain the identity or diversity of the gum produced by one and the same plant in different localities.

CALUMBA ROOT.—Whether this drug is furnished wholly by *Jateorhiza Columba*, Miers, or in part by *J. Miersii*, Oliv., both of them plants of Mozambique (but the latter found also in Madagascar), is not known. Travellers visiting the localities where the drug is collected should obtain good specimens of the plant, as well as living roots, which are fleshy and easily transported without earth.

TANGHIN of Madagascar (*Tanghinia venenifera*, Poir.).—A specimen is requested of the poisonous milky juice. A portion should be partially dried with a gentle heat; another portion should be mixed with spirit of wine and sent in a fluid state.

CAOUTCHOUC, or INDIARUBBER.—In Madagascar, as well as in Mozambique, there are several trees said to yield this substance. Good specimens and definite information should be collected.

INDIA, SIAM, AND THE INDIAN ARCHIPELAGO.

CATECHU.—Observe the processes by which the various kinds of *Catechu*, *Cutch*, *Terra Japonica*, and *Gambir* are obtained; and, if from trees, whether from others besides *Acacia Catechu*, *Areca Catechu* and *Uncaria Gambir*. We wish to identify the trees with the respective extracts.

What is the source of Pegu Cutch, especially?

BENZOIN, OR GUM BENJAMIN.—It would be interesting to obtain good specimens of the tree which affords this drug in Siam in order to compare them with *Styrax Benzoin*, Dryand., which produces the Benzoin of Sumatra.

CAMPHOR OF BLUMEA GRANDIS, D.C.—Some pounds of it are desirable, in order that its nature may be investigated. (See 'Pharmacopœia of India,' p. 123.)

MISHMI BITTER, or MISHMI TITA.—The small yellow rhizome of *Coptis Teta*, Wall., a drug known in medicine since a remote period, is produced in the Mishmi mountains to the east of Assam, and probably also somewhere on the confines of China further north. The plant which yields it is very little known, and complete specimens are desirable. It is possible that some second species may furnish a portion of the drug.

ACONITE ROOT has been imported in considerable quantities from India. In what district is it collected, and from what species of *Aconitum*?

AROMATIC BARKS, known as CULITLAWANG, MASOY, and SINTOC, derived from trees of the Order *Laurineæ*, are objects of considerable trade in the Indian Archipelago. The traveller should embrace the opportunity, when it occurs, of seeing the bark collected, and of obtaining authentic specimens of it, and of the tree yielding it. Masoy bark is produced on the west coast of New Guinea.

(*To be continued.*)

THE HONEY TRADE.

BY P. L. SIMMONDS.

(*Concluded from page* 184.)

The ceremonies of the Greek church requiring a large consumption of wax candles, greatly favours this branch of rural economy in Russia, and preserves it from the decline to which it is exposed in other countries, from the increasing use of stearine, oil, gas, and other fluids.

for illuminating purposes. The peasants produce wax so cheaply that, notwithstanding the consumption of this article has greatly diminished abroad, it still continues to form an important item of the commerce of the country; but the exportation of honey has considerably increased in consequence of the extended use of potato-syrup, which has also injured the honey trade in the interior. The rearing of bees is now almost exclusively dependent on the manufacture of candles for religious ceremonies, and on the consumption of honey during Lent, it being then used instead of sugar by the strict observers of the fasts.

The Government encourages this branch of rural industry, as affording to the peasant an extra source of income, and has adopted various measures for the accomplishment of this end. With the view of diffusing the requisite knowledge among the people of the public domains, bee-hives, and a course of practical instruction upon the subject of bee culture, have been established at several of the Crown farms, and pupils are sent every year, at the expense of the government, to the special school in Tschernigow, founded for the purpose in 1828. After having finished their studies, the pupils quitting this establishment may become teachers in the schools dependent on the Ministry of Domains, or carry on the business of teaching on their own account. They enjoy a temporary exemption from military service, and such of them as wish to establish hives for themselves obtain loans for the purpose from the Department of Rural Economy. By way of further encouragement, the Ministry of Domains has granted permission to the peasants to establish hives in the Crown forests, under the precautions necessary to prevent the occurrence of conflagrations.

The total production of wax in Russia was estimated, ten or twelve years ago, at 5,412,000 pounds per annum; and, as the usual calculation is three pounds of honey to one of wax, this supposes a production of 16,236,000 pounds of honey, the whole being valued at £450,000. The Cossacks keep large stocks of bees; the number of apiaries is upwards of 1500, containing more than 31,000 hives, and producing annually about 300,000 pounds weight of honey and wax.

A large quantity of honey is obtained in various provinces of Italy, such as Valtelina, Lombardy and Volterra, in Tuscany, in Sicily and in Sardinia, where it has an exquisite flavour, for which it enjoys a high reputation. This production amounts to about 3,750,000 pounds. The bitter honey is a peculiar kind, which is found in Sardinia. It has no unpleasant property. It appears to derive its character from the heaths, which in certain localities seem to support exclusively the bees.

The sweet and aromatic nature of the plants of Greece gives to the honey produced there peculiar qualities, which have been celebrated by her poets. The honey of Hymettus has always been the most distinguished, according to the testimony of Theophrastus and Dioscorides, who say "The best honey is that of Attica, and of that the most excellent is from Hymettus, and the honey of Xanysto, which is called rose honey; the latter kind is produced only at Xanysto, and it takes its odour from the wild rose, which furnishes the food of the bees." But this sort of honey is not produced every year, as it is influenced by the growth of the wild rose, and is hence called rhodomele. Honey is gathered at two different seasons, viz. May and June, and August; the first produced is the best. Some years ago the annual quantity exported from the ports of the Piræus, Gythion, Calamas, and Chalcidia, exceeded 300,000 pounds weight. In the five years ending 1864 the average quantity of honey produced in the island of Porto Rico was 4,000,000 gallons a year.

The honey of Spain is abundant and of excellent quality. The variety of aromatic plants of the family of *Labiaceæ* (thyme) furnishes abundant food to the bees. The honey called azalar, because it is furnished by the bees who take the pollen and the sweet sap of the nectars of the orange blossoms, is renowned in Seville and Cordova. The price of the honey of the latter locality is, however, more than double that of the former. The honey of Huelva, obtained in the village of Hinoiosa, is the principal product of the district.

About ten years ago an extensive traffic was carried on in the transit of quantities of hives of bees from the Atlantic to the Pacific States of America. Many hundreds of hives were brought down by the Hudson River railroad to New York, and shipped there by steamer and rail to Panama, and then sent on to California, where they were sold to great pecuniary advantage within a few days. For some reason, apparently not very well understood, the bees do not thrive in California without artificial aid, although the country seems to afford abundant means of sustenance. One lot of hives which cost 14 dollars each were sold for 75 dollars each hive. Another venture resulted still more successfully. The bees were transported in the hives they had filled. One side of each hive had a wire gauze, which admitted air freely; and, on board the cars and steamers, they were stored so as to secure good ventilation. This trade was carried on for several years. Some information concerning the honey trade in the United States has recently been printed in this Journal.*

It has been estimated that the pasture of Scotland could maintain as many bees as would, on an average, produce 80,000,000 quarts of honey, and 1,000,000 pounds of wax. Were this quantity tripled for England and Ireland, the produce of the kingdom would be 240,000,000 quarts of honey, and 3,000,000 pounds of wax annually. The income that would thus arise from honey, at the very moderate price of 2*s*. 6*d*. per quart, would amount to £3,000,000 sterling, and the wax, at 1*s*. 6*d*. per pound, would produce £225,000 sterling.

Endeavours should always be made to have beds of the earliest spring flowers cared for by bees near the hives. Winter aconite (*Eranthis hyemalis*) is their earliest friend, and, growing only about four inches high, does well below and about the hives. Then comes their dearly loved crocus, single *Hepatica*, coltsfoot (*Tussilago Petasites*), the invaluable palm-willow, and then turnip and cabbage flowers. Buckwheat is advised by some bee authors; but I have not found they cared much for it. Mignonette should be grown largely for them, but their chief food in summer consists of white clover and common heather or "ling" (*Calluna vulgaris*); and in most places in Scotland one or both these flowers are so plentiful till the middle of September, that garden flowers, except in early spring, are of little importance. Those who will calculate the time lost by a bee flying many times a day, sometimes miles, to a heather moor and back again to its hive with his drop of honey, and will multiply that time by the crowd of workers sent out daily, will easily understand the immense importance of having their hives shifted to a heather moor in August, if at all possible—the great bulk of honey made in Scotland being derived from heather. This is so well understood in some parts, that I have seen several hundred hives sent in August to shepherds' houses in a moor, nearly all of which had come from the low country, many from twenty miles' distance. I have known such hives going to the moor nine pounds weight, and returning, five weeks afterwards, weighing sixty pounds; and unless the season is very wet, all do well when planted among the heather bloom. In fact, one bee thus situated does as much work as a dozen who have to fly many miles for their drop of honey. In Belgium I have seen spring-carts fitted nicely with shelves for hives, and crowded with them on their way to the heather moors of the Ardennes.—*Journal of Applied Science.*

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 9, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

CHEMISTS AND THE USE OF STILLS.

THERE seems yet to be considerable misapprehension as to the use of stills by chemists, and among other illustrations of the fact we have received the following letter on the subject:—

"Your correspondent 'Aqua Destillata' seems ignorant of the fact that for the use of a one-gallon still no licence or permit is necessary. He can use anything under two gallons without the interference of the Excise. If he wishes to use a larger one, he ought to pay the same licence as myself and others, or the Excise Commissioners would be acting unfairly towards us."

This is wrong. A chemist cannot use a still of less content than two gallons without a licence or special indulgence from the Board of Inland Revenue, any more than he can use one of larger capacity. It is true that immediately after the Act 9 & 10 Vic. c. 90 was passed, the Inland Revenue authorities allowed a *retort* of less content than two gallons to be used without licence, although the Act in question specifies that "any still or retort" is to be paid for. This indulgence was evidently granted for the reason that *retorts* are constantly used by chemists in their general business, and also that *retorts* cannot economically be employed for purifying or concentrating alcohol. However, since this permission to use *retorts* was given twenty-five years ago, and since the Board of Inland Revenue has power to withhold the indulgence at any time, it would perhaps be wise for those desirous of using, in their business, *retorts*—especially of large capacity—to ask the Board's permission before doing so.

The clause giving the Board of Inland Revenue the power to grant exemption from the payment of this duty is as follows:—

"Provided always that the Commissioners of Excise may permit the keeping and using of any still or stills for experiments in chemistry, under such regulations as they think fit; provided also, that the Commissioners of Excise may permit the keeping and using of any still or stills by persons carrying on trade or otherwise, for the manufacture of any articles other than spirits or spirit mixtures, upon every person who has a still giving notice thereof to the nearest officer of excise, and conforming to such regulations as the Commissioners of Excise think fit to direct before beginning to use any still as last aforesaid."

It is worthy of remark in regard to this matter, that in this clause reference is only made to stills, and although the Act specifically states that the "sum of ten shillings shall be yearly paid by every person keeping or using any still or retort, so long as any still or retort is kept or used as aforesaid," retorts are not mentioned at all.

THE SALE OF BENZINE COLLAS, ETC.

WE congratulate our readers that the Act for the safe keeping of petroleum and other substances of a like nature, passed at the end of the late session of Parliament, provides for the sale of benzine collas and similar articles without a petroleum licence. This matter has been the source of much annoyance, and has given great trouble to have it put on a satisfactory footing. According to section 7, the provisions of the Act respecting the regulations as to storage of petroleum shall not apply to petroleum kept either for private use or for sale, provided the following conditions are complied with:—

"(1.) That it is kept in separate glass, earthenware, or metal vessels, each of which contains not more than a pint, and is securely stopped.

"(2.) That the aggregate amount kept, supposing the whole contents of the vessels to be in bulk, does not exceed three gallons."

This question is therefore at length definitely settled, and druggists need not be under any further apprehension of annoyance on account of the sale of benzine collas or similar preparations.

THE EVENING MEETINGS.

THE first evening meeting of the session, to be held on Wednesday, October 4th, will, as usual, be devoted to the presentation of the prizes awarded to the successful students during the past session. The address to the students will be delivered by Mr. JOHN MACKAY, of Edinburgh. The Council, mindful of the additional interest given in past years to these special occasions by the presence of the ladies, have again extended their invitation to them.

As will be seen by reference to the official notices, the Council will be glad to receive for exhibition during that evening and the following day any articles of novelty or otherwise specially interesting to pharmacists.

THE BENEVOLENT FUND.

As there are but two candidates for the forthcoming election of annuitants on the Benevolent Fund, there will be no competition this year. We are requested to mention this in order to explain the non-issue of the usual voting-papers.

CHINESE AND INDIAN OPIUM.

The report from her Majesty's Consul at Shanghae, just published, states that the importation of Indian opium into China has been seriously affected by the competition it has met with from the native drug. Although the consumption of opium in China increases, year by year, the import of the foreign drug during the past four years has decreased, or, at the most, has remained stationary. A considerable quantity of the native drug from the provinces of Szechuen, Kweichow, and Yunan, now finds its way to Shanghae, where it is remuneratively disposed of at about half the price of the Malwa opium.

As an illustration of the extent to which the market is influenced by the rapidly increasing growth of the native poppy, it may be mentioned that in 1869, a report having become current that the Chinese Government had determined to put a stop to the growth of the poppy in its dominions, a brisk demand for Indian opium sprang up in consequence, which led to a rise of twenty per cent. in the price. When, however, it became evident that the Government had no real intention of carrying out such a project the price again receded.

Persian opium is reported to be coming into greater favour with the natives, especially in the northern provinces, where it is sold at a price considerably below that of Malwa.

ADULTERATION OF TEA.

Of all the articles of domestic use which in their turn are reported to undergo the process of adulteration, there is perhaps not one that bears a worse reputation than tea. Only a short time since a question was asked in the House of Commons in reference to a quantity of tea that had arrived in the docks, in which it was said that large quantities of iron-filings were present. Since then other adulterations have been reported as being practised by the Chinese, some of which are positively loathsome, and it is almost a relief to hear of one in which at least the repulsive features are absent.

Colonel Medhurst, her Majesty's Consul at Shanghae, reports an innovation in the art of adulteration, by means of willow leaves, which has recently sprung up, and threatens to grow into a trade that will seriously affect the quality of all classes of green tea sent from that port. He gives the following particulars concerning this fresh addition to our list of adulterants:—

"The preparation of the willow leaf for mixture with tea is openly practised in the villages of the Hong-keu side of the Soo-chow Creek, and it has become an industry which claims an important share of the attention of the villages of that and other localities. The banks of the numerous creeks are planted with willow-trees, the young leaves of which are collected in April and May, very much in the way that the tea leaf is gathered. The produce is then collected in heaps on the hard threshing-floors of the hamlets, and is allowed to undergo a mild fermentation in the sun. The leaves are then manipulated similarly to those of the ordinary tea-plant. They are sorted into kinds according to sizes, and afterwards roasted in common tea ovens. The appearance of the stuff after this treatment is not unlike that of the genuine article, and it is carried to Shanghae and there intermixed with pure tea, at a ratio of from 10 to 20 per cent.

"The cultivation and preparation of willow leaves were begun in Shanghae about ten years ago, and have increased year by year. The poorer classes near Shanghae have for a long period consumed this leaf as an infusion in place of tea, the latter being too expensive for them to purchase. As far as I can gather, its use is productive of no ill effect, but its flavour has not the slightest resemblance to any known tea. The cost of the article cannot exceed 2*d.* per pound, but when mixed with tea and so sold to foreigners, it must represent a very large profit to the producers.

"The interference of the authorities with regard to this spurious manufacture may shortly be necessary for the purpose, if not of its actual prohibition, which may not be possible, at all events of placing it under such control as that foreigners may be in a position to satisfy themselves as to the quantity produced, and the proportions used in mixing; so that the adulterated article may take its proper position in the tea market.

"From inquiries instituted through the superintendent of police, it transpires that there are at this moment about 400 piculs, say 53,000 lbs. of this willow leaf in the course of preparation at various drying-houses in the foreign settlements at Shanghae. The probable amount made up last season is estimated at not less than 3000 piculs or 400,000 lbs. I am not aware that any analysis of the properties of the willow leaf has as yet been made at Shanghae; but attention to the above facts will doubtless bring about an investigation of the kind, which is certainly demanded in the general interest, by the rapid expansion which is exhibiting itself in this feature of the tea trade."

MEETINGS OF GERMAN AND AUSTRIAN SOCIETIES.

The season of the various annual meetings of scientific societies on the Continent has commenced, as the following list, taken from the Zeitschrift der allg. oest. Apothekerverein, will show, viz.:—

Naturforscher Versammlung. The forty-fourth meeting of German natural philosophers and physicians at Rostock, Mecklenburg, from 18th to 24th inst.

Norddeutscher Apothekerverein, North German Pharmaceutical Union, Sept. 14 to 16, at Dresden.

Fifth general meeting of the Union Æsculapius of surgeons at Salzburg, took place Aug. 28 to 30.

Fifteenth meeting of Hungarian physicians and natural philosophers took place at Arad, from August 28th to September 2nd.

Tenth general meeting of the Austrian Pharmaceutical Society was held at Linz, Sept. 3 to 5.

Borax is said to occur in a crystallized state in a lake in Lake county, California. Until the winter of 1869 this lake was so shallow that the proprietors were able to obtain the borax cheaply by dredging. But the unusual quantity of rain that fell during that season increased the depth to eighteen feet, and the work was consequently suspended. This deposit of borax is supposed to be the largest in the world.

Transactions of the Pharmaceutical Society.

MEETING OF COUNCIL.

September 6th, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. EDWARDS, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Carr, Greenish, Groves, Hills, Savage, Stoddart, Sutton, and Williams.

The minutes of the last meeting were read and confirmed.

A letter from Mr. Deane was read in reference to the condition of the Museum, Library, and Specimens for the use of the Board of Examiners in Scotland.

The Council had an interview with Mr. Deane, and after some discussion, he having retired, it was

Moved by Mr. Greenish, seconded by Mr. Bottle:

Resolved—That Mr. Deane's letter be entered on the minutes, and that the following constitute a special Committee to report to the Council thereon:—

Committee: — The President, the Vice-President, Messrs. Betty, Frazer, Mackay, Sandford, Shaw, Sutton, and Williams.

The Report of the Finance Committee was presented, showing on the General Fund Account a balance in the Treasurer's hands of . . . . £1178. 8*s*. 8*d*.

And submitting for payment accounts amounting to . . . . £506. 16*s*. 11*d*.

On the Benevolent Fund Account subscriptions received during the month of August amounted to £14. 5*s*. 0*d*., making the balance in the Treasurer's hands of . . . . £245. 11*s*. 1*d*.

Resolved—That the Report be received and adopted, and payments made.

The Report of the Provincial Education Committee having been read, it was

Resolved that it be received.

The Report and recommendations of the Parliamentary Committee having been read, it was

Resolved—That they be received and adopted.

Resolved—That the Registrar be authorized, and is hereby instructed, to erase from the register the names of Thomas Letch, Edward Mickle, and William Laws.

Resolved—That John Jackson, of Wetherby, being duly registered as a Pharmaceutical Chemist, be elected a Member.

Resolved—That Richard Wood, of Macclesfield, a registered Chemist and Druggist, be elected a Member.

Resolved—That a Member having paid his arrears of subscription and a fine, be restored to his original status in the Society.

Resolved—That Henry J. Mornement, Associate of the Society before July, 1842, be elected a Member.

Moved by Mr. Williams, seconded by Mr. Betty,

That the following registered Chemists and Druggists be elected Members of the Society:—

Edward Gould .... Bromley.
John Middleton Wyborn ...... Bromley.

Mr. Groves called attention to the fact that these names had been submitted to the Council for election on a previous occasion, and stated that he still objected to their election on the ground that they were homœopathic chemists.

Mr. Williams said that Mr. Gould had spoken to him on the subject, and he certainly did not think they were acting fairly in not electing him. He was a man of standing, and he did not think they ought to draw a line and say they would not admit homœopathic chemists. Many of their members sold homœopathic medicines; and as Mr. Gould said, it was a most absurd thing that he should not be a member of the Society when some of his assistants were pharmaceutical chemists or chemists and druggists. Mr. Gould was properly registered under the Act, and claimed, as he thought rightly, to be elected a member of the Society. He brought it forward as a matter of principle.

Mr. Groves said that equally as a matter of principle he should vote against the motion.

Mr. Carr said he should do the same.

Mr. Edwards asked if there were any homœopathic chemists members of the Society.

The Secretary said he believed not.

Mr. Groves said the Society was one of Pharmaceutical Chemists; these men did not use the same Pharmacopœia, or the same drugs, nor had they anything to do with the Society. They might as well admit hydropathists.

Mr. Williams thought that under the Act of Parliament they were almost bound to elect any one properly placed on the register.

Mr. Atherton said they were not bound to admit anybody.

Mr. Edwards said the Act made a great distinction between matters for the public benefit and matters affecting their own internal arrangements as a Society. If a man passed a certain examination he was entitled to call himself a pharmaceutical chemist, and have all rights accruing to him as such, but making him a member of the Society was optional.

Mr. Bottle read clause 18 of the Act 1868,—"Every person who at the time of the passing of this Act is or has been in business on his own account as a chemist and druggist as aforesaid, and who shall be registered as a chemist and druggist, shall be *eligible* to be elected and continue a member of the Pharmaceutical Society according to the Bye-laws thereof."

Mr. Betty seconded the motion. He thought, under the words of the eighteenth clause, they were morally bound to elect any properly qualified person, because he recollected there was a long discussion on the meaning of the word "eligible" prior to the passing of the Act, and Mr. Sandford, the then President, stated that that word meant that there was a moral right in the persons referred to to be elected. Indeed, after communication with Mr. Flux upon the subject, he believed Mr. Sandford went so far as to say that with that word in the Act of Parliament there was a legal right, and he stated distinctly that he should have no objection to substitute the words "shall have a right." Again, they called themselves the Pharmaceutical Society, and according to etymology that included all who ministered to the public wants with regard to curing diseases. They had nothing to do with the manner in which those diseases were cured; homœopathic chemists dispensed the prescriptions of duly qualified medical practitioners, and he did not see how they could properly be excluded. If they cured diseases by a method which the old school did not think the best, that had nothing to do with the Pharmaceutical Society. He thought, therefore, they were morally bound to elect these gentlemen; and if there was no legal right, they should certainly act in a liberal rather than in a narrow spirit. At any rate he should like to hear some reason given for refusing to elect them.

Mr. Hills said his reason for voting against the election was that he did not think these gentlemen would do the Society any good, or that they would get any good from it. It might cause contention in the educational department, for they might wish to introduce lectures on homœopathic pharmacy.

Mr. Stoddart thought there would never be many of these men applying for membership, and they would not dream of instituting homœopathic lectures.

Mr. Hills said if he were a homœopathic chemist and a member, he should certainly bring it forward and try to introduce it.

Mr. Williams said that generally speaking homœopathic chemists were very well educated scientifically; indeed, rather above the average of chemists and druggists.

Mr. Sutton said his experience was quite the contrary.

Mr. Groves said if the Council acknowledged the status of these men, he did not see how they could draw the line and refuse to put on the register booksellers and others who had sold homœopathic medicines prior to the passing of the Pharmacy Act.

Mr. Williams said that was a distinct point. There was no question about the propriety of these men being on the register.

The motion was then put, and the following division took place:—

For—Messrs. Betty, Bottle, Savage, Stoddart and Williams (5).

Against—Messrs. Atherton, Carr, Greenish, Groves, Hills and Sutton (6).

The motion was therefore lost.

Messrs. Edwards and Haselden were present at the division, but did not vote.

Resolved—That the following having passed their respective examinations, be elected Associates in business:—

MINOR.

Hairsine, Herbert S. ....London.

MODIFIED.

Burkinshaw, William Thomas ..Belper.
Corrie, Andrew A. ....Bedford.

Resolved—That the following, having passed their respective examinations, be elected Associates of the Society:—

MINOR.

Webster, John ....Market Deeping.

MODIFIED.

Dickinson, William ....Manchester.
Hitchin, Robert ....Bradford.
Ray, William Herbert..........Barnet.
Sloman, Richard ....Norwood.
Stewart, William Henry........Paris.

Messrs. Benjamin Heald, of Sleaford, and J. S. Eyre, of Launceston, were appointed Local Secretaries to the Society.

Moved by Mr. Carr, seconded by Mr. Edwards:

Resolved—That as there are only two candidates for election on the Benevolent Fund in October next, no voting-papers be issued on this occasion.

A letter from Mr. Fletcher, one of the late candidates for the Jacob Bell Scholarships, was read, suggesting a revision of the rules relating to the competition for these Scholarships. Letter referred to the Library Museum and Laboratory Committee to consider and report thereon.

At the request of the Council, the President undertook to place a notice in the Journal intimating that novelties interesting to pharmaceutists would be exhibited at the ensuing evening meeting in October, and that persons desiring to exhibit should communicate with the Secretary.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Tuesday Afternoon, August 1.

Mr. H. Smith then read a paper by Messrs. T. and H. Smith, entitled "Notes on Aloes, with reference chiefly to the Cathartic qualities of Aloin."

The Chairman said that the two papers just read were very valuable, and he hoped they would elicit remarks from those specially acquainted with the use of aloes. As to the crystals, it seemed strange that from different kinds of aloes different crystals should be formed. He would like to know from Mr. Smith if there was any difference in the actual measurements. The shapes were different; although sometimes it appeared to the inexperienced eye a mass of crystals, there were two predominating angles. He believed it was possible to measure the crystals to a great nicety; and he would suggest to Messrs. Smith that they should kindly have the angles of the crystals measured, and tell whether there was much difference between the aloin from the different kinds of aloes. They did not use aloin in the West of England to the extent that it was used in Edinburgh and the North. He had no doubt of the activity of the aloin as a purgative, but he would like to know if observations had been made as to the relative use of it. In the West of England they were gradually going round to the idea that the Barbadoes aloes were the best to use. When he heard Mr. Smith say that there was more aloin to be obtained from the Barbadoes aloes than the others, he thought that was a further proof in support of Mr. Smith's assertion that it was a purgative. As to the application of aloin to horses, what Mr. Smith said as to a horse being sick and refusing its food, was the very thing they wished to avoid.

Mr. A. W. P. Smith said that aloin had no pretensions to anything superior to aloes other than activity. The great advantage of aloin over aloes was its reliable character, and that it was always to be trusted. The variable character of the crude drug was a great drawback.

Mr. T. Smith replied to some statements on the subject which appeared in the *Journal de Pharmacie*, and maintained that aloin was of great value.

Mr. Williams said it was very important they should know that different kinds of aloes yielded different kinds of crystals. He would like to know more about the different crystals produced, from the various aloes of commerce. He had no doubt that the Messrs. Smith could furnish the information. He himself had manufactured aloin, and he had found great difference in the yield; but the best yield was from the Barbadoes.

Professor Attfield made some confirmatory remarks as to the way in which the apparently contradictory statements as to the activity of aloes and aloin might possibly be found to harmonize. Bodies alike in appearance, coming from the same source and closely allied in chemical composition, were known to possess very different physiological properties. Thus Matthiessen and Wright's apomorphia had medicinal characters entirely different from those of morphia, but varied in chemical composition only to the extent of the elements of one molecule of water. Again, there were strong grounds for believing that codeia was a similar structure to morphia, except that one of the hydrogen corner-stones, so to speak, had been taken out and a methyl stone put in its place. Nay, similar modifications produced non-poisonous from poisonous compounds. Thus kakodylic acid, which contained as much arsenicum as was present in arsenic acid, had no effect on rabbits, and probably none on man. Hence he would not be surprised to find that different, or even similar, kinds of aloes contained different modifications of aloin varying in medicinal activity. This hypothesis might turn out to be valueless, but with such workers as Dr. Flückiger, the Messrs. Smith and Dr. Tilden, and the discussion of the matter by such gentlemen, there was no doubt that the truth must sooner or later be unveiled.

Mr. Hanbury said he did not think that Dr. Tilden professed that his remarks on the subject were derived from experience. He merely argued that aloin was little used, and therefore of little use.

Dr. Cook said that while aloes themselves were not easily alterable by chemical agents, aloin was susceptible of alteration, and he explained some experiments he had made.

Mr. C. H. Wood said he thought that the paper of Dr. Flückiger embodied what must be a growing conviction in the minds of many that the crystalline principle obtained from aloes varied considerably,—that one description of aloes would yield one principle and another description would yield another. He believed that was also the impression which Dr. Tilden had derived from some of his recent investigations on the subject. He had several samples of aloin that had been prepared from different kinds of aloes, and he must confess that they did not appear to him to be absolutely identical. They wanted to know whether the Messrs. Smith claimed that the aloin was the exclusive purgative of aloes, or whether the other parts were equally purgative. There were certain circumstances which seemed to him to suggest that the other parts were equally purgative. The aqueous extract of aloes was considered to be as efficacious as aloes, and yet the aqueous extract yielded little or no aloin. By many the extract was considered as efficacious as aloes and aloin. It would be important if they could obtain larger numbers of samples of aloin from different kinds of aloes, and ascertain how far they were identical.

Mr. A. W. P. Smith said that if aloin was admitted to be active in the doses mentioned by the medical gentlemen in their reports read to-day, if it was active in these doses, how were they to account for anything else being active, because the doses fully accounted for all the activity of the aloes? They had got aloin from all the kinds of aloes, but they confined themselves to the Barbadoes. The aloin that had been found fault with was made from a different kind of aloes than those they used.

Mr. Deane said that from time to time he had been in the habit of examining aloes under the microscope, and had found invariably that the largest amount of crystalline structure was to be found in Barbadoes aloes. Fine samples of Barbadoes aloes varied considerably under the microscope. It was generally a mass of crystals, cemented together by a transparent substance, which was possibly as active as the crystalline portion. In the preparation of aloin he conceived there was a great loss from some change which occurred in the process. For many years he had to make pills of aloin for one or two ladies, and though they could not take aloetic pills, so called, they could take aloin pills with the greatest comfort. From what he had seen there must be great advantage to some persons in the use of aloin. Altogether he thought the subject one well worth further investigation.

Dr. Attfield said he would like to ask the Messrs. Smith or Dr. Cook if they could enlighten the members as to the constitution of aloin.

Dr. Cook said that at present he had no information on the subject; but he hoped they would in time arrive at some kind of chemical decision on the matter.

Mr. A. W. P. Smith said that Mr. Hanbury remarked that Dr. Tilden's idea about the activity of aloin was that it was little used because it was of little use.

Mr. Hanbury.—Little used according to *his* (Dr. T.'s) observation.

Mr. Smith said it seemed strange for those living in the North to hear such a statement, because he did not think there was a dispensing chemist in the whole of Scotland that had not aloin in his stock. It appeared to him that those living in the South were far behind in the matter of aloin.

Dr. Procter said that he had used aloin himself with considerable advantage and success, and greatly to the comfort of his patients; but he must also say that he felt satisfied that the resinous matter had a purgative effect. He had used the resinous matter and had found it to be an aperient. He found that while the aloin acted without any unpleasant feeling, the resinous matter did produce very unpleasant effects indeed.

Mr. A. W. P. Smith.—Is it not possible that in the resin there might have been some active aloin about it?

Dr. Procter.—That seems to be a matter of dispute.

Mr. T. Smith.—It is possible that some of it might have been in it, the resinous matter not being readily exhausted.

Mr. Bottle said it appeared to him that aloin had not the same medicinal effect in the South as it had in the North. Mr. Smith would perhaps remember, twenty years ago, that he called on Mr. Bottle at Dover, and that aloin was introduced there. The use of it was not, however, satisfactory, and he had still the remnant of that very stock which he bought from Mr. Smith. It was possible that he was not supplied at that time with the article which Mr. Smith manufactured now-a-days.

Linseed and Linseed Meal.

BY THOMAS GREENISH, F.C.S.

Although the linseed-meal poultice is by no means a modern invention, yet the first mention of it (*Cataplasma Lini*) occurs in the Pharm. Lond. of 1836, where it is directed to be made with *bruised linseed* (*Sem. lini contriti*), and the same applies to the Pharm. of 1851; but in the Pharm. Brit. of 1867 the terms used are linseed meal, and the explanation which accompanies it is "the cake of linseed, from which the oil has been pressed, reduced to powder." In some establishments to this day a crushed linseed is kept for sale to the public. It has, however, been found that this seed is too rich in oil to be kept long in such a condition, as the oil it contains, when so exposed to the atmosphere, rapidly oxidizes and acquires a degree of rancidity which is very injurious when the poultice made from it is applied to open wounds. In consequence of this defect it has become the custom of the trade to use a much less oily article, which is simply the meal produced by grinding and sifting the dry linseed cake of commerce. The directions respecting this article of the Materia Medica, found in the last edition of the 'British Pharmacopœia,' 1867, attempt to solve the difficulty by directing the *powdered* linseed cake to be mixed with olive oil in the proportion of 2 fluid oz. to the pound when sent out for use, which is necessarily a very inconvenient practice.

In addition to the inconvenience caused by this oxidation of the oil, another has arisen by reason of the impurity or adulteration of the linseed cake, from which the "Lini Farina" is produced, and it is the object of this paper to point out how the difficulties may be avoided, and a true "Lini Farina" be prepared, which, while it keeps well in the pharmacy, will also meet the requirements of the Pharmacopœia, and act efficiently when sold to the public.

It being one of the objects of this Conference to direct attention to adulterations, it becomes the duty of its members to point them out, and, if possible, to prevent them. This remark applies with force in the present case, as the "Lini Farina" enters into the composition of no less than five preparations of the British Pharmacopœia.

The result of any investigation of this subject must necessarily be imperfect without a reference to the history of the linseed as imported into this country. Russia is the great linseed-producing country of Europe; and previous to the Crimean War our supplies were almost entirely drawn from St. Petersburg, Archangel, and other ports of the North; also from Odessa, Taganrog, and other ports on the coast of the Black Sea in the South. But during the Russian War these ports were blockaded, and the difficulty then experienced in obtaining the required supplies led to considerable importations from India; and such an impetus was thus given to the growth of linseed, that the quantity now imported from the East is larger than that received from Russia, which has never fully recovered her trade.

Even before the war, linseed had always more or less of foreign seeds mixed with it, and was shipped in a very impure condition; but it was during the scarcity caused by the war that it became so very much adulterated, and the principal seat of that adulteration was Odessa.

At that time there existed in this country no institution for checking the growing evil, but this check was ultimately provided by the formation of the "Linseed Association of London."

(Samples of linseed were shown as imported previous to, and during the war, to illustrate how loaded it was with impurities.)

There must necessarily be found mixed with every kind of linseed a certain amount of wild seeds gathered during the operation of harvesting. This is especially the case with "flax dodder," which is a parasitical plant; but as all, or nearly all, the accidental seeds are smaller than the linseed, proper screening should remove them.

Careless harvesting and positive adulteration had, however, reached such a pitch that, in 1864, importers and crushers founded an association called the "Linseed Association," and agreed in future to buy and sell on L. A. terms, which were that 4 per cent. only of admixture should be allowed, and that all beyond that proportion should bo more or less a loss to the merchant. These terms were soon understood and conformed to by the shippers; and there is consequently, at the present time, no difficulty in procuring linseed almost pure; neither, on the other hand, is there any difficulty in procuring linseed with a large admixture of weed seeds, for at the present time Riga and St. Petersburg seed, and probably others, may be purchased without reference to L. A. terms; and, when it is understood that there are sometimes from 12 to 15 or 20 different foreign seeds mixed with the linseed, and that the whole adulteration may amount to 30 per cent., it will be seen how wide a margin there is left for unscrupulous crushers of linseed.

(Samples were exhibited showing a great improvement in linseed imported after the L. A. was established.)

It will also be observed that there exists much difference in size between the Russian and the Sicilian or East Indian linseed. The linseed grown in a tropical climate does not produce so fine a quality of oil, but it yields a larger amount of farina, and makes a more nutritious cake, and of the different samples of East Indian linseed before you, that from Bombay has the preference. The small seed grown in a cold climate, however, yields the linseed oil most esteemed by painters and varnish makers for its excellent drying qualities.

It is in the East Indian linseed, the best for its farina, that the wild rape and wild mustard are found, usually not alone, but mixed with grass seeds, and it is to these pungent seeds of the Natural Order *Cruciferæ* that our especial objections apply, the volatile oil being developed on the addition of the hot water necessary to form a poultice.

[There are here samples of flax dodder found chiefly with seed from the Russian ports; also wild rape, wild mustard from the East Indian linseed, and others, probably grass seeds.]

It would be well for those who reside in agricultural districts and may be called upon to examine linseed-cake, to make themselves especially acquainted with the microscopical characters of linseed, and for that purpose I cannot do better than refer them to some interesting remarks on the subject in the PHARMACEUTICAL JOURNAL, February 18, 1871, page 663, by our President Mr. Stoddart.

I will just mention here a case where the agricultural mind has been imposed upon. Wild charlock or corn-mustard seed, of little or no value, is mixed with turnip seed (which it much resembles), and is then sold as genuine turnip seed, but, previous to its being mixed, it is subjected to a temperature sufficient to destroy its germinating property. When the mixed seed is sown, the turnip consequently only comes up, and the fraud is not discovered, "for dead men tell no tales." Charlock is usually met with in English linseed, which is not used by crushers.

The ordinary linseed-meal of commerce, as I have previously remarked, is usually made by grinding and sifting a very dry linseed-cake; this is generally an imported cake, as English-made cake always contains water, whilst the foreign cake must have been thoroughly dried to have stood the voyage without becoming mouldy or heated. Fresh English linseed-cake ordinarily contains 10 per cent. of water, and such a cake, if ground into meal, would not keep well. The foreign cake is chiefly imported from New York and Marseilles.

In the United States linseed is pressed for its oil as it is here; the consumption of linseed-oil in that country being greater than the home supply, it is supplemented by purchases of oil made in England, but the cake is not used for fattening cattle to the same extent as it is here, consequently they are able to export cake for the English market; they are thus buyers of oil and sellers of cake.

This imported and impure cake is the material from which the ordinary linseed meal of the shops is prepared, and though largely and extensively used, does not fulfil the requirements of British Pharmacy. Its price, one-half that of the pure farina of crushed linseed, is a sufficient indication of its character and quality. Sometimes the farina of crushed linseed is mixed with this cheap meal so as to reduce the price, and the mixture is thus sold with a semblance of purity.

The conclusion at which I have arrived is, that most of the linseed-meal of commerce does not come up to the required standard of the Pharmacopœia. On the other hand, a great deal of that which is commercially pure is not elegant, containing either too much oil or too large a quantity of husk, sometimes both, and that which is the produce of foreign cake can never be relied on, inasmuch as it contains irritating matter, which has in many instances on record resulted in considerable mischief.

To produce a good "Lini Farina," the linseed (preference having been given to that from Bombay or Sicily) should, after being passed through the rolls, have a portion of its oil expressed without heat, then be ground, and afterwards have the husk sifted out; the resulting farina, when mixed with hot water, will then assume a gelatinous consistence, and be quite free from volatile pungency such as that of mustard, and, if kept in a cask lined with tin, it will remain good for several months. This, in my opinion, is the "Lini Farina," best adapted for a linseed-meal poultice, a therapeutic agent seldom properly made, generally despised, but for which there has not yet been introduced an efficient substitute; and I trust that some crusher who may have his attention drawn to the contents of this paper will make it his business to prepare a "Lini Farina" for pharmacists in conformity with these suggestions.

In conclusion, I would submit for your examination, samples of true lini farina, pure English cake, good American cake, inferior American cake, from which the meal is ground and the linseed-meal of the shops.

The CHAIRMAN said that his experience rather astonished him. When he went to the West of England first, in Worcester, the rate was threepence for linseed and sixpence for linseed-meal; but when he got to

Bristol the rate was sixpence for linseed and threepence for linseed-meal. The quantity used in Bristol he would back against any place. With regard to adulteration, linseed cake was awfully adulterated. He had no hesitation in saying, from his experience of analytical work, that it was adulterated to the extent of at least fifteen per cent.

Mr. Bell said that there was more linseed imported into Hull than into any other town in England, and perhaps there was more adulteration there. Linseed cake was frequently adulterated with buffum. He had great objection to using linseed meal on account of that. With regard to crushed linseed, his experience told him that it was the best. He bought it in small quantities, and it kept its properties to the last.

Mr. Deane said that for a long portion of the time he had been in business he had been in the habit of using the ordinary ground cake, believing it to be the thing that was intended to be used, but a few years ago a curious circumstance occurred. He gave to a person, for a domestic purpose, some linseed-meal, and in the course of some days he was told that where any portion of the poultice had fallen on the patient it produced a blister. On making inquiry into the subject, and a careful examination by the microscope, he found that the mischief arose, as he believed, through the mixture of Cruciferous seeds which the linseed contained. Probably these were not seeds put in intentionally, but arose from careless culture and careless dressing. They formed part of the crop, and had been sent out without regard to consequences, because they added to the bulk. He had been in the habit for many years of using crushed linseed, taking care to have it in such quantities that it would not spoil by keeping. It was a curious circumstance with regard to the seeds grown in some parts of Europe, that they made the finest oil for painters, provided they were not contaminated by those wild seeds. From all he knew about linseed, he thought it should make all chemists very careful as to what kind of linseed they made use of. He was quite satisfied that if the linseed-cake was genuine—ground cake, free from contamination—it made an excellent poultice and kept better than the other. But as there was difficulty in getting that, it was better to get the crushed linseed from a respectable house rather than run the risk of getting meal from cake, the history of which they knew nothing about.

Mr. Atkins said that he could testify to the large amount of meal consumed in the West of England. The ordinary linseed-meal or crushed cake cost about 14*s*. per cwt., and the crushed linseed about 32*s*. The retail price at Salisbury was 4*d*. for linseed-meal and 6*d*. for linseed, whole and crushed.

Mr. Collins said, with regard to the linseed they had from India, that there was great carelessness shown in the docks. They would find rice-seeds and all other kinds of seeds amongst it; and very often when the men were turning the sacks the seeds fell down and were freely mixed. Very often the bags were made so loose in texture, that various kinds of seeds fell through and mixed with the linseed. That was one of the reasons why the Indian seed was so much complained of through the packing in the ship's hold.

Mr. Bottle said he had found difficulty in getting the proper linseed meal. He had discarded it and purchased crushed linseed.

Mr. Mackay said that the pharmacist had no reason to go away to the West of England in order to get a really good linseed-meal. Some years ago he was a good deal bothered about this article. It was not unlike the American meal, and the dreadful thing was it had this peculiarity, that it was so hard that the ordinary means of making it into a poultice were unsuccessful, and the hardness of the particles caused a great deal of trouble, annoyance, irritation and even pain. He tried many places; he even went to England, and the experiences he had were exceedingly unsatisfactory, until he fell on crushers of seed not far from Edinburgh, Wacklin, Ruddock, and Co., and from experience he could say that their linseed-meal was very good, and 5 per cent. cheaper than in some other places. If pharmacists applied to that firm for a sample of their linseed-meal, he had no doubt that they would be satisfied.

Mr. Hanbury said that during his business experience in London, the firm with which he was connected used to keep the crushed linseed and the powdered cake, but the latter was scarcely ever required.

Mr. Frazer said that in Glasgow, considerably above twenty years ago, the crushed seed was first brought under his notice by a Liverpool house. He found it to be a genuine article and at once introduced it. He had since then ceased to keep the article made from the cake; and, notwithstanding its higher price, had found the public gave the crushed seed a most decided preference.

Mr. Greenish considered that the objection urged against "crushed linseed," that it oxidized very rapidly, was met by the sample on the table, from which a portion of the oil had been expressed, and in that condition, if properly kept, it would remain good for a reasonable length of time. As to Mr. Collins's remark with reference to admixture at the docks, all he could say was that it had not come under his notice.

Mr. Collins stated that in the docks he had seen it to a considerable extent.

A Member said that he thought they would like to know the results of the crushing of the seeds, with reference to the amount of oil that was given off by the different seeds which came from the various countries. If these had been given, the paper would have been more valuable. There was an old article of domestic use called carron oil. Could any member inform him whether linseed-oil had been used for the manufacture of that? It would evidently affect the carron oil if it contained many of these seeds. It was still much in use and more preferred in domestic use than the finer article, olive oil.

Mr. Deane said that linseed-oil made a sort of paint, olive-oil did not.

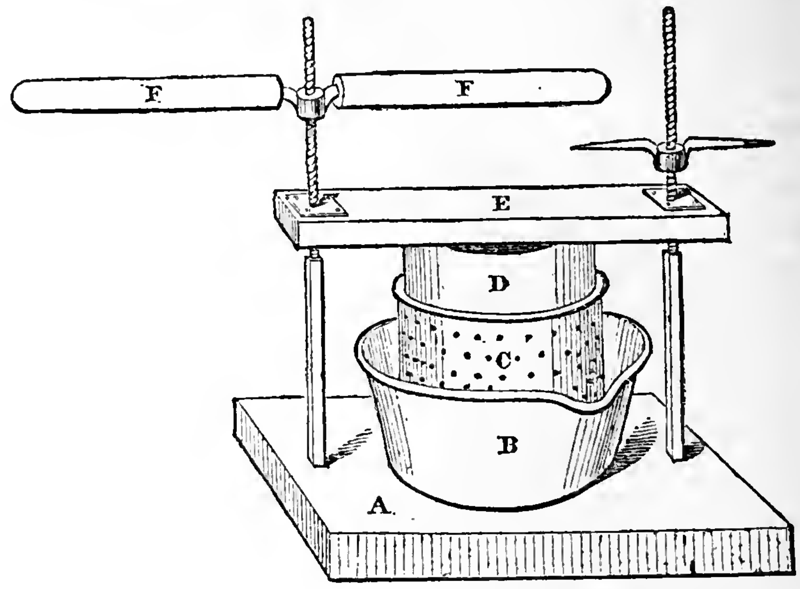
Mr. Greenish, in reply, said the average quantity of oil in linseed was from 25 to 30 per cent., and probably 10 per cent. of that would be pressed out in making the farina. With reference to the quantity of oil from different seeds, those from Bombay and Calcutta yielded a much larger quantity than the Russian seed, but any reference to this point would involve a larger subject and have no practical bearing on the present question.

Dr. Attfield read a paper on

The Tincture Press.

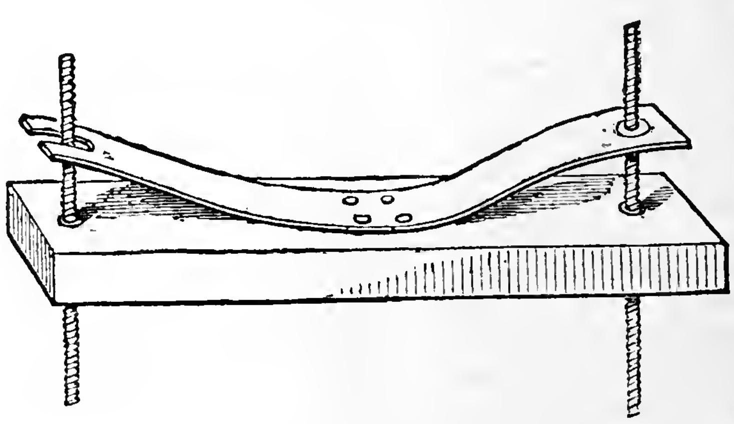
BY C. A. STAPLES.

The tincture press is one of the most important implements in the pharmaceutical laboratory. Without its judicious use, not only would the loss of tincture be very great in quantity but in quality also, the latter portion of which is obtained by the press being the richest in extractive matter. Indeed, the preparation does not fairly represent the Pharmacopœia article until it has been thoroughly expressed, and the products mixed together. Such being the value and importance of the tincture press, I have often felt surprised that so little improvement has been made in it. The workmanship has certainly been brought to a degree of perfection that cannot fail to command our highest admiration, but the faults remain. The first defect that strikes the intelligent mechanician is the severe torsion of the screw. The implement is usually constructed with a powerful cast-iron frame, in which the female screw is fixed, the male screw being turned by a lever. The effect of this method of applying the power is a tendency to force the screw out of the perpendicular. But it would bear a much greater power without injury if such power were applied to the female screw or nut. To make myself better understood, imagine a wire hanging from a beam, load it, and notice the enormous weight it will bear without injury. Now reverse the position, and try to support the weight at the top, it will require a much stronger wire to act as a pillar, or it will bend and the weight come to the ground. Now this may be compared to the screw of the press: the power applied being usually expressed as equivalent to so many pounds weight, this is sometimes enormous, and will be understood by the following simple calculation. In a small screw press, such as is usually found in the pharmaceutical laboratory, the lever radiates from the centre, say 12 inches, it would travel a circumference of over 72 inches for each revolution of the screw. Now place the rule to the screw, and note the number of threads to the inch; if 6, this would give $72 \times 6 = 432$, as the number of inches the lever travels for each inch of pressure obtained; that is to say, the power is multiplied 432 times. Now if we imagine a force equal to 100 lbs. applied to the end of the lever (and this is but a moderate estimate of a man's strength), it would give $432 \times 100 = 43{,}200$ lbs. as the weight, such pressure would represent; or, we may compare the screw of the press to a column supporting a weight of nearly *twenty tons!* How is it to support this prodigious weight? Evidently only by increasing its bulk, and consequently the friction, cumbersomeness and expense of the implement. It may be objected that these figures are somewhat theoretical. I use them as an example of the laws by which the force of mechanical powers is usually computed, but I am sure it will be readily conceded that if well applied, the power of a good screw-press is very great, and that if cases do arise where it fails to meet the requirements of the pharmaceutical laboratory, they must be extremely rare. The next defect to be noticed in the iron frame press is its rigidity; the pressure ceases the instant the hand is taken from the lever; now to bring the expression of a large mass of tincture to a successful and economical termination will occupy several hours, during the whole of which time it should be subjected to a steady, firm, but elastic pressure. At first it must be very gentle, or the substance will be forced through the holes or the cylinder burst open, but as the process advances, more pressure should be applied, and gradually increased until the full power of the press is brought into use. Now it is evident that this uniform pressure cannot be obtained by an implement, the excellence of which consists in the firmness of its parts, without the uninterrupted labour of some one with his hand on the lever to keep the pressure constantly applied, requiring an amount of time and labour that would add greatly to the cost of the production, and that might be saved by an improvement in the machinery. The next defect we observe is, that an additional vessel (generally an evaporating basin) has to be used to receive the expressed juice as it flows from the spout at the bottom of the cylinder; this may appear a trifle, of which it is frivolous to complain, but where the press is portable, it sometimes causes considerable annoyance and loss. The assistant endeavours to steady the press with his foot, from which it frequently slips, and the basin may be overturned or broken, and the product wasted. Taking all these defects into consideration, and thinking that my slight mechanical knowledge might enable me to design a press in which some of them would be remedied, I drew a rough sketch of my idea, and had the parts manufactured in a simple inexpensive manner, so as to produce a working model, from which I purposed constructing a more perfect and highly finished implement when I had discovered and corrected the faults which only experience could detect. I have endeavoured to represent it as it appears, but I am not a draughtsman, which I trust will be my apology for the rudeness of the sketch.



A is a strong platform of oak plank, into which two square iron bolts secured by broad flat heads are firmly fixed, rising perpendicularly to it, and parallel to each other, and having a screw-thread cut in them about half their length. B is a spouted basin of tinned plate to receive the expressed juice. C is the cylinder of tinned iron plate pierced with fine holes. The block D, of turned wood covered with tinned plate, is forced into the cylinder by the wooden cross-beam E, which has a hole at each end, through which the screws pass, large enough to allow it to slide freely up and down the screws, and armed with a piece of polished iron plate to diminish friction. The power is applied to the nuts or female screws, polished at the bottom and furnished with wooden handles FF, these are purposely omitted at the right to show the form of the nuts as forged by the smith. The cylinder holds half a gallon. I have also one holding about 1 pint. Several of them of various sizes might be used by the same press.

This simple inexpensive implement possesses many advantages; it is light and portable, works easily, has very great power, and as the power is applied in the best manner, the strain is very slight, and the friction less than would be expected. I have had it in use about fifteen years, it has never got out of order, or required any repairs (excepting an accident from undue violence). Of course it would be better if the workmanship were more highly finished (*e. g.* with steel screws substituted for iron), but as my old model is still in such good working order, I have not yet replaced it by the more perfect implement, or discovered the faults that I expected I should have to correct. The only improvement I can suggest is the increase of its elasticity; and this I would propose to accomplish by a powerful steel spring screwed to the centre of the cross-bar, and rising a little from it at each end, somewhat in the form shown in the sketch.



Sketch of proposed Spring.

Without experience I am not prepared to give the exact size and substance of the spring, but I think it should be about 2 inches broad, $\frac{1}{4}$ inch thick in the centre, decreasing to about $\frac{1}{8}$ at the ends. The holes through which the screws pass would be elongated or a slit filed at the end of the spring, care being taken to give sufficient space for it to rise and fall without injury to the screws. In my opinion the spring would effect a great saving of labour. The first effect of the power would be to depress the substance in the cylinder; this offering resistance, further power would force the spring down to the cross-beam. The press being now set aside, the spring would continue to act upon it, the action would thus be somewhat automatic. For a very large press, probably a compound spring (on the principle of the coach-spring) would be required.

Mr. Greenish, Mr. Savage, Mr. Newbiggin and others made a few remarks on the construction of the press, and a general approval was given of it.

Parliamentary and Law Proceedings.

The Alleged Attempt to Poison by a Lady.

On Thursday, August 31, Christiana Edmunds was again brought up on remand before the magistrates at Brighton. The solicitor for the prosecution said that he should on that occasion enter specific charges against the prisoner charging her with attempting to murder Mrs. Beard, the wife of Dr. Beard, and also with attempting to administer poisons with intent to do bodily harm to Mr. Garrett and Mrs. Boys. Since the last examination it had been proved that the prisoner had sent a letter for three ounces of arsenic to a chemist named Bradbury, who had now left the town, and whose successor had given the letter up. Mr. Bradbury was being searched after. The letter had been identified as in the handwriting of the prisoner, though signed as by "Mrs. Wood," the name given by the prisoner to Mr. Garrett to obtain the strychnia.

Mr. Henry Swaysland, son of a bird-stuffer in Queen's Road, Brighton, was then called, and stated that he fetched the body of a dog from 16, Gloucester Place, which he gave to Mr. Brazenor.

Mr. Brazenor, bird-stuffer, Lewes Road, said he took the body of the dog in question from last witness, and on opening it, found that the dog had been poisoned. His reason for believing that the dog was poisoned was because its limbs were very limp, and the vertebral column was bent inward. There was a peculiar smell about the dog's throat and lips, and a large quantity of saliva about the mouth. He could not state what poison was used, but was certain it was not prussic acid.

Mr. J. Netherclift, of 18, Golden Square, London, an expert in handwriting, was then called, and said he had examined the writing on the outside of the paper sent to Mrs. Beard, and also on the wrapper in which the cakes which were sent to her were enclosed, and he identified the handwriting as being the same as that of letters of the prisoner. The letter addressed to Mr. Garrett was also in her handwriting, and also a note addressed to Mr. Curtis.

Mr. S. P. Blaker, surgeon, said that he had attended Margaret Knight in her illness, and placed some vomit in two bottles, which he carefully sealed up, and delivered to Inspector Gibbs.

Inspector Gibbs deposed to delivering the bottles to Mr. Rogers, on the 21st of last month, numbering them two and three. He also delivered some cakes, which he received from Mrs. Beard on the 13th, to Professor Rogers, and also some preserved fruit.

Professor Rogers, examined by Mr. Stuckey, stated that Inspector Gibbs had delivered to him the vomit in two jars, and also a parcel of cakes and some preserved fruit, and a handkerchief. He had analysed all these articles, and partly tested the handkerchief. Jar No. 2 contained arsenic in most decided quantities, and the jar No. 3 also contained arsenic, but in smaller quantities. The handkerchief gave traces of arsenic. There was no other poison in these three articles. If the first vomit had been examined, he had every reason to believe that it would have been found to contain more arsenic than there was in either of the two jars he had examined; did not think there was sufficient in jar No. 2 to destroy life; but it was enough to be highly injurious. It was the common white arsenic that was used. On examination of the cakes he found that one of them had on it a dangerous quantity of arsenic. The arsenic was sprinkled over the cake. A second cake contained arsenic on it in the same way, but less in quantity. On two other cakes and some fragments there were mere traces of arsenic. There were several grains of arsenic on the first cake, and it was his intention to state, on a future occasion, the exact amount. All the four preserved fruits had arsenic on them, and one was literally stuffed with it. The arsenic found in one was enough to have destroyed the life of any one. Witness here stated that he had also examined two peaches which had been sent to Mr. Garrett, and found they had been covered with strychnine. The peaches were very much decomposed, but there was strychnine all over them. The quantity was, he believed, sufficient to have caused death.

Mr. Netherclift was recalled, and stated that a letter, which was found at the residence of Mr. Bradbury, was in the same handwriting as the other letters.

Mr. Thomas Glaisher, of the firm of Glaisher and Kemp, was then shown a letter, which he stated was not written by him or by any one in his establishment. The letter was one sent to Mr. Garrett, purporting to order a quantity of arsenic.

Mr. Black, coroner of Brighton, stated that the letter produced was not in his handwriting, and was not written by his authority. The letter purported to come from him, and requested Mr. Garrett to send his "Sale of Poison Book."

Emma Helsay: She was parlour-maid to Mrs. Boys, 59, Grand Parade. She recollected a parcel coming by a railway van on the 12th of August, addressed to Mrs. Boys. On the following day she was in the housekeeper's room, and saw the nurse taking some cakes from a box like the one produced, and putting them in a dish. There were two gingerbread cakes, two cheesecakes, two macaroons, two plum-cakes and two tartlets, done up separately for Mrs. Boys. A piece of thin paper was wrapped round these. The nurse broke in half one of the tartlets in the paper addressed to Mrs. Boys, and they ate half each. About ten minutes after she felt very sick, and had a burning in the throat. Her legs ached, and felt drawing up. Those sensations lasted until ten o'clock that evening,—about eleven hours,—when she began to get better, but it was nearly a week before she felt herself quite well. The nurse was very unwell—much worse than her.

Mrs. Boys then deposed that there was also in the box a piece of paper, which she tore up; on it were the words, "I send you some cakes for your two little girls. Those directed to yourself are my first efforts. I hope to see you soon.—Your old friend, G. N." Witness put the box into the garden-room, and the next morning gave it to the nurse of the two younger of witness's little girls. On the morning of the day after the parcel arrived she was sick two or three times. In consequence of the child being so unwell, and the nurse and parlour-maid unwell also, she gave certain directions to the cook with reference to the box; one of the tartlets was preserved, and in the afternoon she took a portion of it to Messrs. Glaisher and Kemp's; the other portion of the cake she gave to Mr. Blaker. Witness did not eat any portion of the cake herself. Had never seen the prisoner before, but was in the habit of visiting at Mrs. Beard's.

Amelia Mill, nurse to Mrs. Boys, said: On the 11th of August she received some cakes in the box produced from Mrs. Boys. She ate part of one of the tartlets, and about a quarter of an hour afterwards she felt very sick, and about one hour afterwards she was taken very sick indeed. She felt a burning sensation in the throat and chest. Her sickness continued all the afternoon and evening. She felt very giddy, and trembled very much for three or four days. She continued very ill. Mr. Blaker, the doctor, saw witness about eleven o'clock that night, and was in attendance on her for nearly a week; it was quite a fortnight before she recovered. Both of Mrs. Boys' children had a part of one of the currant cakes; the younger child, five minutes after eating the cake, became very ill; the other child only had a very small piece of the tart, and after dinner she looked very pale and ill. Witness was obliged to make her lie down. Both the little girls were in good health before they partook of any of the cake.

Mr. Blaker, M.R.C.S., stated that he was sent for by Mrs. Boys on Friday, the 11th, to see the nurse and parlour-maid. The nurse was constantly vomiting, and was suffering from pains in the stomach, and, to use her own words, was "indescribably ill." Witness attended the nurse for more than a week. From the symptoms, he believed that she was suffering from an irritant poison, which he believed to be arsenic. He had a piece of one of the cakes given to him by the cook, which he put on the top of a high press in the kitchen. He received from Mrs. Boys a portion of a cake, which he took to the dispensary at the hospital. It had a substance upon it which looked like sugar. Subsequently he received it back from the dispenser, and handed it to the inspector of police.

Mr. Smith, dispenser at the Sussex County Hospital, said that on the 12th of August he received a package from Mr. Blaker, containing some cake. He analysed fifteen grams of the cake for arsenic, and found it to contain five decigrams and eight centigrams; of sulphide of arsenic, between seven and a half and eight grains. This was a sufficient quantity, in his opinion, to destroy life.

The case was then adjourned.

The prisoner was brought up again, on remand, on Thursday, September 7th.

Evidence was then given tracing a piece of cake from Mrs. Boys to Messrs. Glaisyer and Kemp, and from them, through Inspector Gibbs, to Professor Rogers.

Professor Rogers said:—He remembered receiving several packets, numbered 5, 6, and 7, from Inspector Gibbs. He had analysed their contents. Each packet contained a piece of cake, and each piece of cake contained a quantity of arsenic, a dangerous quantity. The piece of cake in packet No. 7 weighed 57 grains, and of that there was about a grain and a quarter of arsenious acid, or white arsenic. The arsenic was in the proportion of eleven grains and two-tenths to an ounce of cake. He could not state whether the arsenic in this specimen had been mixed with the cake before it was baked, as it was much crumbled up.

Mr. Samuel William Bradbury was then called. He stated that he resides at Alton, in Staffordshire. In July last he had a shop at 21, North Road. About the 21st of that month he received a letter of that date (now produced). It was enclosed in an envelope, and was delivered by a boy at his shop. He did not know the boy. He supplied the article ordered in the letter—three ounces of arsenic.

Mr. Netherclift stated that the letter was in the same handwriting as the others. [The letter, which was read, purported to be from Messrs. Glaisyer and Kemp, and requested him to supply them with three ounces of white arsenic, of which they were in immediate want, and to send it by the bearer.] The witness continued—He wrapped it in three papers and gave it to the boy, who tendered him a shilling. He charged three-halfpence for the arsenic, and the boy took it away. Did not know the boy.

It having been intimated that the prisoner would reserve her defence, she was then committed for trial on the charge of attempting to poison Mrs. Beard.

The prisoner was then charged with causing the death by poison of a boy named Sidney Albert Baker. The evidence given was, to a great extent, similar to a portion of that brought forward at the inquest on the boy and already reported (p. 17). In addition two boys were produced, who said that a lady, whom they believed to be the prisoner, had sent them to Mr. Maynard's to purchase creams. On their return with the creams the lady had told them they had brought the wrong sort, and sent them back to change them. The theory put forth by the prosecution was that the lady in question was the prisoner, while in her possession the creams were tampered with, and that they were afterwards returned to Mr. Maynard, and placed by him with his other stock.

Dr. Letheby said he had analysed the chocolate creams given him by Inspector Gibbs. They contained a great deal of strychnia, generally in the proportion of 5 grains to the 100. The minutest portion would be extremely bitter. Each of the large chocolate drops contained five or six grains. One grain might be regarded as a fatal dose, but half a grain has been known to destroy life.

The prisoner was then further remanded till the next day.

Poisoning by a Lotion of Corrosive Sublimate.

An inquest was held a day or two ago by Mr. Kemm, coroner, at Elm Grove, Chippenham, the residence of Mr. R. N. Fowler, M.P., touching the death of Mr. Fowler's daughter, Harriet Maria, a child nine years of age. Mr. Goldney, M.P., was foreman of the jury. Mr. Keary, solicitor, of Corsham, attended to watch the proceedings on behalf of Mr. Fowler, and Dr. E. M. Meeres, of Melksham, under whose care the deceased had been placed, was also in attendance.

Elizabeth Saturley, nurse, said that on Friday, the 1st inst., the deceased died at about a quarter to eight in the morning. On Monday, the 21st August, witness had taken her to Dr. Meeres, at Melksham, to have her head examined. He said she had ringworm, and gave her a lotion to wash the head with twice a day, and some medicine. She applied the lotion and gave the medicine as directed. Dr. Meeres called on the Wednesday following and ordered the head to be shaved, which was done the following day, and the lotion and medicine were continued as before. On Monday, the 28th, Dr. Meeres saw deceased at the house, and said witness was to have her head washed, and to take her to him at Melksham in the afternoon, and he would put an application to the head that he hoped would kill the disease at once. She took deceased to Dr. Meeres' house, and he applied a liquid from a bottle with a small brush, and cautioned the deceased not to open her eyes. He said if a little ran down her neck it did not matter. Some of the liquid ran down the neck behind the ear. The application gave the deceased no pain at the time. Witness brought her home in an open dog-cart almost immediately. During the journey she suffered great pain, and she appeared in great pain after reaching home. Witness applied cold cream and cold water to her face, but did nothing more until Dr. Meeres had seen her again the same evening. He seemed surprised to see how much the head and face were swollen in so short a time. Deceased continued in great pain all night. The next morning they sent for Dr. Meeres, and he ordered cold water pads to be applied over the eyes and forehead. He was asked if there was any danger, and he assured them there was not. Deceased still got worse, and they told Dr. Meeres they should have further advice. They telegraphed for Mr. Gore, of Bath. Mr. Gore and Dr. Meeres saw deceased together about five o'clock in the afternoon on that day. The swelling continued to get worse, and deceased got no sleep on the Tuesday. She was constantly inclined to be sick, and took no food on Wednesday. The head began to blister the same evening as the lotion was applied. Mr. Gore ordered tepid water pads to be applied. On Wednesday evening Dr. Meeres gave deceased a composing draught about five o'clock, and about ten o'clock witness gave her another. The deceased slept about two hours that night. All day Thursday she seemed very drowsy, and also on Thursday night. About a quarter to eight on Friday morning she died. On being cross-examined by Dr. Meeres as to whether she seemed surprised when he came, witness said he did. Witness also said he made use of the expression, "He did not care about the liquid running down the neck." The mouth was very much swollen, which prevented deceased taking any solid food. Her lips were also swollen. She could swallow liquids. After Mr. Gore's visit some other medicines were ordered, which she took.

Mr. R. T. Gore, of Bath, said that he saw the deceased first between five and six o'clock on the afternoon of Tuesday, August 29, in company with Dr. Meeres. The head and face were a good deal swollen, and there were remains of blisters on the head and on the neck. There were also some spots on the head and face, apparently the remains of an eruptive complaint. The gums were somewhat swollen and tender. Dr. Meeres told him to what circumstances the appearances were to be attributed, viz. that he had applied a strong lotion of corrosive sublimate on the day previous. Witness said he rather regretted the strength of the application that had been made, as from experience he knew such applications were not free from danger. He did not see deceased again alive, as he was from home on Friday when sent for. From the blistered state of the head when he saw it, it was impossible to distinguish the exact nature of the eruption. He thought the swelling of the mouth and head, and the general symptoms, were undoubtedly occasioned by the application, and were the effects of an over-strong application of such a remedy. In cases where there were abrasions of the skin, such applications would often produce not only local symptoms, but general symptoms of poisoning, such as those in the present case were. He considered that the corrosive sublimate used was undoubtedly the cause of death. He did not at first know the strength of the application, but he afterwards found it was a very strong one.

Dr. Meeres requested permission to make a statement on oath to the jury, as he thought himself the person best acquainted with the case, and most deeply interested in putting the whole of the facts candidly before them. He was cautioned by the coroner as to the possibility of any statements he might make being used as evidence against him. He then said that on that day fortnight the deceased was brought to him at his house. She was then suffering from ringworm. At first he gave her a tonic, and a lotion to wash the hair. As it seemed to spread, he ordered the head to be shaved, and the previous treatment was continued until last Monday, when he found the ringworm was spreading over the head. He requested her to be brought to him in the afternoon, for the purpose of using some application to destroy the ringworm, which was a sort of fungus in the skin. On the Monday when she was brought to him he applied, with a brush, a solution of bichloride of mercury, commonly called corrosive sublimate. The formula was taken from Dr. Tilbury Fox's work on skin diseases. He took the book to the chemist, Mr. Laine, of Melksham, and ordered him to make up the prescription according to the formula given therein. The mixture was made specially for this case on the Monday, and the strength was ten grains to the drachm, or eight grains to the ounce, dissolved in alcohol. The effect of this application was always to blister, and it was intended to do so. According to Dr. Fox it was never absorbed into the system, but the effect was always local. In the present case, unfortunately, the mixture by some means got into the system and produced salivation. He had on some previous occasions used the same application, which he made up himself. He was present when the chemist made up the mixture, and he saw the ingredients weighed out and gave him the printed formula to go by. There were some scratches about the forehead of the deceased which he avoided in applying the lotion. He was satisfied none went into the abrasions, but if it had, no ill effect would have followed, as the effect of this strong application was to coagulate the blood at once. He knew it would cause a blister, but he had no recollection of having told the nurse that if some went on to the neck of the deceased it would not matter. If it had gone into the eye it would probably have blinded it. The previous lotion was quite innocuous, and was given merely for the purpose of cleansing the head. He continued to attend the deceased until her death. On Thursday night he thought the swelling of the mouth was abating. There was no doubt the mercury by some means got into the system and produced the symptoms described. He had applied the same mixture and the same strength to children of about eight years of age. No mercury was given internally in the present case.

After clearing the room the jury unanimously concurred in the following verdict:—"That the said Harriet Maria Fowler came to her death on the first day of September instant from the effects of poison caused by a very strong preparation of bichloride of mercury having been applied to the head and neck of the deceased by Dr. Edward Evan Meeres, on the 28th of August last past, whilst under his care for an eruption on the head; and the jury are of opinion that great blame attaches to the said Dr. Edward Evan Meeres." The coroner and jury expressed their condolence with Mr. and Mrs. Fowler on the melancholy occurrence.—*Daily News.*

Extraordinary Charge of Manslaughter against a Chemist.

On Thursday, August 31, the magistrates at Sidmouth were engaged in investigating the charge against Mr. Robert Webber, chemist, for feloniously killing and slaying William Wall, Esq., at Salcombe Regis. Evidence was given that in the latter part of July deceased sent a prescription of an opiate to defendant to make up. Defendant sent a mixture, but five minutes afterwards discovered he had made a mistake, he having put twenty grains of morphia, with directions that half was to be taken at once. He immediately despatched messengers to Mr. Wall's house and sent for a doctor, but before either reached the place the deceased had taken half the quantity as directed, so that when the doctor arrived the deceased was senseless. Efforts to arouse him were fruitless, and he died five hours afterwards. At the inquest the jury did not think the defendant's carelessness sufficient to constitute manslaughter. The Home Secretary, however, had taken up the affair, and ordered the present magisterial proceedings.

Medical evidence was called to show that there must have been great carelessness to make such a mistake; whilst another doctor said, although he himself should not have made the blunder, yet it was quite possible that a person might have made even a worse mistake, as the writing of the prescription was very bad.

The Defendant was committed for trial for manslaughter.—*Standard.*

Attempted Suicide by Essence of Almonds.

At Worship Street, on Friday, September 1, Flora Warner, a servant in the employment of a City company, was charged on remand with having attempted to commit self-destruction by taking a quantity of essence of almonds. The facts of this case were of a most painful nature. The prisoner held a respectable situation, and was much respected. Her employers gave her a holiday on the morning of the Foresters' *fête* at the Crystal Palace, so as to afford her an opportunity of going there with a party of friends. About eight o'clock the following morning she was seen by a watchman in Holywell Lane, Shoreditch, in the act of taking something from a phial which she raised to her mouth. He called the attention of a police-constable to her, and she was removed to the surgery of Dr. Phillips, in Spital Square. There an emetic was administered, and she got better. The phial taken from her hand was labelled "poison" in large letters, and after the prisoner had been remanded a summons was ordered for the attendance of the doctor who sold the stuff to the prisoner. He was now present, but his name did not transpire. In reply to the magistrate, he admitted selling the poison in the bottle produced, which he said held about half an ounce. He could not say if the quantity sold was sufficient to destroy life, but the bottle was not full. It was essence of almonds. He had questioned the prisoner, and she had stated that she wanted it to flavour jellies, etc.

The magistrate remarked, that it was necessary to know how such poison came to be sold, but he had been under the impression that it was oil of almonds, and not essence.

The doctor said that he should not have sold oil of almonds to the prisoner without she had been introduced to him by some one he knew, but essence of almonds was an article of daily commerce, and much used by pastry-cooks, etc., for flavouring custards, blancmanges, etc.

The magistrate then ordered the prisoner to be given up to her father, who was in attendance, and who promised to take care of her.—*Daily News.*

Accidentally Poisoned.

At the adjourned inquest, held on Wednesday, 23rd August, on John Bullock, the old man who was accidentally poisoned at Aston on the 25th of July, the jury considered that Hunter was highly censurable for his carelessness, and that Mr. Hoare was also blamable in not attending to Bullock immediately when called in.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

APPOINTMENT.

Mr. Theophilus Weaver, A.P.S., late Dispenser to the South Staffordshire General Hospital, Wolverhampton, has been appointed Dispenser to the Birmingham New Parish Dispensary.

BOOKS RECEIVED.

On the Relative Powers of various Substances in Preventing the Generation of Animalcules or the Development of their Germs; with Special Reference to the Germ Theory of Putrefaction. By John Dougall, M.D. London: J. and A. Churchill. 1871.

Analytical Tables for Students of Practical Chemistry. By J. Campbell Brown, D.Sc., F.C.S. London: J. and A. Churchill. 1871.

The following journals have been received:—The 'British Medical Journal,' Sept. 2; the 'Medical Times and Gazette,' Sept. 2; the 'Lancet,' Sept. 2; the 'Medical Press and Circular,' Sept. 1; 'Nature,' Sept. 7; the 'Chemical News,' Sept. 2; 'Gardeners' Chronicle,' Sept. 2; the 'Journal of the Society of Arts,' Sept. 2; the 'Grocer,' Sept. 2; 'Produce Markets Review,' Sept. 2; the 'English Mechanic,' Sept. 1; the 'Pharmacist' for August; the 'American Chemist' for August; the 'Canadian Pharmaceutical Journal' for August; the 'Practitioner' for September; the 'Food Journal' for September; the 'British Journal of Dental Science' for September.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Council of the North British Branch of the Pharmaceutical Society.

Sir,—The head and front of the offence committed, according to Mr. Fairlie's opinion, by the members of the Pharmaceutical Society residing in Edinburgh, has been to call the local committee by the name which it has so long enjoyed. He pleads not only that it is a misnomer, but one likely to mislead. Giving your correspondent more credit for apprehension than it appears he deserves, I wrote a reply to his first communication, in which I pointed out the origin of the name, stating that the "high-sounding title" had been used unchallenged for nineteen years. Mr. Fairlie is still apparently resting on thorns and feels uncomfortable regarding the matter, and with the desire of giving him, if possible, some relief, I will endeavour to make our position in Edinburgh, past and present, plainer still, premising, that he had better again peruse my first reply.

As already explained, a distinct clause in the Act of 1852 appoints an examining body to sit in London and in Edinburgh. At the time the Bill was passed it was felt that there ought to be two centres, one in London and one in Edinburgh, for the operation of the affairs of the Society; and had this not been conceded, the name of "Great Britain" could not have been employed, as Scotland would have rebelled. It is true that powers were also taken to make the examining boards peripatetic, if such was felt to be a necessity, and this power, although never acted upon, still exists. This, however, is widely different from appointing and constituting other boards throughout the country, with all the requisite machinery for conducting the examinations as they ought to be.*

In connection with the existence, then, of the Board in Edinburgh, it became a necessity that a committee should be appointed to look after various matters in connection with the existence of such a Board. A museum required to be founded and a library commenced, in order that certain facilities should be given to young men coming to Edinburgh to pass their examinations, and at the same time scientific meetings were established, at which papers were read and the operations of the Society conducted. These gentlemen formed and still form the Council in Edinburgh. The name, as has already been explained, was given by Jacob Bell, and the funds requisite supplied by the parent Society. A glance at the 'Annals of Pharmacy' since 1852 will tell whether the Council here have since their formation done their duty. Throughout bygone years billets were freely sent both to large cities and country towns, and the tale can be told by many of how seldom came a response, while the presence of friends from a distance at any of our meetings, annual or scientific, always gave much pleasure.

From what I have said, Mr. Fairlie will now, I trust, be able to draw the distinction between the recognized London Council of the Society and the local position of that of the North British Branch. We have neither claim nor power to issue voting-papers for our Council in Edinburgh. All mem-

* The clause referred to by our correspondent (15 & 16 Vict. c. lvi. sect. 9) is as follows:—"And to enable the said Society to provide for the examination in *Scotland* of such students, apprentices, or assistants in *Scotland* as may desire to be examined there, it shall be lawful for the Council of the Society, and they are hereby required, to appoint such fit and proper persons in *Scotland,* to meet in *Edinburgh* or *Glasgow,* or such other place or places as the Council may think desirable, and to conduct there all such examinations as are provided for and contemplated by this Act, with such and the like powers and authorities in respect thereof as are herein conferred, and to grant to the persons to be so examined such and the like certificates as are hereinbefore specified and referred to, or to refuse the same; and all the provisions of this Act shall be equally applicable to the examiners, examinations, and parties examined in *Scotland* as to the examiners, examinations, and parties examined in *England.*"—Ed. Pharm. Journ.

bers, whether in England or Scotland, have the power of voting for the legally-recognized members of London Council, whether they reside on the one side of the Tweed or the other; but there is not and cannot be a second or antagonistic Council in Edinburgh or anywhere else; and if Scotch members generally were entitled thus to vote for the N. B. Branch Council, clearly our English friends would have the same right and privilege. But our constitution is purely local, and our doings and actings must stand for what they are worth. Courtesy and a desire to cultivate good feeling, have induced us to try and get our friends in the country to co-operate with us, but hitherto, I regret to say, with little success.

The attempt made by your correspondent of paraphrasing the proceedings and actions of the Society in Edinburgh, may be considered by Mr. Fairlie as clever, but to my mind it is as ungenerous as it is unjust, while in some respects his statements are at variance with truth. When Mr. Fairlie is able to take museum, library, money grant, honour, and all from us, then Macaulay's prediction will be near its fulfilment, only changing the site and seat of the savage from London to Edinburgh; while, to extend the simile, Arthur's Seat may be expected to be seen as an ornament in front of the Glasgow Royal Exchange. As for the hundred and odd pounds so lavishly expended annually for so many years in Edinburgh, I am constrained to say it only exists in Mr. Fairlie's imagination, and I would recommend him to examine bygone accounts, and wait the issue of the destination of the last grant made by the Society to its branch in Edinburgh, before he indulges in such a hasty and wild statement. It may, however, cause some surprise for Mr. Fairlie to know, that a strong feeling exists in the minds of many, that as in Edinburgh there has really existed, and still continues to show vitality, a part of such a powerful Society as the Pharmaceutical, there ought to be an establishment more worthy the position and name of the North British Branch, and that possibly such feelings may yet find an outlet in some practical form.

With regard to your new and unnamed correspondent who shrouds himself and his habitation under the letters "*M. P. S.*," let me say that when Mr. Bell came to Scotland about the 1852 Bill, he paid a visit to Glasgow, and many still alive can testify to the stirring appeals which he made at a public meeting held there, for sympathy and aid, in the great and good work in which he was engaged. Let a review of what Glasgow has done since then in matters relating to pharmacy tell the amount of his success, and prove whether I was wrong in stating that for many years the Metropolis of the West has been in a state of lethargy. If "*M. P. S.*" knew in detail all the work which "Mr. Mackay and his Edinburgh friends" have had to do in their own locality during the same period, to uphold the character and standing of the Society, he would, I am sure, free them from the charge of having neglected Glasgow or any other town in Scotland. The fact is there ought to be neither recrimination nor jealousy. We are all banded together for one common good, and I can truly say it causes me personally very much regret, when attacks such as the present are made, for I have yet to learn to what extent Mr. Fairlie or his friends in Glasgow are injured or aggrieved, by gentlemen acting for the Society of which they form a part, under a distinctive name, but not interfering in any way, with the proceedings of members of the same Society, in any part of Great Britain. For I assert that the Local Council here, under a name which they have now used for about twenty years, are fully entitled to meet, deliberate and decide on any matter connected with the Society; and having done so, to send up unchallenged to the Council in London such an expression of their opinion; and this being a free country, it is equally open to the committee of any other town to do the same thing.

One word more to "*M. P. S.*" To carry out his original idea of moving the Board further west, in order to save young men their expenses in coming to Edinburgh, he must apply the same argument to all parts of the country, England, Scotland and Wales, and thus establish Boards, not in the west only, but throughout the length and breadth of the east, west, north and south.

I trust our future conduct in Edinburgh will so commend itself to Mr. Fairlie, that he will be prevented from coming, torch in hand, with such fiery intentions as that of setting "the heather on fire." It is true we cannot draw supplies of the cool element from the grand natural reservoir, Loch Katrine, but he may rest assured he will find plenty willing and able hands to assist in preventing the utter ruin of our Branch here, by such a conflagration as he seems to threaten in the closing portion of his letter.

Streathearn House, Crieff, JOHN MACKAY.
4th Sept. 1871.

Sir,—The letter of Mr. Fairlie, in last week's Journal, contains statements as to the conduct and motives of our Edinburgh brethren so directly at variance with my experience, that I feel bound to protest against their being received as correct.

During a long acquaintance with Edinburgh pharmacists, dating from 1853, I have never seen any evidence of the jealousy attributed to them by Mr. Fairlie, but have always found them earnestly desirous that our city should take a place in pharmacy in accordance with its rank and importance in the State, perfectly willing that examinations should be held here if necessary, and ready to aid in anything that might further our progress.

No doubt the Council of the North British Branch is elected by Edinburgh members, but the fact that three of its number belong to Glasgow shows that these elections are not influenced by a spirit of exclusiveness.

In addition, Mr. John Mackay repeatedly urged us to endeavour to send a representative to the London Council, and when Mr. Frazer, of our city, consented to be a candidate for the office, his nomination was at once welcomed in Edinburgh, and every effort made to secure his election.

Mr. Fairlie rightly says, that we have received nothing but kindness at the hands of our Edinburgh brethren, and I regret extremely that he should have allowed himself to publish such charges against a body of men of whom he can comparatively know so little.

ALEXANDER KINNINMONT.
69, *South Portland St., Glasgow, September 6th,* 1871.

POISON REGULATIONS.

Sir,—Mr. Schweitzer, of Brighton, in his letter of the 28th ult., assumes that all who support Government interference in the internal arrangements of the drug shops of this country, act upon the much talked of "regulations" in the storing of poisons in their establishments; and that all who object to Government interference in the matter do so because they are unwilling to act on such regulations in the conducting of their business. Mr. Schweitzer further assumes that the opposition to Government interference is confined to the pharmacists of the "back streets of London and other towns." When Mr. S. has proved these theories of his to be also facts, it will be time enough to discuss the arguments founded on them.

Glasgow, September 2nd, 1871. FRAZER AND GREEN.

Sir,—Last week Mr. Schweitzer, in the opening sentence of his letter, stated that the Brighton poisoning case was the immediate cause of its appearance, though, as he wisely makes no further reference to it, we have, I think, the right to claim his assistance in tracing the connection between cause and effect. I say *wisely*, because the Brighton case proves, if it proves anything, the small value of the legal safeguards of which he is so strong an advocate. On the evidence of good taste and good temper contained in his reference to "back streets," I need make no remark,—such insinuations can only harm those who make use of them, and are best left unanswered; but why should Mr. Schweitzer attach so extravagant a value to the opinions of the gentlemen who represent the leading houses he mentions? That, individually, the views of many of them are entitled to great respect I should be the last to deny, but that respect is in no way increased by the accidental circumstance, that they have the right to hide their identity under the signatures of historic firms; on the contrary, I think it may be fairly argued that this is a question on which their views are entitled to less weight than on many others connected with the trade. Is it not a fact that they carry on business under conditions, differing so materially from those of smaller concerns, especially in poor neighbourhoods, as to afford them no experience on which to form a sound estimate of the difficulties and vexations which beset their less fortunate brethren? As to the remainder of the letter, it is simply irrelevant. How often must we remind our opponents that it is not the sale but the storing of poisons that is under discussion? Is it not strong evidence of the weakness of their case, that they so persistently endeavour to confuse two distinct questions one of which has already been settled by the Legislature?

Far be it from me to suppose that I can influence Mr. Schweitzer. Unlike him, however, I have no objection to argue with those "who do not wish" to be convinced, but only with those who refuse to be, and such letters as his and that of Mr. Balkwill, in a recent number of the Journal, justify us in classing the writers among the latter, and in supposing that it would require something much stronger than reason to make an impression on their prejudices.

CHARLES EVE.

Hampstead, September 4th, 1871.

Sir,—I do not think Mr. Schweitzer's letter and the estimate he forms of his contemporaries in general, ought to pass unnoticed. His inequitable partiality nearly equals that of Squire Western, in Fielding's novel, who wished the whole human race might go to perdition rather than his Sophy should suffer injury to her little finger. Why should the names of those dead people, Bell, Dinneford, Godfrey and Cooke, etc., or their living representatives, or even the managers of the establishments bearing such names, "carry more weight than all the chemists of the back streets of London and other towns taken together"? And, in point of fact, one of those eminent persons, if it were possible to recall him from Elysium and consistency remained among men, would assuredly never "sign any petition in favour of legislative interference."

If the appeal to authority were conclusive, I consider the opinion of Mr. Schacht, who is capable of taking a clear and temperate view of the situations, and of conveying his thoughts to the public in good and forcible language, should avail more than the appeal to a multitude of abstractions. We hold the great metropolitan houses in due respect, but may be allowed to believe there are fifty shops in London where dispensing is quite as well done; and that, too, under the vigilant supervision of a principal whose faculties are quickened by a sense of personal interest and individual responsibility. The same may be affirmed of many a country business; no doubt of Mr. Schweitzer's among the number. A druggist always ought to know, and generally does know, how to order his own affairs better than any extraneous person can instruct him. For my own part, as an Englishman, I claim, or at least desire to retain, the power of conducting my business in the manner which I believe most beneficial to the public interest and to my own. Those who are enamoured of despotism and eager for restraint, are entitled to enjoy their strange opinion. But there is an assumption of superiority in their tone which is unpleasant to the other members of the trade. "Liberavi animam meam."

Truro, September 4th, 1871. S. FEAVER.

Sir,—Like many others I also am quite tired of reading discussions on poison regulations, and would not write a line on the subject but that I think a correspondent last week made some grave mistakes, either from want of experience in country life or from prejudice. I will venture to say that the names of firms like Bell, Dinneford, Godfrey and Cooke, Hanbury, Savory, etc. are not worth more than those of all the chemists in the back streets of London; moreover, in my opinion, they are worth absolutely nothing in comparison with numbers of chemists both in London and the country. Are some half-dozen first-class firms in London competent persons to hold the leading-strings of the country on such a subject as the keeping and dispensing of poisons?

How would they manage if their bread depended not on a high-class trade where 1*s.* may be charged for a single pill, but on one in which they had to supply a number of agriculturists with corrosive sublimate, arsenic, etc.? There are many such businesses in the country, and in most of them dispensing, etc. is, nevertheless, carried out as strictly and correctly as in the first establishments in London. Since we, as a body, cannot agree on the subject, I think it best we should be silent, and agree to differ for the future; let each tub stand on its own bottom; let those that wish for law make one of their own, and those that think differently continue as they think best.

A WEST COUNTRYMAN.

[*** We have inserted these letters—as we did that of Mr. Schweitzer—reluctantly, and simply in the desire to afford to all a fair opportunity of expressing their opinions, and defending themselves. But it is evident that there is no longer any need for continuing this course, and that it might rather be prejudicial than otherwise. We therefore decline to publish any more letters on the subject until such time as it may have assumed such new aspect as may demand further notice. Meanwhile, we commend to our readers such a careful consideration of all that has been written and done in regard to the disputed subject of poison regulations, as may enable them to contribute towards a removal of the difficulties that have distracted British pharmacists during the past few months.—ED. PHARM. JOURN.]

J. David, G. Brownen, "Sempervirens" and *J. S. H.*—We have received the enclosures. They shall be attended to at the termination of the vacation.

"*Ferrum.*"—The iron may be used again, if necessary.

M. M. B.—You will find the names of some firms where you might obtain what you require printed at Vol. I. p. 480, but we cannot undertake to recommend any particular house. You should consult a directory.

"*Theta.*"—Several formulæ for hair dyes have already been given in this Journal. Further information might be obtained by communicating with the Editor of the *Hairdressers' Chronicle.*

G. Brown.—The last edition with which we are acquainted was published in 1866, by Asselin, Place de l'Ecole de Médecine, Paris, price 15, 16, or 17 francs, according to the binding. It might be obtained direct, or through any foreign bookseller.

"*A Country Member*" writes, in reference to the discussion on the merits of Extractum Carnis in last week's Journal, to mention as a somewhat noticeable fact that his dog will not touch food in which Liebig's Extract has been mixed, but will eat with the usual relish the same food containing gravy made in the ordinary way.

A. P. S. (Wolverhampton).—If you had added the spirituous preparations last, you would not have experienced the difficulty referred.

Charles J. Bell (Wellingborough).—(1.) The proper way is to distil the oil with water, and to apply the usual tests to the distillate. (2.) Yes, providing a registered chemist and druggist were engaged.

R. and Co.—It would be necessary for the seller to put on a 3*d.* stamp, or to have a sweet wine licence.

J. Bingley.—The hydrochlorate of morphia may be kept in solution by using a larger proportion of solvent. It requires twenty parts of water for solution. See a paper on the subject by Mr. Martindale, PHARM. JOURN., 2nd Series, Vol. XI. p. 480.

B. R.—The quantity of liquor potassæ is insufficient to form an emulsion. Mucilage, or yolk of egg, would have answered the purpose better, though, of course, it would have been improper to have used them in the case referred to.

R. B. S. (Salford).—The Pharmacy Acts are, 31 & 32 Vict. cap. 21, and 32 & 33 Vict. cap. 117. These and other Acts referring to the qualifications of chemists and druggists and to the sale of drugs, may be found in the Calendar of the Pharmaceutical Society of Great Britain, which can be obtained from the Registrar, price 1*s.* 3*d.*

Philip Miller (West Derby).—We are at a loss to account for your experience.

ERRATUM.—*The Pharmacy Bill.*—Mr. Schweitzer writes to say that in his letter of last week, the sentence:—"Names like Bell, Corbyn, Dinneford, Godfrey and Cook, Hanbury, *Savage*," etc., should be read:—"Names like Bell, Corbyn, Dinneford, Godfrey and Cook, Hanbury, *Savory*, etc., carry more weight than all the chemists of the back streets of London and other towns taken together."

COMMUNICATIONS, LETTERS, etc., have been received from Mr. C. H. Southwell, Mr. G. Burrell, Mr. J. R. Jackson, Mr. W. Gill, Mr. G. Cocking, Messrs. J. Sanger and Sons, C. M., N. O. P., R. B. S., "Philos," "Fair Profit," "Chemicus" (Sheffield). "Chemicus" (Redditch), "Amara" and "Anonymous" are referred to the rule as to anonymous correspondence.

CHEMICAL AND PHYSIOLOGICAL RESEARCHES UPON THE NATURE OF THE PURGATIVE PRINCIPLES OF ALEXANDRIAN SENNA.

BY MM. E. BOURGOIN AND E. BOUCHUT.

Senna has been successively analysed by Bouillon-Lagrange and Braconnot, then by Lassaigne and Feneulle, and more recently by Ludwig, Batka, Kubly and Dragendorff.

Bouillon-Lagrange prepared an aqueous distillate, which had a nauseous odour and was slightly purgative, but he failed to isolate any definite principle. The same may be said of Braconnot, who attributed the properties of senna to a bitter substance of a complex nature, obtained from the watery extract.

The results obtained by Lassaigne and Feneulle in 1821 are most important. Those chemists prepared a substance to which they gave the name of cathartine, and to which they attributed the special properties of the senna. It may be remarked in passing that the name cathartine ought not to be retained in science, for the product which it denotes is not a definite substance.

According to Dragendorff and Kubly, senna owes its properties to a particular acid—cathartic acid; but these writers, like the preceding, gave no precise details by which their assertion could be substantiated.

In consequence of these contradictory results, it was thought by the authors that it would be interesting to make a fresh investigation of the subject, particularly to determine the nature of the body or bodies to which the purgative properties of senna are to be attributed.

After some preliminary experiments which it is unnecessary to report, the following was the method adopted in this delicate research.

One kilogram of picked Alexandrian senna was treated with ten times its weight of boiling distilled water; after standing twenty-four hours it was expressed, and the resulting liquor filtered and evaporated by a water-bath to two litres. Then its own volume of alcohol was added, which caused the formation of an abundant precipitate that was separated. The liquid, cleared from this principle, was reduced by evaporation to the weight of one kilogram. From this product might be prepared, on the one hand, the cathartine of Lassaigne and Feneulle, on the other, the cathartic acid of Dragendorff and Kubly.

In this memoir will be examined in the following order—(1) the mucilaginous matter; (2) the liquid extract; (3) the cathartine of Lassaigne and Feneulle: (4) a new substance, ? catharto-mannite; (5) the cathartic acid; (6) the chrysophanic acid of the senna.

1. *Mucilaginous Matter.*

Mucilaginous matter exists in large quantity in senna, to the extent of about one-tenth of its weight. It is separated immediately by adding to a concentrated infusion an equal volume of 45 per cent. alcohol. Left to stand, it collects upon the surface of the liquid, whence it may easily be taken, and should then be washed several times with alcohol to free it from the liquid extract with which it is impregnated. When afterwards dissolved in its own weight of water, a solution is obtained that is slightly clouded and sluggish, with a mucilaginous flavour, not at all bitter. This is the solution with which the experiments were made, and which has yielded the following results.

Physiological Effects.—We have administered the mucilaginous matter of senna to fifteen children of from five to thirteen years of age, in doses of five, six, ten and fifteen grams.

Eight times, that is to say in more than half the cases, it had no purgative effect; two of these children had griping pains, but beyond that no appreciable disturbance was noticed either of feverishness or loss of appetite.

Upon the other seven it had a slight purgative effect, characterized in three by a single muddy evacuation, and by two to four yellowish liquid evacuations in the others; but in neither case was there any fever.

In order to compare the action of this mucilaginous matter derived from senna with the liquid extract described further on, the following experiments were made.

To a child twelve years of age who had taken successively six grams of mucilaginous matter, and the next day ten grams, without any purgative effect, was given on the third day ten grams of liquid extract, which caused two liquid painless evacuations.

To a child fourteen years of age, to whom fifteen grams of the mucilaginous matter had been given without producing any sensible effect, was administered on the following day, 15 grams of the liquid extract, which caused two liquid evacuations with griping pains.

From this it appears that the mucilaginous matter of senna, when in a pure state, is not purgative in doses up to 15 grams, which would be equivalent to 150 grams of the leaves, and that without exceeding such dose, abundant evacuations are not produced by it. It is, however, easily explained how it is that the mucilaginous matter of senna sometimes exercises a slightly purgative action. The product of Dragendorff and Kubly, which, as will be seen, is purgative, is insoluble in concentrated alcohol; it is probable, therefore, that a small quantity of that substance is contained in the mucilaginous matter from which it is difficult entirely to eliminate it.

As a result of these experiments it appears that the mucilaginous matter ought not to be regarded as one of the purgative principles of senna.

2. *The Liquid Extract.*

The infusion of senna, deprived by alcohol of the mucilaginous matter, was evaporated in a water-bath at a gentle heat, so as to drive off the greater part of the alcohol, and to obtain finally a quantity of liquid equal in weight to the leaves originally used. The liquid so obtained is of a dark brownish-yellow colour, and possesses a bitter, slightly nauseous flavour. It gives no precipitate with water or proof-spirit, but with absolute alcohol it yields an abundant precipitate, which will be referred to further on.

Physiological Effects.—The effects of this liquid, which represent, properly speaking, the infusion of senna, are, as might be expected, very marked upon the secretions and the contraction of the intestines. This has already been noticed in comparing in the same patient the purgtive a action of this preparation with that of the preceding. But without making comparisons, the energetic action of the liquid extract shows itself in an absolute manner by the extent of the effects produced. Thus the liquid extract was administered to thirty-one children, of ages varying from five to fifteen years, and only three patients were met with upon whom it did not have a purgative effect.

It was administered in doses of from 6 to 30 grams. In the three cases in which it had no effect, only 10, 15 and 20 grams had been administered.

In two cases there was but one motion; in seven cases, two motions; in two cases, three; in six cases, four; in five cases, five; in three cases, six; and in three cases, seven. These evacuations were yellowish, liquid, more or less abundant, and after the purgation there was neither uneasiness nor fever.

Some of the patients suffered from nausea, some from griping, and some vomited. One of the patients upon whom 20 grams of the liquid extract had no purgative effect, vomited, which doubtless explains the absence of purging. Three others had nausea, and fourteen altogether had colic pains, which shows the convulsive intestinal action of the preparation employed.

3. *Cathartine.*

In the preparation of this product, Lassaigne and Feneulle adopted a rather complicated method. The senna was first exhausted with ether, then the residue was treated by water and partially distilled. The decoction remaining in the retort, expressed and filtered, was afterwards treated with neutral acetate of lead, which gave a plentiful precipitate that was rejected. The liquor, deprived of any excess of the reagent by a current of sulphuretted hydrogen, was taken up again by rectified spirit, and the alcoholic solution evaporated to the consistence of extract; this was afterwards dissolved in alcohol acidulated with sulphuric acid, then filtered to separate the insoluble sulphate of potash that was formed. After precipitating the sulphuric acid by acetate of lead, separating this last reagent by sulphuretted hydrogen, filtering anew and evaporating to dryness, cathartine was obtained, a substance which, according to those authors, stands in the same relation to senna as emetine to ipecacuanha.

The treatment by ether, and the distillation, are two useless operations. A product exactly similar may be prepared much more simply in the following manner:—Digest one kilogram of senna in two different quantities of from eight to ten times its weight of distilled water; raise it to the boiling-point and then leave it to cool; after twenty-four hours press strongly and filter. Mix the two liquors and evaporate to one litre, which treat by its volume of spirit to separate the mucilaginous matter. Evaporate the spirit by a water-bath, and add to the residue neutral acetate of lead, which will give rise to a plentiful precipitate that is to be rejected. Separate the excess of lead by sulphuretted hydrogen, then filter, evaporate to a syrupy consistence, treat with rectified spirit, filter, and add carefully very dilute sulphuric acid as long as there is any precipitate; filter again, and evaporate by a water-bath.

The substance so obtained is of a reddish-yellow colour, with a bitter nauseous taste, recalling that of senna. It is hygrometric, soluble in water and in spirit, but not completely insoluble in ether, as indicated by Lassaigne and Feneulle. An aqueous solution gives an abundant precipitate with subacetate of lead, and becomes darker under the influence of alkalis.

Physiological Effects.—In order not to employ doses capable of injuring the patients, at first 20 centigrams were given, then 1 gram to children from six to thirteen years old. No effect following, the dose was raised to from 5 to 10 grams, according to the age of the children.

In seven cases where cathartine was administered in 5 gram doses, there was but one with a negative result. In the other six there were from one to four liquid evacuations, twice accompanied by nausea and three times by griping pains, but in none of them was there any vomiting, uneasiness or fever.

Three times the cathartine was given to the elder children in doses of 10 grammes. The purgative effect was not very strong, there being but one, two and four motions, without nausea or vomiting, and in only one case with pain.

If it be remembered that senna only yields about one-thirtieth of its weight of cathartine, it will be seen that this preparation evidently has not the strength of the liquid extract, and consequently cannot pretend to represent by itself the purgative principle of senna.

4. *A New Substance* (*Catharto-mannite ?*).

This substance, which is very soluble in water, insoluble in concentrated alcohol and in ether, is obtained as a secondary product in the preparation of cathartine. The process is as follows:—After having separated the mucilaginous matter from the infusion of senna, the solution is concentrated, and acetate of lead added to it; the liquid is filtered, deprived of excess of lead by sulphuretted hydrogen, and evaporated to a syrupy consistence, then treated with concentrated alcohol: the insoluble residue contains the substance in question. This is dissolved in a little water and precipitated afresh by alcohol. After repeating this treatment two or three times, the product did not appear sufficiently pure for chemical analysis; but, nevertheless, it was thought advisable to submit it to a few clinical experiments, in order to determine its therapeutic value. It was dissolved in sufficient water to give a ten per cent. solution.

Physiological Effects.—Doses of one gram were administered to five children without producing any effect. There were neither nausea, gripings nor evacuations. Two days afterwards the same children each took 2 grams of this product; the result was equally negative. The same want of success was experienced the following day with 5 gram doses, no uneasiness being produced. These five children not only were not purged, but appeared rather to be constipated under the influence of this preparation. In consequence of this result 15 grams of the liquid extract was given to each of these children, which produced in every case plentiful evacuations.

5. *Cathartic Acid.*

This acid was prepared in the following manner: An infusion, made with one kilogram of Alexandrian senna, was concentrated so as to obtain one litre of product, to which was added its volume of 75 per cent. alcohol. The precipitated mucilaginous matter was separated by filtration; then the liquid was evaporated to a syrupy consistence and precipitated by absolute alcohol. This new treatment yields a blackish body, which was dissolved in water and precipitated by dilute hydrochloric acid. The resulting product, which was the impure cathartic acid of Dragendorff and Kubly, was dissolved with heat in proof spirit. Finally, the solution so obtained having been partially evaporated, and exactly saturated by a weak solution of potash, the cathartic acid was again set free by hydrochloric acid. One kilogram of senna yields six to seven grams of cathartic acid so purified.

This acid is insoluble in water. In order to administer it in an aqueous solution, and in a state analogous to that in which it appears to exist in the plant, that is to say as a salt, it was exactly saturated with a weak solution of potash, so as to obtain a one per cent. solution; each gram of this solution consequently answering to a centigram of cathartic acid.

Physiological Effects.—The solution of cathartic acid so prepared, was given to children of from six to fifteen years of age, in doses of from 15 to 30 grams. Of seven patients who had taken the smaller dose, in four cases it was without effect; of the other three cases, in one there was one stool, in one three, and in one four, without nausea or vomiting, but with some griping. In two other cases where 30 centigram doses were given, but one single evacuation resulted, without nausea, vomiting or pain.

It appears, therefore, that the cathartic acid does not by itself represent the whole of the purgative action of senna. Supposing that senna contained one-hundredth part of its weight of this acid, which is certainly the maximum, 30 centigrams would correspond to 30 grams of the leaves, and, consequently, to 30 grams of the liquid extract. It has been shown that the latter, with this dose, exercises a much more energetic action.

6. *Crysophanic Acid.*

It has been remarked that the cathartine of Lassaigne and Feneulle was not a definite principle, but should be considered to be a mixture of many substances, of which one at least is purgative. Without seeking to define exactly the nature of this mixture, which one of the authors intends to do ulteriorly, it appeared interesting to ascertain to which portion of the product the purgative properties of cathartine might be attributed. This was done in the following manner:—

The cathartine was briskly agitated with ether, deprived of alcohol, and this treatment was repeated many times, as the exhaustion is difficult. The ethereal solution, of a strong yellow colour, was evaporated in a water-bath. The residue having been taken up by absolute alcohol, the filtered solution was evaporated to the consistence of an extract. A product, containing two different principles, was thus obtained, one of them a colouring matter, and the other possessing all the properties of the acid still indefinitely described under the name of chrysophanic acid. This substance is nearly insoluble in water, strongly soluble, on the contrary, in alcohol and in ether; its solution, which is yellowish, and reddens tournesol paper, acquires a beautiful red colour under the influence of alkalis. The salts so formed are very soluble in water, which allows of the separation of the organic acid by means of acetic acid. This product was made up into pills, each containing 10 centigrams.

With a dose of 60 centigrams there was no effect. With a dose of 1 gram a decided purgative effect was obtained.

However, it is willingly acknowledged that the action of crysophanic acid would not be precisely the same as in these experiments, since in these it was not used in a state of purity. It is proposed in another investigation to operate with crysophanic acid, obtained from rhubarb, and not from senna, this last appearing to contain but a very small quantity, which explains why the presence of the acid in it has been doubted by some experimenters.

From the preceding result, it would appear that the purgative principle contained in cathartine should be present in the portion insoluble in ether. This, in fact, is found to be the case. Deprived by ether of all matter soluble in that vehicle, cathartine has given the following results. Upon a patient fourteen years old, 2 grams in a draught produced uneasiness, loss of appetite, nausea, some griping, and five evacuations. In a second case, upon a young girl of twelve years and a boy of the same age, the same dose gave rise to exactly similar symptoms.

Conclusions.

It results from the facts mentioned in this memoir that senna cannot be classed with the plants that possess but a single purgative principle. It is evident that to this circumstance must be attributed the difficulties that have hitherto been experienced in the analysis of this substance, and the uncertainty which exists still in science concerning the nature of its active principle.

It has been clearly shown that no single one of the constituent principles of the plant, taken by itself, can pretend to represent the whole of its general properties. In other words, besides chrysophanic acid, which only exists in small quantity, senna contains at least two other purgative principles: one represented by cathartic acid; the other contained in the preparation of Lassaigne and Feneulle improperly called cathartine. This conclusion is evident, as the authors have satisfied themselves, that cathartine contains no trace of cathartic acid.

As a general result of this inquiry, it appears that the best preparation of senna is the infusion, with or without the mucilaginous matter,—such as that described in this memoir under the name of liquid extract, for example,—since only such a preparation contains all the purgative principles of the plant.—*Journ. Pharm. Chim.* (4) xii. 305.

OPIUM PRODUCTION IN EUROPE.

BY DR. C. O. HARZ.

Some fifty years ago experiments to produce opium in Europe were made which were so successful as to strongly recommend to the farmer the cultivation of poppy.

In Germany and Austria the idea did not find much favour, and was soon forgotten, while in France it was taken up and carried out on a large scale. The cultivation of poppy increased year after year, and it now occupies about 50,000 acres, of the value of four and a half million francs, yielding two million francs of opium a year. More recently Mr.

Karsten has revived the interest in the question in Germany, and in several parts of the country trials have been made with most favourable results.

Experiments made at the acclimatization fields, near Berlin, proved that the giant, the blue and the white poppy were best suited for the production of seed on that soil; these three varieties were therefore planted on a well-manured sandy soil, and the opium obtained therefrom showed all the external qualities of a good Smyrna sample, analysed.

	Soluble in Water.	Organic Bases.	Of which Morphium.
Giant Poppy .	66·3 per ct.	13·6 per ct.	9·3 per ct.
Blue „	70·1 „	10·7 „	8·0 „
White „	69·6 „	8·0 „	—

The last sample was in too small a quantity to give exact results.

In 1866, several experiments made near Berlin, viz. at Pankow, Charlottenburg and Hermsdorff, yielded opium containing 10 per cent. of morphium.

Karsten sowed the seed in two lines about 6 inches apart, and separated by about 2 feet distance from the next two lines, so as to allow free passage in gathering in the opium; the young plants were kept asunder about 3 to 4 inches.

About eight days after florescence the poppies were cut, and the milk juice, a few minutes afterwards, collected with the finger in a vessel, and at once evaporated at a gentle heat; the result was of superior quality, containing 66 per cent. soluble in water, and 10 per cent. of morphia An instrument called the scarificator, for making the incisions, was not approved of, but the most suitable instrument was an ordinary garden-knife or penknife, provided with a guard to prevent its making the incisions so deep as to cut through the capsules. This is of great importance, because the cutting through of the poppy-heads is invariably followed by a shrivelling up of the young fruit, so that not only the juice but also the seed is lost.

Mr. Schulze, a schoolmaster at Pankow, commenced in 1867, and he also found it best to collect the fresh juice, instead of allowing it spontaneously to dry on the fruits, giving a much purer quality. Dr. Harz received samples of the opium produced, and found it to contain 10·9 per cent. of morphia; after having been kept for some time in a paper box, it showed the following properties:—It was tough and tolerably hard, greyish-brown, somewhat like German lactucarium, forming a mass of tears of the size of a pea, of waxy surface when cut, with difficulty reduced to a light grey powder. The smell was intense, stronger than that of Smyrna opium, and also resembling lactucarium; the taste exactly like that of best Smyrna.

The tincture made according to the Prussian Pharmacopœia was slightly brown, somewhat like Madeira wine, scarcely one-third so intense in colour as the tincture made from Turkish opium, according to English prescription. Analysis of the sample dried at 100° C. gave, soluble in cold water 49 per cent.; the insoluble consisted chiefly of narcotine, of a resinous mass 7 per cent., and caoutchouc and fat soluble in chloroform 14 per cent.

The aqueous extract, containing 49 per cent. of the opium, and containing besides morphia scarcely 1 per cent. of other bases, was brought nearly to dryness in a water-bath, and extracted with alcohol. There remained 9·4 per cent. of gummy substances and organic salts; the filtrate mixed with water gave, on gradual addition of ammonia, after ten days, 10·9 per cent. crystals of morphia.

The opium was therefore of very good quality, and the separation of morphia was facilitated by the lighter colour of the juice.

In 1868, opium cultivation was commenced at several places in Würtemberg. Mr. Julius Jobst, of Stuttgart, made experiments, which are very valuable, because as the first on a really large scale they established the profitable character of the speculation. Several acres of land were sown with poppy-seed; a fortnight after the fall of the petals the young heads were cut, and the juice collected; this was repeated a second time, but a third incision did not yield enough to pay for the labour. The best time for the incision is the early morning, shortly after sunrise; on hot days, and especially in the middle of the day, only very little juice was produced. The exuded juice, after slight desiccation, was collected in a tin box, the pasty mass was dried in the shade, and wrapped up in poppy-leaves in the shape of small loaves; the manufactured opium formed dark brown cakes, and contained 13 per cent. of morphia.

Mr. Vulpius, pharmacist at Bocksberg, near Heidelberg, produced some opium in 1870, samples of which are now in Dr. Harz's possession for analysis. Dr. P. Sorauer made, at the same time, successful experiments at the Agricultural Experimental Establishment at Dahme, near Berlin; he made the important observation, that the incised capsules yielded more seed than the sound ones, which would increase the profit in a new direction.

The manufacture of olive oil is, in Austria, in a very primitive state, and large sums of money go out of the country to be invested in good salad oil, which if kept at home, and laid out in opium cultivation, would assist in manufacturing a pure poppy oil, exceeding in agreeable taste the olive oil. The incisions must be made in fourteen to eighteen days after the petals have dropped, and, according to Jobst's experience, in early morning. Gastimel, of Cairo, in the *Journal de Pharm. et de Chim.* 1865, draws attention to the fact, that opium obtained from nearly ripe poppies yielded 10 to 12 per cent. of morphia, while another sample, collected directly after florescence, gave a pretty large yield, but contained only 3 to 4 per cent. of the alkaloid. The condition of the soil is of course of importance, although opinions differ on this point; Gastimel finds a well-manured soil to yield opium rich in morphia, while Figari-Bey comes to the reverse conclusion, and the last view is strengthened by Dr. O'Shaughnessy, who observed in East India that opium grown on manured soil contained less morphia than that from an unmanured soil. Certain it is, that newly manured soil acts unfavourably upon the poppy-seed.

In order fully to develope the opium cultivation at home, it will be necessary to settle the following questions, viz.:—

1. Which variety of poppy produces most seed and the best opium, richest in morphia?

2. What influences does the quality of the soil (presence of chalk, manure, etc.) exercise upon the formation of the two products?

3. Which is the most favourable time for cutting the poppy-heads?

4. Does the yield of seed increase with the incision?—*Zeitsch. oestr. Apotheker-Vereines, July*, 1871.

FORMULARY OF ELIXIRS AND PREPARATIONS OF THE NEWARK PHARMACEUTICAL ASSOCIATION.

A short time since we recorded the fact* that the Newark (New Jersey) Pharmaceutical Association had issued a formulary of elixirs and unofficinal preparations, by which they proposed to dispense all such compounds unless specially directed otherwise by the prescriber. The following reprint of this formulary is taken from the *Chicago Pharmacist.*

Wine of Beef and Iron.—

℞ Extracti Carnis (Liebig's) 1 oz.
Ferri Citrat. 96 grs.
Vini Xerici 16 oz.
Syrupi 2 oz.
Pimentæ (contus.) ½ dr.
Aquæ q. s. ft. 24 oz.

Dissolve the extract of beef in 4 oz. of water and add the allspice; after standing ten hours add the wine and syrup, then the citrate of iron, previously dissolved in 2 oz. water: filter.

Each fluid ounce contains: fresh beef, 1 oz.; citrate of iron, 4 grains. Dose—one tablespoonful.

Nutritive Wine. Liebig's Extract of Beef and Wine.—
Prepared same as above, omitting the citrate of iron.

Elixir Calisaya.—

℞ Cort. Cinchonæ flav. ½ oz.
,, ,, (Calisaya) ½ oz.
,, Aurantii ½ oz.
Sem. Coriand. 2 dr.
Cocci Cacti 1 dr.
Spts. Vini Deod. 12 oz.
Aquæ 10 oz.
Glycerinæ 5 oz.
Syrupi 5 oz.

Reduce the barks, etc., to a moderately fine powder, and pack firmly in a percolator; mix the deodorized spirits, water, glycerine and syrup, adding enough water to make two pints of percolate, to which add 20 grains of powdered tartaric acid, and after standing twenty-four hours, filter.

Each fluid ounce contains: 16 grains cinchona bark.

Elixir Pyrophosph. Iron and Quinine.—

℞ Ferri Pyrophosph. 160 grs.
Quiniæ Sulph. 10 grs.
Spts. Vini Deod. 2½ oz.
Syrupi 3 oz.
Aquæ 9½ oz.
,, Flor. Aurantii 5 oz.
Acid. Sulph. dil. q. s.

Dissolve the pyrophosphate of iron in the water and add the syrup; then dissolve the quinine in the orange-flower water, with as little diluted sulphuric acid as possible, and gradually mix them: filter.

Each fluid ounce contains: pyrophosph. iron, 8 grains; sulph. quinine, ½ grain.

Elixir Quinine, Iron and Bismuth.—

℞ Elixir Ferri Pyrophosph. et Quiniæ 16 oz.
Bismuth, Citra-Ammon. 128 grs.
Dissolve.

Each fluid ounce contains: 8 grains pyrophosph. iron; 8 grains citrate of bismuth; ½ grain quinine.

---

* Vol. I. p. 1034.

Elixir Pyrophosph. Iron, Quinine and Strychnine.—

℞ Elixir Ferri Pyrophosph. et Quiniæ 16 oz.
Strychniæ 1 gr.
Dissolve.

Each fluid ounce contains: pyrophosph. iron, 8 grains; quinine, ½ grain; strychnia, 1-16th grain.

Wine of Pepsin.—

℞ Pepsin (Hawley's) 160 grs.
Vini Xerici 16 oz.
Acid. Mur. Dil. 1 dr.

Triturate the pepsin with 4 oz. of wine mixed with acid. Pour this upon a filter, and pass the balance of the wine through it.

Each fluid ounce contains: Hawley's pepsin, 10 grs.

Elixir Aromatic.—

℞ Cort. Aurantii 4 drs.
Sem. Coriand. 2 drs.
,, Angelicæ 2½ drs.
Cocci Cacti 1 dr.
Spts. Vini Deod. 12 oz.
Aquæ 10 oz.
Glycerinæ 5 oz.
Syrupi 5 oz.
Percolate 2 pints.

A pleasant vehicle for administering nauseous remedies.

Elixir Val.-Ammonia.—

℞ Ammoniæ Valerianat. 96 gr.
Fl. Ext. Vanil.,
Tr. Cardam. Comp. āā ½ oz.
,, Xanthoxyl, 2 drs.
Syr. Aurantii Cort. 6 drs.
Aquæ 4 oz.

Dissolve the valerianate of ammonia in the water, and add the other ingredients, previously mixed.

Two grains Val.-Ammon. to each drachm.

Comp. Syrup of Hypophosphites and Iron.—

℞ Hypophos. Sodæ,
,, Calcis,
,, Potassæ āā 256 grs.
,, Ferri 126 grs.
Aquæ 12 oz.
Sacch. Alb. 18 oz.

Dissolve the hypophosphites in the water in a water bath, and filter. Add sufficient water to make up for the evaporation. Add sugar—and apply gentle heat to make syrup—21 oz.

Each fluid ounce contains: hypophosphite of soda, lime and potash, 12 grains each; hypophosph. iron, 6 grains.

Compound Syrup of Hypophosphites.—
Same as above, omitting the iron.

Chemical Food.—

℞ Parrish's formula, omitting cochineal and muriatic acid. See U. S. D.

Each teaspoonful contains 1 grain phosphate of iron, 2½ grains of lime and the other alkaline phosphates.

Elixir Pepsin, Bismuth and Strychnine.—

℞ Pepsin (Hawley's) 256 grs.
Bismuth. Citrat. 64 grs.
Strychniæ 1 gr.
Aq. Flor. Aurantii 6 oz.
Spirit. Vini Deod. 2 oz.
Aquæ 4 oz.
Glycerinæ (pur.) 2 oz.
Syrupi 2 oz.

Triturate the pepsin with the water and glycerine, and filter; dissolve the bismuth in 2 oz. orange-flower water, with a few drops of aqua ammoniæ; dissolve the strychnine with a few drops of acetic acid. Add the bismuth solution to the pepsin, then the balance of the fluids, and finally the solution of strychnia.

Each fluid ounce contains: pepsin, 16 grains; citrate of bismuth, 4 grains; strychnine, 1-16th grain.

Ferrophosph. Elixir Gentian.—

℞ Cort. Aurantii 1 oz.
Sem. Coriand. 1 dr.
Macis 1 dr.
Rad. Gentian. 1 oz.
Spts. Vini Deod. 4 oz.
Aquæ 4 oz.
" Flor. Aurantii 2 oz.
Syrupi 6 oz.
Ferri Pyrophosph. 256 grs.

Reduce the roots, seeds, etc., to a moderately fine powder, pack in a percolator—mix the spirits and waters, and percolate 10 ounces. Dissolve the pyrophosphate of iron, add the syrup and filter.

Each fluid ounce represents: 16 grains pyrophosph. iron; 30 grains gentian.

THE COLLECTION OF MASTIC AT CHIOS.

BY M. J. LÉON SOUBEIRAN.

Mastic flows from the *Pistacia Lentiscus*, a Terebinthaceous tree, growing principally in the south of the Isle of Chios, about Cape Mastic, which takes its name from this resin, and is situated about an hour's journey from the city of Chios. According to the natives it exudes, not only from artificial incisions, but also spontaneously from the branches, where it congeals in drops, which, under the name of *dakra* (tears), are gathered separately, and constitute the most esteemed kind. But the bulk of the resin issues from vertical incisions skilfully made with a knife close together round the whole circumference of the trunk, from the root to the branches. A few hours after this operation, which is done about the middle of June, there issues from the incisions a resinous, transparent, aromatic substance, which soon solidifies. After fifteen or twenty days this resin is collected in little baskets, lined with white paper or clean cotton cloths. Previous to this time the ground underneath the tree is covered so as to prevent the juice, which runs plentifully, from being soiled by the earth. If such contamination does take place, care is taken to cleanse it directly it is collected. The production of resin, which is collected by women and children, lasts about six months, and is valued at about £8 to £10 for a full-grown tree.

The mastic that exudes spontaneously is divided into two kinds,—the *kadisto*, which averages in value 100 Turkish piastres, the oke of 1200 grammes, and the *phliskari*, which has nearly the same value. That which drops from the incisions and is picked up from the ground is the *pectta*, worth 80 piastres the oke; whilst the worst quality, that which is mixed with earth, called *phluda*, is only worth from 40 to 60 piastres.

The annual production is about 2,000,000 drachms, and is attributed, by the natives of Chios, to the intervention of Saint Isidore, martyred in that island in the third century; the drops of blood of that martyr having given birth, they say, to the mastic tree.

In the East mastic is employed to strengthen the gums and to perfume the breath. It is at present little used in medicine, but principally in the arts, in the preparation of varnish.

A turpentine which has enjoyed a great reputation is also obtained at Chios, from the *Pistacia Terebinthus*, by means of more or less deep incisions in the trunks of the larger trees.—*Journal de Pharmacie et de Chimie.*

THE INFLUENCE OF SUNLIGHT ON PETROLEUM OILS.

BY M. GROTOWSKY.

In some recent experiments made by M. Grotowsky, he has shown that when petroleum oils are exposed, under certain conditions, to sunlight, they absorb oxygen from the air, which is converted into ozone, a phenomenon that has already been observed in some other hydrocarbons. No chemical combination takes place between the oil and the ozone, but the latter remains free, and oxidizes strongly any substance with which it comes in contact.

In oils containing ozone the smell is completely modified; they burn with difficulty, and attack rapidly the stoppers of the vessels containing them, especially if the stoppers be of cork. When glass vessels are used, it has been found that the colour of the glass exercises a great influence over the absorption of oxygen. Decolorized oils, exposed in white glass vessels to the action of sunlight, turn yellow, become charged strongly with ozone, and burn with difficulty. This is principally the case with the American petroleums. They should therefore be kept in metallic vessels, or if glass be used, it should be shaded as much as possible from the sun.

ACONITINE.

MM. Gréhant and Duquesnel recently presented to the French Academy of Sciences a memoir on aconitine, which M. Duquesnel has succeeded in extracting from *Aconitum Napellus* in the form of rhombic or hexagonal plates. The alkaloid is the active principle of this plant. In order to obtain it, the author extracted the root of the *Aconitum* by concentrated alcohol, with the addition of 1 per cent. of tartaric acid; the excess of alcohol was then removed by distillation, and the residue diluted with water in order to precipitate the fatty and resinous matters. The aqueous solution of tartrate of aconitine was then treated with an alkaline bicarbonate in order to set the alkaloid at liberty, this latter being scarcely very slightly soluble in water. It dissolves in ether, which, on evaporation, leaves it in the crystalline condition. M. Duquesnel assigns to it the formula $C_{54}H_{40}NO_2$. Aconitine is very slightly soluble in water, very soluble in alcohol, ether, benzine and chloroform. It is not volatile, and commences to decompose about 130° C. Its reaction is feebly alkaline. It combines with acids to form crystallizable salts; the author cites the acetate as presenting abundant crystals. Phosphoric acid, tannine, potassium iodide and iodate, and the double mercury and potassium iodate, produce the ordinary reactions on organic alkaloids. Aconitine is a powerful poison, its physiological action being analogous to that of curari, destroying the motor power of the nerves, but leaving the power of producing reflex actions untouched, at least in small doses.—*Revue Scientifique.*

Maquey.—This plant, more commonly called the hemp aloe, is found in most parts of the Philippine Islands. The natives obtain the fibre from it by cutting the thorns off and scraping the leaves on a block of wood with a shell until the pulpy matter is cleared away; the fibre is then hung up in the sun to dry. Another method is to beat out the leaves with a mallet and steep them in water for five days, the fibre is then easily obtained. This plan is much easier than the first, but the quality of filament produced is somewhat inferior. Very fine textures were at one time made from the fibre of the maquey, but it is now chiefly used by the natives for fishing purposes. The maquey fibre, after being steeped in a mixture of blood and lime, is said to be impervious to water.—*Consul's Report.*

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 16, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

CULTIVATION OF IPECACUANHA IN INDIA.

IT will be in the recollection of many of our readers that we have on several occasions referred to this subject,* and that last February we published an abstract of a lecture delivered by Prof. BALFOUR to the pharmaceutists of Edinburgh, in which he gave an account of what steps had been taken for introducing the cultivation of ipecacuanha in India.

It is scarcely necessary to insist upon the importance of this attempt, should it prove successful, and it is with especial pleasure therefore that we have been enabled through the kindness of Professor BALFOUR to communicate the very hopeful report that has been forwarded from India on the safe arrival of the plants. The following letter from Mr. WALTON (who took charge of the plants) to Professor BALFOUR has been forwarded through Mr. JOHN MACKAY:—

"*Bombay*, 31*st July*, 1871.

"Dear Sir,—According to promise I write to say that your case of ipecacuanha plants has reached Calcutta safely; much of this is due to the admirable packing. I never saw plants so well packed for a long voyage. Dr. King writes to me from Calcutta as follows:—'You will be glad to hear that the plants are in excellent condition. In fact I never saw plants arrive in a better state of health.' These plants will now have all the rainy season as well as the cold, to gather vigour for next hot weather, and I am now more than ever convinced that June or July is (with careful personal superintendence the whole way) the proper time to dispatch cases of plants (of most kinds) to India. We had trying weather too in the Red Sea. The thermometer registered as high as 108° repeatedly. I trust you may succeed with future cases. We ought to have some for trial in the Bombay presidency.

"I am, dear Sir, yours truly,
"(Signed) W. WALTON."

"J. W. BALFOUR, Esq., M.D.
"Professor of Botany, Edinburgh.

It will be seen from this letter that the arrangements, so far as they have gone, have proved satisfactory, and we learn that there are at this moment about 100 plants in the Edinburgh Botanical Garden ready for transmission to India when required. If this attempt be successfully carried through, our Government will have had the satisfaction of having introduced into India two most important pharmaceutical plants, cinchona and ipecacuanha, and as regards the latter, we shall be greatly indebted to Professor BALFOUR for the part he has taken in providing the plants.

* PHARM. JOURN. 3rd series, Vol. I. No. 5, p. 170.

HYDRAULIC TINCTURE PRESSES.

SOME months ago* reference was made to the use of hydraulic presses for tinctures and the advantages of using them were pointed out. We are gratified at finding that in consequence of the attention thus directed to the subject Messrs. HAYWARD TYLER and Co. have been endeavouring to provide a suitable hydraulic press for the use of pharmacists, and we are informed that they will shortly introduce it. We are also promised a description of this press, which we shall have much pleasure in placing before our readers.

ELEGANT PHARMACY.

THE publication in another column of the formulary issued by the Newark Pharmaceutical Association is an evidence of the greatly increased demand for the class of preparations therein referred to in the United States, where the proprietary medicine system has developed to an extent far exceeding that of this country, and has more than once occasioned attempts for legislative regulation. The desire on the part of pharmacists of presenting to the patient bitter and nauseous drugs in a pleasing and palatable form has given rise to the production of a multitude of preparations, as mentioned by Mr. HOWDEN, in his interesting remarks on Pharmacy in America, at an evening meeting of the Society during the last session. In fact, this business has grown to such an extent that we are informed it is sometimes necessary to keep, for dispensing purposes, half-a-dozen preparations bearing the same name, but emanating from different makers. This is due to the practice of certain physicians and apothecaries who patronize and prescribe the productions of particular pharmacists, a custom somewhat similar in effect to one met with occasionally in this country, to which attention has before been drawn in the pages of this Journal.

To counteract this evil the Newark Pharmaceutical Association has issued its formulary, while the Maryland College has proposed to treat these compounds as nostrums,—the mode of preparation of which is withheld, or, if published, yields a different article,—and to refuse to dispense them unless made by formulæ approved by the College.

Another side of the question is alluded to by the *American Journal of Pharmacy*, which says that

* See PHARM. JOURN. 3rd series, No. 17, p. 321.

some of these preparations are so destitute of medicinal properties, but are so agreeable to the taste, that they may be taken until, gradually, through the alcohol they contain, they create an appetite for alcoholic stimulants. This doubtless would be a disadvantage outweighing by far any benefit accruing from the pleasing appearance and the agreeable taste.

We find it stated, in a recent number of *Galignani's Messenger*, that the Mayor of the 1st arrondissement of Paris, on a report of the Comité des Ambulances, has conferred on Mr. Swift, English chemist, of the Place Vendôme, a medal of honour, for his energetic services during the first siege of Paris. This mark of high satisfaction was accompanied by a diploma, declaring that the recipient's exceptional devotedness and attention had entitled him to the gratitude of the French people.

Our newspapers and magazine covers are so overladen now-a-days with announcements and testimonials of wonderful cures and extraordinary effects of some quack nostrum with a long name, but about the composition of which we are supposed to know nothing, that it really would be a relief if we could have plain old Gerard back amongst us again, turning almost our entire British flora into a medical garden. The leaves of *Polygonatum multiflorum* appear to have been in his time most efficacious in removing the marks of bruises, for, beaten into a paste, and applied to the injured part, they were said to remove all external appearances, and to cure, as Gerard himself says, "any bruise, blacke or blue spotts gotten by falls or woman's wilfulnesse in stumbling on their hastie husband's fists, or such like."

The island of Nissiros, one of the Sporades, in the Grecian Archipelago, is of volcanic formation, the centre of it consisting of the crater of a large extinct volcano, so much impregnated with sulphur that cultivation is impossible. This sulphurous substance appears to be encroaching yearly on the arable land. A few years since, the Ottoman government established a manufactory for refining the sulphur found in the crater of the volcano, but hitherto little has been produced. If this establishment were worked on a large scale, it would afford a considerable amount of employment to the inhabitants; but some Nissiriotes who had been engaged in the work, having all of them died within a short time, the natives are unwilling to engage themselves in the labour for fear of a similar fate.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

SCHOOL OF PHARMACY.

Session 1871–2.

The Council has the pleasure to announce having made arrangements by which it is enabled to offer to fellow-members and associates the following complete course of instruction in chemistry, botany and materia medica.

A course of thirty lectures by Mr. Coomber, F.C.S., on Elementary Inorganic Chemistry, every Tuesday, at 7.30 p.m., commencing in October.

A course of thirty lectures by Mr. Coomber, F.C.S., on Elementary Organic Chemistry, every Tuesday, at 8.15 p.m., commencing in October.

A course of sixty lectures by Mr. Leipner, on Botany, Physiological, Economic and Systematic, every Monday, at 7.30 p.m., commencing September 18th.

At the conclusion of this series, that is in May next, an examination will be held in each subject, at which each student is required to present himself.

Tickets for the entire series will be five shillings for members and associates, provided the holder complies with the condition of presenting himself for examination, and shall have attended not less than twenty-five lectures in each course, in accordance with the regulations of the classes, if not, the fee will be ten shillings. The ticket will admit to either one, or the whole of the above series, but students are earnestly advised to abstain from entering for more courses than they can reasonably expect to follow up.

As the botanical lectures commence on Monday, the 18th, it is hoped that every principal will at once acquaint the assistants and apprentices of his establishment with the facilities offered for their scientific culture, and will do his best to further the efforts of the Council, some member of which will shortly call for an answer to this application.

Tickets for the above lectures may be obtained of the following gentlemen:—Mr. Stoddart, North Street; Mr. Schacht, Clifton; Mr. Pitman, Redcliff Hill; Mr. Taplin, Corn Street; Mr. Martin, Redland; Mr. Stroud, Wine Street; Mr. Townsend, Union Street; who will be happy to give any further information which may be desired.

Through the kind offer of the late President, Mr. Stoddart, the Council is also able to announce a series of about twenty-five lessons on the chemistry, botany and materia medica of the Pharmacopœia, adapted to the requirements of those associates of the Society who are preparing for the examinations at Bloomsbury Square. Mr. Stoddart declines to accept any payment for his labours, but agrees with the rest of the Council in the propriety of charging a fee of £1. 1*s.* for attendance at these lessons, the proceeds being arranged to go to the formation of a fund to meet the expenses of a pharmaceutical museum, or some similar educational object. The lessons will be every Tuesday and Thursday evening, commencing September 19th.

Tickets for this course to be obtained only at Mr. Stoddart's, North Street.

Mr. Coomber is also prepared to offer a course of practical laboratory instruction on Friday evenings at the laboratory in Nelson Street.

The fee for this instruction is £1. 1*s.* per quarter, and the tickets are to be obtained of Mr. Coomber only.

G. F. Schacht, *Hon. Sec.*

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Tuesday Afternoon, August 1.

Mr. D. HANBURY read a paper on

WILD RUE OR HARMAL SEEDS (*Semen Harmalæ*).

BY DR. F. A. FLÜCKIGER,

Professor of Pharmacy and Pharmacognosy in the University of Bern.

One of the plants named in the Non-officinal List of the *Pharmacopœia of India* is *Peganum Harmala* Linn., the seeds of which have long held a place in eastern medicine, and are an article of the Materia Medica respecting which Dr. Waring the author of the pharmacopœia in question, remarks that further investigation is desirable.

Although the following notes do not tend much to elucidate the therapeutical properties of this drug, regarding which information is most wanted, they may not be without some value as a contribution to its pharmacological history.

For convenience of reference, I have arranged my remarks under distinct heads.

Botanical Origin.—*Peganum Harmala* Linn., belongs to the Order *Rutaceæ*. It is a strong-smelling, herbaceous plant from 1 to 3 feet high, found wild in Southern Europe, Asia Minor, Egypt, Arabia, North Western India, and Southern Siberia.

History.—The plant is the Πήγανον ἄγριον (Wild Rue) of Dioscorides, Πήγανον being the name still applied in Greece to several species of *Ruta*. The seeds were used medicinally by the ancient Greeks as they are to this day in India, where they are chiefly known by the old Arabic name of *Harmal*. In Europe they were formerly much employed as *Semen Rutæ silvestris*, and as such are enumerated among the simples of several of the early London pharmacopœias.

Description.—The seeds are of a dark brown, 1¼ lines in length and ½ to 1 line in diameter, variable in form, but usually conical or with a semilunar or crescent-shaped outline, always angular, and rugose on the surface. They have an aromatic taste resembling rue, with some bitterness.

Microscopic Structure.—The testa is built up of two distinct layers, the outer forming a spongy tissue which consists of large, thick-walled cells. The cells of the inner layer are of a somewhat cubic form showing a peculiar, undulated outline. The albumen exhibits the usual thick-walled cells, the embryo consisting of a more delicate tissue. These cells contain chiefly albuminous matters, fat and essential oil.

Chemical Composition.—The most interesting fact concerning these seeds which immediately claims attention, is the magnificent green fluorescence which they impart to alcohol of about 75 per cent.* This optical power is partly due to a substance called *Harmin*, and partly, it would appear, to the formation of a peculiar colouring matter named *Harmala-Red* which has not yet been fully examined but which does not pre-exist in the fresh seed.

Fritzsche has showed that the seeds yield 2 to 3 per cent. of an alkaloid termed *Harmalin*, which is contained in the outer coat or testa. It is obtainable in colourless crystals, sparingly soluble in water or in ether, but more readily in alcohol, the solutions being of a bitter taste. Its composition is indicated by the formula $C_{13}H_{14}N_2O$.†

By heating the bichromate of harmalin, another alkaloid, *Harmin* ($C_{13}H_{12}N_2O$) is produced, of which about 1⅓ per cent. may also be obtained directly from the seeds. Harmin forms colourless crystals and colourless or slightly yellow salts. The alcoholic solutions of these compounds exhibit, when dilute, a blue fluorescence.

Further details respecting these alkaloids, condensed from Fritzsche's original papers, may be found in Gmelin's *Handbook of Chemistry*,* as well as in Husemann's *Pflanzenstoffe*.†

Uses.—In the East, stimulant, anthelmintic and even narcotic virtues have long been attributed to harmal seeds, but accurate observations respecting their medicinal powers are still required.

In Southern Russia a red dye, asserted to be both brilliant and permanent, is extracted from them. Finally they have been grown as an oil-seed.

* It may be observed even with a single seed.
† C = 12, O = 16.

* Vol. xvi. (1864) 103. † Berlin, 1870, page 76.

Dr. ATTFIELD read a paper on

A METHOD OF OBTAINING DISTILLED WATER ECONOMICALLY.

BY C. A. STAPLES.

Very few words need be said about the value and importance of distilled water. I do not write a treatise to prove a fact patent to every chemist, but knowing the great inconvenience many experience where they are not in a position to obtain a supply of it promptly, I wish to point out to them an easy and inexpensive arrangement by which an abundance is brought within the reach of every householder, viz., by the very simple expedient of converting the kitchen boiler into a still.

I first tried the experiment about twelve years ago in the simplest manner, not knowing what difficulties or even danger I might experience from its use, but I have found none. A few improvements have since been added, and I now purpose describing the whole plan for the benefit of all who may adopt it.

The boiler is a small cast-iron one, such as is usually supplied with the kitchen range for a small private family; it is self-filling by a small cistern and ball-cock in the usual manner. This cistern having cold water constantly flowing through it, I thought that it would act as a condenser, and it will be so called in the following description.

The lid of the boiler is closed by a paste of castor oil and whiting, which does not harden. The top plate has a hole drilled in it at the back corner near the wall, into which a piece of stout brass tube,‡ about nine or ten inches long, is fixed. To the top of this a piece of half-inch tube of *pure tin*§ is fitted, bent to an angle of about 60° or 65°, which, passing through a hole in the brickwork at a regular fall of about 25° or 30°, projects a few inches beyond the other side of the wall, where the end, slightly contracted by a file and curving downwards, is received into the enlarged mouth of a similar piece of tube, into which it fits sufficiently firmly without any joint or cement. It then enters the condenser near the top, is curved half round the inside out of the way of the ball, and passes out at the centre of the bottom, being secured to the condenser by screw joints; that at the top may be an ordinary brass one, but the lower one should be cast in pure tin, or if a brass one is used, it must be carefully tinned inside and out, for although not in immediate contact with the distilled water, a slight moisture might collect on it and injure the water.

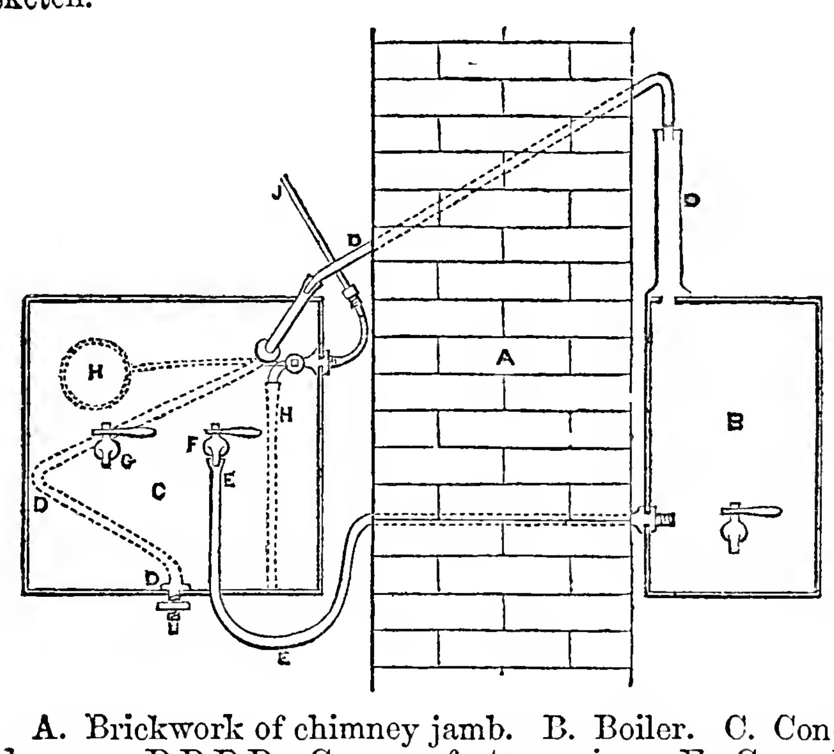
The lower end of the pipe should be tied over with muslin, or closed and pierced with fine holes, since insects, attracted by the warmth and moisture, might enter it in the night. In fact, the greatest care must be taken to ensure the purity of the metal, and that the inside of the pipe, from the point of condensation, is protected from any metallic or other contamination. The condenser should be much larger than usual, and have a lid

‡ Any piece of tube will do. Mine is a piece of a gas pillar, such as is screwed into a counter.

§ For a very large boiler a ¾ or even 1-inch pipe might be required, and the boiler should be made of wrought iron.

fitting *inside*, or steam will collect on it and flow down the outside of the condenser. It should stand on a stool with a hole for the pipe to pass through, under which the jar to receive the distilled water could be placed out of the way. The ball-cock should have a piece of pipe soldered to the nozzle, that the cold water may reach the bottom of the condenser. The pipe for feeding the boiler should come from about the centre of the condenser and curve downwards, so that a portion may be below the bottom of the boiler; for without this precaution the heated water would circulate to and from the condenser, and the water would soon become nearly as hot as that in the boiler itself. This simple precaution effectually prevents it, as the heated water will not pass through the cold part of the pipe below it without pressure. It should also be furnished with a stop-cock; all the joints should be secured by a few disks of stout brown paper over the flange, which, when drawn tight by the nut, effectually prevent leakage, and are easily removed if required for alteration, repair or cleansing. But if they are fixed with lead cement, they become so firm that they cannot be removed without injury. The condenser should have a waste pipe, unless the main cistern has a stop-cock to shut off the whole supply at night, or the condenser may overflow, since the ball-cock must necessarily work easily, and a slight leakage might be expected. The hole in the brickwork should have a piece of iron pipe cemented into it, to form a regular slope for the steam pipe, as it might drop into the hollow space and water collect in it.

I found the experiment very successful, the supply of distilled water being abundant and pure enough for any purpose. It is perfectly self-acting, the boiler fills itself and the water distils itself. It does not cause any inconvenience, interfere with any domestic or culinary operation, or limit the use of the boiler; on the contrary, it is greatly increased, as an abundant supply of heated water may be drawn from the condenser, care being taken to close the stop-cock and keep it closed for ten or fifteen minutes, or until the heated water is replaced by cold. It is perfectly safe, as the steam escapes freely through the tube, and the lid of the boiler, although steam-tight, may be raised with the thumb and finger. Little attention is required beyond placing a vessel to receive the distilled water and seeing that it does not overflow; the supply being so copious that sometimes, while cooking a dinner for a moderate family, several gallons will come over. I have found it difficult to give a perspective view of the apparatus, as some part must be concealed by the projecting brickwork, but hope it may be sufficiently understood by this partly sectional sketch.



A. Brickwork of chimney jamb. B. Boiler. C. Condenser. D D D D. Course of steam-pipe. E. Curved tube for feeding the boiler. F. Stop-cock screwed to condenser. G. Cock for drawing heated water from condenser. H H. Ball-cock, with tube for cold water to reach the bottom of condenser. J. Pipe communicating with main cistern. This pipe need not be large, as the water will never flow much larger than a goose-quill. Mine is only $\frac{1}{4}$-inch, but for a very large boiler I should think one $\frac{3}{8}$th of an inch would be ample.

Mr. Savage pointed out one or two objections to the method.

Mr. Baildon said that fifteen years ago he had occasion to fit up a small range. This range at one side had a high-pressure boiler, and he got inserted a valve that should be shut or left open. When open, the steam entered almost immediately, and from that day to this he had not had difficulty in getting distilled water.

Mr. Bottle said that this was a similar application to that which he used twenty-five years ago.

Mr. Williams stated that one thing in connection with this was, that the excise insisted on their paying still-licence for the right to distil water.

Mr. Baildon remarked that it was ascertained some time ago that that was not the case.

Mr. Williams said that he thought Mr. Baildon must have been misinformed.

Mr. Baildon stated that he had discontinued taking out a licence for many years.

A Member asked whether it was because Mr. Baildon had a steam engine, so that he could get distilled water from it, that he escaped the excise? If he had a still, he would have to pay for it.

Mr. Baildon said that he had not a still.

Dr. Attfield: Then the Excise allow you to distil because you have not a still on the premises?

A Member: Mr. Baildon has a steam-engine.

Dr. Attfield: Then the position is this:—you may have a still if you call it a steam-engine.

Mr. Mackay said he thought that if the plan proposed by Mr. Baildon were adopted, and if it became known to the Excise, the chemists would have to pay 10*s*. 6*d*.

Dr. Paul stated that he had been in communication with the Excise authorities on the subject, and, in answer to whether the chemists might use a still for distilling water, was told that, although the Inland Revenue had power to grant exemption from the provisions of the Act as to licences, there was such extreme difficulty in drawing the line between cases subject to payment of duty, and cases which might be exempted from it, that they were often at a loss what action to take, and found it practically necessary to insist on the payment of licences from every one who had a still, that was, a vessel capable of the distillation of alcohol. Although there was a willingness to remit the licence when it was objectionable, they found it impossible to do so. Some years ago he was engaged in a manufacture where distillation was carried on. They had several stills, for all of which they had to pay licence, and it was a somewhat serious tax. He applied to the Income-tax Commissioners, and requested them to allow him to use the stills without a licence. In that case they did give permission, but the material distilled was tar. He had some difficulty in making them understand that it could not be used for the distillation of alcohol, but so soon as they were satisfied of that they granted his request; and he believed that they would do the same in other cases if they were satisfied that it was for such purpose.

Microscopes and Photographs.

Dr. Edwards exhibited a number of excellent microscopes and beautiful photographs. The photographs represented the old and present laboratories of the Society and portraits of some of the founders of the Conference. The microscopes were remarkable both for cheapness and superior quality.

The next paper was one on—

Pharmaceutical Ethics.—*Re* "Apprenticeship."

BY S. R. ATKINS.

We venture to claim for the subject now introduced to your notice the merit, at least, of practical importance.

It is evident, on a moment's reflection, that the future of pharmacy is vested in the hands of our young men.

We are all alike interested,—the trainer, the trained, and the public on whom we depend. The present generation of principals were in their day pupils, whilst the pupils of to-day will, in their turn, be teachers. But apart from the abstract or general merits of the question, there are special and particular aspects of it at the present moment which deserve our careful consideration.

Let us inquire what *Apprenticeship* means. It is an arrangement through which a youth is placed by his parents or guardians under the care of a third person to learn a profession or trade, the remuneration for which education is called "the premium."

It is relevant here to inquire if this system be a good one and desirable to be continued, for we scarcely need remind the readers of 'The Year Book,' and of the interesting article it contains on American pharmacy, that the *institution* of apprenticeship, as our Transatlantic Cousins would term it, does not exist amongst themselves. We are disposed to answer this question affirmatively, but, at the same time, endeavour to show what modifications are needed.

We venture on this subject with some degree of diffidence, remembering how ably and comprehensively the entire field of pharmaceutical ethics has been surveyed by Mr. Ince, a name, by the bye, worthy of the highest respect by all pharmacists; we refer more particularly to the elaborate paper read at the Nottingham meeting.

It is with great satisfaction we also recognize the ably expressed opinions on this and kindred branches of the same subject of Messrs. Giles, Schacht, Brady, Benger and others.

On the other hand, the question is by no means as yet threshed out; indeed, it is doubtful if it has yet been fairly grappled with, whilst the difficulties inherent must, from the nature of things, increase for a time at least. A statement of the facts in the first place, and of suggestions remedial in the second place, will probably be the best plan on the present occasion.

1st. For the facts.

Fewer apprentices are being taken. Of these it is to be feared comparatively a small proportion are being trained in establishments competent for the task. The results are evident in the Preliminary Examination. Those who, like myself, are familiar with the facts of provincial education, know that the failure of our youth in that initial test scatters dismay amongst their own ranks and that of their friends. The standard of that Examination it would not be wise to lower; if that be done, the subsequent or higher rungs of the ladder must be reduced in proportion. To say the least, such a course would be an anachronism in an age of growing culture in the nation generally; and when from ourselves special demands are made, as the result of that chartered status, so long nobly fought for, and at length secured. Our classic houses both in town and country have not yet felt the pressure, but that the inexorable logic of facts they will sooner or later have to acknowledge there can be no doubt; the supply of young men is not keeping pace with the demand. Many personal friends of mine are declining the responsibility of taking apprentices. Men competent for the work say, "We have done our share in this matter, and will now leave it to others." The result is, our youths are being relegated to third-rate houses, in which "the premium" is the "consideration" in more senses than one, where the habit of industry may be acquired, and the charms of variety are freely offered, but where chemistry and pharmacy are conspicuous only for their absence.

Such, in brief, are the facts of the case. And now what remedial measures can be suggested? for we all know how much easier it is to criticize than construct, to analyse than to synthesize.

We start then from the position that the ordinance of apprenticeship is in itself sound and good. What can be done to bring it into more harmonious working with the other gear of pharmaceutical machinery? Confessedly the difficulty is for the transition period of the next few years. That the thing will come right in the end there can be no doubt.

Firstly, we insist on the Preliminary Examination or its equivalent, one of the University Local Examinations, being passed as a prerequisite of apprenticeship.

The advantages thus secured would be immense, and felt at each subsequent stage. An eligible start would have been secured for the youth, whilst the master is placed in a less invidious position. A lad submitting to the test immediately on leaving school should be in "form" to win the race; whilst for ourselves, as men of business, we are conscious of the fact, whatever our capabilities may have been when school-days ended, and we had our first introduction to the pestle and mortar, that at any rate *now* we cannot accept the responsibility of teaching Ovid or Euclid.

We urge then a liberal and prolonged school-training, to be continued at least until sixteen years of age; this will necessitate the ranks of pharmacists being recruited from the substantial section of the middle class; *pari passu*, this will be a gain, for whilst we gladly acknowledge the fact that intellectual force as well as moral quality is not confined to any rank of society, there clearly would be less disappointment if those who joined our order were more equally weighted, not only at starting in educational advantages, but in pecuniary prospects; we might then hope to see a diminution of those wretchedly small businesses, the cause of much more heart-breaking than is indicated in the *Gazette*, or the lists of our Benevolent Society.

The next point to which we advert is the *shortening the term of apprenticeship*. Three years, or at most four, will be regarded as sufficient. The contraction of the time must prove a mutual benefit: less to be played with, concentration of energies will be aimed at and achieved.

An improved treatment of our apprentices will inevitably arise as the result of mutual confidence and respect. At its best estate, and under the most favourable circumstances, the pursuit of pharmacy has many drawbacks, but what it must be when these conditions are wanting, it is sad to think,—long hours, short holidays, much work and sometimes dirty too; this is, alas! too often the plain prose which destroys all the early romance of coloured carboys and mirrored glass.

Let us not be misconstrued; we have no contention with work, and plenty of it too. The best men in any calling are those who have attacked its initial drudgery with brave hearts and strong arms, having faith in the law that no lasting or proportioned structure can be reared on an imperfect foundation. Only let us as principals see to it, that the conditions under which that work is done are not too exacting.

We advance to the last consideration and the most important. What are the just claims our apprentices have on us for instruction, and to what extent are those claims at present being met?

By the deed of indenture we undertake not only to provide sufficient and suitable board and lodging, but we also covenant to teach the art and mystery of pharmacy. Let us fairly look this matter in the face; where do our responsibilities begin, and where do they end? We assume the Preliminary Examination, or its equivalent, has been passed; this, as we have already argued, must be insisted on, as a *sine quâ non*.

A youth of sixteen enters an establishment with this credential in his hand that he has received a liberal and classical education. Here then we start, and the goal at the end of the course is the Minor Examination of the Pharmaceutical Society. To enable a young man to acquit himself satisfactorily at that ordeal should be our aim; and in making this statement, we take it for granted the other qualifications which go to make a first-class business-man are not overlooked, namely, method, order, punctuality, address, etc.

In the closing remarks of this paper, we desire to avoid everything savouring of uncharitableness towards a body of men deserving the highest respect; we refer to the great body of our provincial brethren. These men are for the most part conducting their businesses with credit and success, but, not having possessed in their early days the advantages now so readily procurable, they are willing to confess their inability to impart the requisite knowledge with which to approach the 'Minor.'

What is the remedy for this state of affairs?

Bloomsbury Square is not available in the provinces; local schools are few and far between; in fact, they are wellnigh out of our calculation; invaluable as centres of light, where their influence is felt, they but make the darkness beyond more visible. That something at once must and ought to be done, the large proportion of rejected candidates at our examinations painfully attests.

We have attempted the diagnosis of the disease, and ask the remedy; as a humble contribution to the same, we suggest that wherever there are some half-dozen young men in a town needing and seeking instruction in pharmacy, that is, the general course of reading suggested by the Minor Examination, they club together, during the winter months engage a room, and respectfully solicit the direction of the most able pharmacist in the place to guide their studies. Further, that the Council of the Pharmaceutical Society foster provincial education with their recognition and *active* sympathy; that competent men in country towns be urged to undertake this work, that class books be suggested, small cases of apparatus for the study of analysis be granted on loan, and the results of such labours find their recognition in the pages of the PHARMACEUTICAL JOURNAL.

Salisbury, July 5, 1871.

The CHAIRMAN said this was a subject on which the whole afternoon would hardly be long enough to hear those most capable of giving an opinion. Instead of entering into the subject himself, he would rather hear the opinion of others, such as his friend Mr. Deane. With regard to the question of education, he might remark that the questions now put to their apprentices were so easy that he would be surprised if a lad could not answer them. It had been stated as an objection, that if they gave the lads so much time for learning as some desired, they would not do enough of work. If they gave them a proper amount of study with their proper amount of business, he thought they ought to see that they did their work. He himself was apprenticed in a locality in which he was made to do drudgery, but which, he was thankful to say, he was obliged to learn. In his time of day they had no holidays. He began at half-past six o'clock in the morning, and left off at eleven at night. These were the hours, and he had no holidays, Sunday or Saturday. When he went to Bath he was astonished when his master offered him a fortnight's holidays. His own young men had an hour in the morning to themselves, and he had a good deal more work done than if he did not let them out. He recollected when he was ordered to do a great many things which lads nowadays would consider beneath them, and would not do. The force of example went a good deal further than anything he could tell them. One of his young men had seen him night after night at the microscope, and this young man might at first have thought that he was a very stupid fellow; but by-and-by he came to take an interest in the matter, and became as good a microscopist as there was in England. A good deal depended on the way in which they treated their young men. If they told them they must do such-and-such a thing, they would not enter into it with the same heart as if they had been persuaded to do it. He thought the paper was one of very great importance.

Mr. DEANE said his experience was much the same as that of Mr. Stoddart; but he considered that the altered conditions of the times rendered the responsibility of taking apprentices much greater than it was thirty or forty years since.

Mr. SCHACHT said the subject immediately before the meeting was one he felt scarcely competent to speak about. It was this conviction that had hitherto kept him silent upon this one section of the subject he had so much at heart, pharmaceutical education. He candidly admitted he did not know how to meet it, it was beset with so many difficulties. In the first place a master, merely because he was a pharmacist, was expected to possess that great and special gift, the ability to guide and direct the moral training of a youth at the most critical period of his whole life. To add to his difficulty, it might be quite possible that two entirely opposite characters became his charges at the same time. It was also expected of him, not only that he should be a good pharmacist, but also that he should possess the qualities of a good schoolmaster, and that, contrary to general experience, he should be as well able to teach as to learn. These were some of the difficulties of the case, and the only solution that suggested itself consisted in the separation of some of these duties. If instead of it being the habit and rule that masters should receive youths into their houses as well as receive them into their businesses, an arrangement could be made whereby the youths' boarding and lodging could be done elsewhere, one great difficulty would be removed, and the master would be absolved from the charge of the moral training of his apprentices; and then it might be possible that some of the best houses who now, because of their disinclination to accept this charge, decline to take apprentices, would willingly offer their excellent professional opportunities. Again, as to the best method by which an apprentice could gain the scientific knowledge requisite to make him a good pharmacist, it seemed to him better that he should look for this outside his master's shop. It appeared almost too much to expect that the same man should be at once a good retail trader and an instructor in chemistry and botany. He did not mean that he could not help his pupil, but that he could scarcely be expected systematically to teach science; and all desultory work might as well be left alone. Would it not be better that during the time the apprentice was fulfilling his duties in the shop, certain portions of the day should be devoted to attending professional lectures, and some encouraging help given him in appropriating what he there heard? Speaking collectively, he thought the direction of their efforts should be to develope such a system of scientific education, away from the shop, as to make it unnecessary for the master to undertake that duty himself. The establishment of provincial centres with such classes as portions of their system was, he thought, the best means to this end; and he was glad to find the observations of previous speakers tend so distinctly in that direction.

Mr. MACKAY (Edinburgh) said that Mr. Schacht had referred to what occurred to the minds of the pharmacists in Scotland, as a very strange mode of procedure in binding apprentices throughout England. He wished to bring before the meeting the fact that in the whole of Scotland, as far as he was aware,—and he knew the arrangements of the pharmacists throughout the country very well,—he did not think there was a single case where a premium was paid and where a youth was boarded and taught his business. The very reverse was the case; and his object was to impress on the

Conference, that the system which Scotland had adopted had not only been longer in existence, but had worked so admirably that he felt sure their friends in the South would be going in the right direction if they were to take a leaf from their book. Some years ago, before the Preliminary Examination was adopted, it was arranged that no youth should be taken by any chemist or druggist—at all events by no Member of the Pharmaceutical Society—unless his parents or guardians agreed to pay fees for his attendance on certain classes; the master, on the other hand, becoming bound to furnish him time for attending these classes. The system followed and still pursued was this. A fairly educated youth about to be apprenticed to a druggist was told, not that the period was to be three or four, but five years. The exceptional cases of three or four years arose generally from a lad being pretty far advanced—say seventeen or eighteen years old,—in which case it was no uncommon thing to shorten the period. Five years might therefore be considered the usual term. Now, during these five years the lad was not kept by his master, but received a salary of £10 per annum. The lad thus apprenticed went to the business as a rule at 9 A.M., but if he had opened the shop at an earlier hour, he then got permission to go home to breakfast for a suitable time. Those who came with their breakfast got an hour and a half for dinner, and if this was early in the forenoon, then a few minutes were allowed in the afternoon for the apprentice to get refreshments. Such a plan had existed and worked in the most satisfactory manner for a very lengthened period. He might say, however, in regard to the Preliminary Examination, that he thought it now well understood by the leading pharmacists throughout Scotland that in the case of a young man applying to become an apprentice, in addition to the master giving time, it had become the rule that that young man must pass the Preliminary examination. Nothing had been so satisfactory as the determination that no young man should now be allowed to enter the Pharmaceutical Society unless he had passed that examination. He said this all the more strongly, because he had kept a register for situations for young men for many years, thus obliging employers who might want assistants. The young men were required to write a letter, stating their capabilities and the kind of situation sought for; and he told them frankly that the letters they wrote would be shown to inquirers, they had therefore every opportunity to be careful in their style of writing, as well as in their grammar and orthography. The Conference would be astonished if they saw the letters now and again put into his hands by men who had served the regular apprenticeship of three, four or five years to druggists. Such a state of things must end. By exacting the Society's examinations, they prevented the possibility of young men being allowed to apply for situations for which they were incapable. Many of them did not know the mere ordinary rudiments of the English language. It was a state of things which ought not to exist, considering the position which pharmacy now occupies. He concluded by strongly recommending the Scotch system to the consideration of their English brethren.

Dr. Edwards said he was not able to say that Canada represented the advanced guard, but it had assumed a very similar position to that of Scotland in this matter. The term of apprenticeship did not generally exceed four years, and the salary ranged from £10 the first year, £20 the second, £30 the third, and £40 the fourth. Four years, he believed, was the ordinary term, but very frequently three years were considered sufficient; and, as in Scotland, the apprentices did not reside in the house. The principal often resided in the country, or in another part of the city from the place where his shop or store was situated. He had experienced some of the difficulties which Mr. Schacht had suggested with regard to the social relationships of apprentices. The want would be better met by the apprentices residing in such families as were acquainted with their parents, or in such circumstances as parents might think proper to place them. He thought an agreement was better than the old system of indentures, and he was surprised when he read over some of the restrictions, such as not playing cards, not being allowed to smoke, nor to go out of the house without the master's permission. These were things which were curious, and belonged to old habits and customs. It was important for the Conference to keep in view that they had to provide men for the future. They could not over-estimate the importance of this, looking to the demand there would be from foreign countries. One important point they should not lose sight of was a thorough knowledge of book-keeping; and in the matter of stock-taking, some chemists were very much at a loss indeed. These were matters to which it was important that attention should be directed.

Mr. Atkins said he remembered reading a paper by Mr. Giles in the Pharmaceutical Journal, in which he advocated some system of boarding out. He (Mr. Atkins) could not say he had brought his mind entirely to agree with Mr. Giles's proposal. He could see the very great advantage, but also the disadvantage, of the proposed system. He feared the difficulty pointed out by Mr. Schacht would be enhanced were that plan carried out. That was in regard to the moral training. As to the provinces, Mr. Mackay's system would suit admirably for Glasgow and Edinburgh, and towns where classes could be obtained, but in other places it would not do.

The following papers were taken as read, owing to want of time:—

The Preparation of Liquor Bismuthi.

BY C. H. WOOD, F.C.S.

For the last two years I have frequently resorted to a process for the preparation of a liquor bismuthi, which would, I think, constitute a good process for a future Pharmacopœia, because, while it is very simple and is easily performed, it yields a product quite free from nitrate of ammonia, and eliminates all the impurities of metallic bismuth.

To proceed by this method, I first obtain pure anhydrous oxide of bismuth. A weighed quantity of this oxide is then digested with a mixture of citrate of ammonia and citric acid in strong solution for fifteen or twenty minutes at near the boiling temperature, after which a slight excess of ammonia is added, and the solution diluted to the required volume. The mixture of citrate of ammonia and citric acid rapidly and completely converts the anhydrous oxide into citrate of bismuth, which the ammonia afterwards added instantly dissolves.

The oxide of bismuth is best prepared from the subnitrate of commerce. A pound of the subnitrate is boiled for a few minutes with four pints of liq. potassæ, then washed by decantation and dried in a stove or water-bath. It forms a dull lemon-yellow powder, which is anhydrous and perfectly definite in composition, being represented by the formula Bi_2O_3. 100 parts of the subnitrate yield from 81 to 82 of oxide.

Instead of boiling the basic nitrate with the potash, digestion in an earthenware jar with frequent stirring for an hour or two may be resorted to. Care should be taken to employ liq. potassæ free from carbonate. As the oxide subsides with great rapidity, it is perfectly washed with ease and quickness by decantation. I have always found commercial subnitrate of bismuth to be quite free from copper, and any traces of arsenic or antimony which it might contain would be completely removed by the potash; consequently the oxide of bismuth must necessarily be of great purity.

The following formula is adapted to the preparation of a gallon of liquor bismuthi, having the same strength as the solution of the Pharmacopœia:—

Oxide of Bismuth	9 oz.
Citric Acid	16 oz.
Strong Solution of Ammonia .	12 fl. oz. or q. s.
Water	q. s.

Dissolve 8 oz. of the citric acid in 4 oz. of hot water, and carefully neutralize it with some of the solution of ammonia (about 7 fl. oz.), mixed with half its volume of water. Then add the other 8 oz. of citric acid, and when it has dissolved introduce the oxide of bismuth. Heat the mixture to near its boiling-point for about fifteen minutes, with frequent stirring, then add about a pint of water and introduce sufficient ammonia to dissolve the insoluble portion, and render the liquid slightly alkaline. Augment the solution to the volume of one gallon, and filter through paper.

It will be found upon heating the mixture that the pale yellow colour of the oxide rapidly changes to a pure white, and at the same time the insoluble portion becomes more bulky. These signs indicate the conversion of the oxide into citrate of bismuth; the digestion is continued for a little time to ensure the perfect completion of this change. The ammonia, subsequently added, should effect a complete solution, leaving nothing insoluble but the dust, etc., inevitably present in the powder taken.

As the oxide of bismuth employed is quite as definite a substance as the metal itself, it follows that the resulting liquor will be as uniform in strength as if prepared according to the process of the Pharmacopœia.

The Proposed Changes in the Nomenclature of the Pharmacopœia.

BY C. R. C. TICHBORNE, F.C.S., M.R.I.A., ETC.

Professor Attfield has lately proposed that certain changes should be made in the nomenclature of the British Pharmacopœia; that the modern notation should be used only, and that the terms employed should coincide with that notation. Thus in the present Pharmacopœia two notations are employed but only one nomenclature, and the framers of that work gave preference to that notation which harmonized with the old system; this, however, is now nearly obsolete.

Professor Attfield's Manual of Chemistry has made such rapid progress in public estimation, that it may be considered to have almost become the medical and pharmaceutical text-book of chemistry.

Its reputation is not one iota in advance of its merits, and as the originator of such a work, Professor Attfield's words come with even more force than they otherwise would. The general tenor of his recommendation is to the effect that we should retain some part of what is known as the Lavoisierian mode of nomenclature, but substituting the metallic names throughout for the alkalies and alkaline earths.

Thus we should say sulphate of sodium, sulphate of iron, carbonate of magnesium, etc., instead of sulphate of soda, sulphate of iron or carbonate of magnesia. Also that we should discard the old atomic weights and use the new atomic weights alone.

With all this, I, as one humble worker in the field of science, heartily agree. Fourteen years ago I advocated these new-fangled ideas as they were then termed, and have consistently used them in practice. So little were such views entertained at that time, that with one exception, there was not another chemist in Dublin who even acknowledged the probable correctness of such a system. What a change has been wrought in these fourteen years! This was the system used by Aug. Hofmann when the writer was at the College of Chemistry, and it will perhaps be in the memory of some of the gentlemen present that exactly a similar system is used in his (Dr. Hofmann's) Report on the Exhibition of 1862. In speaking of this matter in the introduction to that work, he says, "The symbolic notation employed in this report requires a few words of explanation here, and perhaps also of justification. It differs from the notation still in use only by the doubling of the equivalents usually assigned to oxygen, carbon, sulphur and a few other elements. Slight, however, as this change is, it suffices to alter materially the aspect of many formulæ, and to those who still adhere to the old notation it may give a little trouble which the reporter would willingly have spared them. For this reason, indeed, he hesitated a good deal before deciding to employ the modified notation. To this decision, however, he was ultimately brought by the reflection that the modified notation is essentially necessary to represent with the requisite clearness and precision the vast and daily multiplying class of substitution changes, and that on this ground only, if on no other, the double equivalents must ere long come into universal use." The author then uses the terms carbonate of sodium, sulphate of ammonium, etc. Dr. Attfield wishes to substitute a similar system for the Pharmacopœia, such a system that whilst giving due prominence to all the most firmly established theories of modern chemistry, also does away with such inconsistencies as calling one salt the sulphate of the oxide, and another salt, exactly framed upon the same type, the sulphate of the metal. It enables us to view all these salts as constructed upon one given framework.

But outside this the system does not go; and when from time to time extreme terms are introduced to convey special or extreme theories, they should not be considered in any system intended for general instruction, but should be strictly confined to the writers of original research. But at the same time the fraction of any science necessary for the furtherance of any other art, must harmonize with knowledge to which we have attained; thus far must we go and no farther. It is for this reason that I agree so thoroughly with what Dr. Attfield has advocated. I might, perhaps, object to a few of the individual names which he has proposed, but really these things are so much a matter of taste, and his paper has been so well and ably discussed, that I do not consider this the time or place to enter into such small matters.

Dr. Attfield makes use of a paragraph which seems to lay down a principle, which principle would, however, hardly agree with the practice of his own paper. Great prominence has been given to this supposed principle by some of the reviewers. Thus, an excellently-conducted one, the *Chemist and Druggist*, says, "Clearly he has proved his point, and shown that chemistry and pharmacy, though branches of the same science, have distinctive characters, and that it will be for the mutual advantage of both to adopt a nomenclature of their own."

Now, I must dissent from this view. A nomenclature is only a system for the conveyance of facts. It is not to be supposed that we could have two nomenclatures harmonizing equally, if at all, with facts. As well might we some years since, when the avoirdupois ounce was substituted for the troy ounce, have said that as the division of the pound gave 437·5 grains to the ounce (which was inconvenient), pharmacy should have an arithmetic of its own, and that 1 and 1 in mathematics made 2, but in pharmacy they should make 3. No! We must have the same chemistry for the philosopher, the same chemistry for the pharmaceutist, and the same chemistry for the medical man,—in other words, as near the truth as the science of the day will take us, and nothing but the truth. It was for this reason that I saw with pleasure that Dr. Attfield hit hard at such terms as *acidum arseniosum*, which, from a chemical point of view, are radically wrong. We are informed that there is not likely to be a new edition of the Pharmacopœia for some time, but I am quite convinced that when it does come we shall have the new atomic weights, and a binary notation and nomenclature in conformity with the new system alone. Thus will Dr. Hofmann's prophecy be fulfilled as regards another important branch of practical chemistry.

One of the proposed changes is, that the names should convey more accurately the actual chemical composition as found by analyses. Thus, it is proposed that the term oxyacetate of copper should be used for verdigris. The few cases met with in the Pharmacopœia similar to the above one are, I think, better got over by using trivial names, just as we in the Pharmacopœia specify a certain well-known quality of carbonate of calcium as chalk, although we have at the same time the pure article as far as ordinary chemical processes will give it. In fact, it is hard to say how the excess of oxide of copper found in the verdigris can be considered any more or less of an impurity than the silica found in the chalk. I am of opinion that we are rather too much inclined to view chemical decompositions as much too sharp and definite, and then in some instances to be too particular. Because we see a voluminous precipitate tumble down on adding hydrochloric acid to nitrate of silver, we are naturally predisposed to consider it as a perfect precipitation of all trace of silver; but, although such may practically be the case as far as our method of detection goes, it is really a rearrangement of the balance of forces which has a limit; and it is most probable that even with this the most definite of reactions, the precipitations is incomplete, and that, if we had instruments or reactions delicate enough, we should perceive such to be the case. That is to say, in nature there is no such thing as very sharp and hard lines. Thus, when we get a basic carbonate of magnesium on mixing carbonate of sodium and sulphate of magnesium in equivalent proportions, it is merely that some of the carbonic anhydride is partitioned off by the new arrangement of the forces; that the point where this partitioning off lies depends upon many circumstances, but principally that of temperature, and we get a precipitate of carbonate of magnesium, containing variable quantities of oxide of magnesium as an accidental impurity. Under such circumstances, should we not be nearer the truth by retaining the name carbonate of magnesium in this and similar cases, and give the notation as a hydrated carbonate of magnesium, and merely state amongst its characteristics that it contains generally 10 per cent. of oxide of magnesium?

I think the great difficulty in the perfect acceptation of the new nomenclature and notation in Pharmacy is, that most of the medical licensing bodies do not make it compulsory that the candidates should answer in the new notation. As long as it is optional with the medical student, it will never be perfectly adopted, for Pharmacy must sail in company with the practice of medicine. Now we find that in the year 1870 there were in this kingdom 1160 medical students registered, being much in excess of the pharmacists. With the Pharmaceutical student the acceptation of the new system is easy; chemistry is his principal and most difficult study. With botany it constitutes all his science; he must have both a theoretical and practical knowledge of it, or he is no pharmacist. He therefore will not mind a little more trouble, for the new system is a degree and only a degree more difficult. But chemistry hitherto has formed but a moiety of the medical student's study, and the little he did learn he looked upon as a matter of secondary importance. In such a case, if the student is presented with two roads, he will very materially take the short one.

Before concluding, I may as well state that I consider the nomenclature of the compound preparations of the Pharmacopœia open to a little revision; this would, however, be too long a subject to go into here. Thus I take it, that all those preparations should be named according to their most active therapeutic ingredient, the substances used as vehicles being ignored. If more than one active ingredient is used, it should be called a "compound" preparation. This is hardly carried out by the name 'tinctura camphoræ composita,' a preparation where there are 40 grains of opium to 30 of camphor; by the omission of composita from tinctura sennæ, or tinctura rhei, whilst such names as linimentum potassii iodidi cum sapone might be shortened by leaving out the latter part. I hope, however, we shall have as little change as possible; but when we do make any, let it be to keep pace with the progress of science. There is no danger of Macaulay's New Zealander appearing on London Bridge for some generations to come; therefore, there is a long period before it for Pharmacy to assert itself in this country. It is to be done by ever bearing in view "that banner with the strange device—'Excelsior.'"

Votes of Thanks.

Dr. Proctor moved a vote of thanks to the authors of the papers which had been read at the Conference.

Mr. Kinninmont seconded the motion, which was unanimously agreed to, and the thanks of the meeting were conveyed by the Chairman.

Mr. Schacht moved that the cordial thanks of the Conference and non-resident members be given to Mr. Mackay, Mr. Baildon, and the other members of the Local Committee for their successful efforts in organizing the present meeting, and for the excellent manner in which they had made all the necessary arrangements. He said they had been fortunate in having been received in such a cordial manner, and with such hospitality and enthusiasm, by the Committee in Edinburgh.

Mr. Savage seconded the motion, which was supported by Mr. Atkins and Dr. Attfield, and cordially agreed to.

Mr. Baildon (as Chairman of the Local Committee) returned thanks.

The Chairman then read a letter from Mr. Reynolds as follows:—

"*Leeds, July 29th*, 1871.

"My dear Mr. President,—The effects of my late accident incapacitate me from joining in the various gatherings, whether for business or social objects, which happily blend at our Annual Conferences.

"This deprivation causes me regrets, but they are greatly tempered by a consideration of the perfect success of our Association, and the belief that in the 'Year-Book of Pharmacy' the Conference has found a talisman which will secure the lasting adhesion of its large and rapidly-increasing roll of members.

"I have also to ask that I may not again be nominated as one of the General Secretaries.

"My fellow-members have a right to the statement respecting the past management of the Conference which I now desire to make. The general direction of its affairs has been in the hands of Professor Attfield, and month by month and year by year he has devoted his valuable time to its general guidance, and not less to the performance of the minute duties of routine, with a constancy, forethought and method that has been simply perfect. Of the success of the present meeting, and its many pleasant circumstances, no one can feel a doubt who knows anything of the attractions of "modern Athens," and of the earnestness and executive abilities of our brethren who have offered us welcome to the Conference.

"With grateful thanks to those colleagues and other fellow-members, to whom I am indebted for so many evidences of kindly feeling during an intercourse of eight years,

"I am, my dear Sir,
"Very faithfully yours,
"Richd. Reynolds."

Dr. ATTFIELD referred at some length to the great services which had been rendered by Mr. Reynolds, and said they all regretted his absence from the Conference.

It was unanimously agreed to convey to Mr. Reynolds an expression of their regard towards him.

ELECTION OF OFFICE-BEARERS.

The following office-bearers were then unanimously elected:—

President.

H. B. BRADY, F.L.S., F.C.S., Newcastle-on-Tyne.

Vice-Presidents who have filled the office of President.

H. DEANE, F.L.S., Clapham Common, S.
Professor BENTLEY, F.L.S., M.R.C.S., 17, Bloomsbury Square, W.C.
D. HANBURY, F.R.S., F.L.S., Clapham Common, S.
W. W. STODDART, F.C.S., F.G.S., Bristol.

Vice-Presidents.

J. INCE, F.L.S., F.C.S., London.
J. WILLIAMS, F.C.S., London.
R. REYNOLDS, F.C.S., Leeds.
W. D. SAVAGE, Brighton.

Treasurer.

G. F. SCHACHT, Clifton, Bristol.

General Secretaries.

Professor ATTFIELD, PH.D., F.C.S., 17, Bloomsbury Square, W.C.
F. B. BENGER, 1, Market Place, Manchester.

Local Secretary.

T. GLAISYER, 11, North Street, Brighton.

Other Members of the Executive Committee, 1871–1872.

M. CARTEIGHE, F.C.S., London.
T. B. GROVES, F.C.S., Weymouth.
F. SUTTON, F.C.S., Norwich.
C. EKIN, F.C.S., Bath.
J. MACKAY, F.C.S., Edinburgh.
T. GREENISH, F.C.S., London.
C. UMNEY, F.C.S., London.
F. C. CLAYTON, Birmingham.
W. SMITH, Brighton.

Auditors.

H. C. BAILDON, Edinburgh.
J. SCHWEITZER, Brighton.

A cordial vote of thanks was then awarded to the Chairman, and the proceedings of the Conference were brought to a close.

Parliamentary and Law Proceedings.

THE ALLEGED POISONING BY A LADY.

On Friday, September 8th, Christiana Edmunds was again brought up on remand, charged with the murder of Sydney Albert Barker.

Another boy deposed that he had been sent by a lady, whom he believed to be the prisoner, to purchase chocolate-creams at Mr. Maynard's.

An assistant to Mr. Maynard deposed that on various occasions when children had been to purchase chocolate-creams a boy was sent after them in order to watch to whom they were given: and a boy in Mr. Maynard's service deposed that on one occasion he saw the messenger delivered the creams to Miss Edmunds, who was waiting for them.

Some children were also examined, who said that a lady, whom they believed to be the prisoner, had given them chocolate-creams in the street, which they ate, and that they were afterwards ill.

Mr. Maynard, the retail seller, and Mr. Ware, the wholesale manufacturer, deposed that they had never before had any similar complaint concerning the chocolate-creams.

The prisoner reserved her defence, and was committed for trial on this charge, and also on another of attempting to poison the wife of Mr. Garrett.

MYSTERIOUS DEATH OF A SURGEON.

An inquest was held on Wednesday, September 6th, at Birkenhead, on the body of Mr. James Douglas Murray, surgeon, who was found dead on Tuesday afternoon under somewhat mysterious circumstances. On Tuesday forenoon he visited her Majesty's ship 'Eagle,' at present used as a training-ship for the Naval Reserve, and attended to his business as usual, and he then appeared to be in his usual good health. In the afternoon, shortly before five o'clock, he was found lying dressed on his bed, apparently in a fainting fit, but the medical men who were called in found that he was dead. On a chair close to the bed there was a bottle which contained chloroform, and it is supposed by the deceased's friends that he had taken an overdose of this anæsthetic to allay toothache, from which he had been suffering. The deceased was only twenty-three years of age, and appeared never to have suffered from any bodily ailment. In his bedroom some bottles were found, and one of them had contained prussic acid. The inquest was adjourned for a *post-mortem* examination of the body.

POISONING BY CARBOLIC ACID.

An inquest was held on Saturday, September 9th, at Wimpole Street, Cavendish Square, on the body of Mrs. Jane Jackson, wife of a physician. Mr. Paul Jackson, husband of deceased, said that on Wednesday night last he heard that she was taken ill. On inquiring the cause the servant informed him that it was from the same cause as before, viz. excessive use of spirits. He went to bed. The following morning the servant informed him that deceased was worse, and he went to see her. Ten minutes after leaving the bedside he was called up again, and found she was dying. Dr. Murchison was fetched, and he found the towels used by deceased smelt of carbolic acid. He kept carbolic acid in his surgery, which, on account of the great craving deceased had for spirits of any kind, was usually kept locked. He believed she took the carbolic acid in mistake for methylated spirit, both of which were kept in gallon stone bottles. He believed that after she had taken the carbolic acid she took some ether, which made her insensible to the pain arising from the carbolic acid.

Mr. Charles Jackson said that on Wednesday night, by his father's instructions, he went upstairs and found deceased lying on the floor. Having seen her so before, he left her, and with his father visited her in about two hours after. She was then in a stupor, which they concluded was from intoxication. He visited her again the next morning, shortly after which she expired. He had since discovered carbolic acid on the bedclothes. He believed she took the carbolic acid from the surgery in pure mistake.

Kate Walsh, a maid-servant, deposed to finding deceased in the bedroom on Wednesday night in a state of insensibility. The same steps were taken as on former occasions, viz. giving her tea, etc., to restore her.

Dr. William Cayley, M.R.C.P., Professor of Anatomy at Middlesex Hospital, said he made a *post-mortem* examination. The body smelt strongly of carbolic acid, the membranes of the brain were thickened, the tongue whitened, the lungs smelt strongly of carbolic acid, the stomach was intensely inflamed, also the small intestines and mucous membrane. The stomach contained a pint of dark fluid, also dark globules, which, after the application of tests, were found to be carbolic acid; and the cause of death was poisoning by carbolic acid.

The jury returned the following verdict:—"Death from poisoning by carbolic acid, taken by accident."—*Daily News*.

Suicide by Corrosive Sublimate.

On Friday, September 8, an inquest was held at the Middlesex Hospital, Charles Street, touching the death of Mr. Samuel Dutton, a smith and bellhanger, residing in Soho. Henry Alder said he had been employed by deceased. On Tuesday last he was called out of the shop into the yard, when deceased said he had taken corrosive sublimate. Witness brought some salt and water, but he would not take it. He brought him in a cab to the hospital. Dr. Lucas stated that deceased was admitted into the hospital on Tuesday, and died the same day. He was suffering great pain from an irritant poison, and was in a state of collapse. He had swallowed about 75 grains of corrosive sublimate, which was the cause of death; but he had vomited so freely that there was no reaction. The stomach was much inflamed. Verdict, "Suicide whilst of unsound mind."—*Standard*.

Case of Suicide at Leeds.

An inquest was held by Mr. Emsley, the Leeds borough coroner, on September 8, touching the death of John Marshall, aged sixty-six, a gentleman who lived with his brother-in-law, Mr. Fox, in Grafton Street. The deceased was formerly in business as a sawyer in America, where he resided for twenty years, and from which he returned about a year since. Whilst in America he had a sunstroke. This caused him to have violent pains in his head at intervals, and sometimes he expressed himself afraid that he might lose his senses. On Wednesday afternoon the pain attacked him with great severity. He went to the Stag Inn, in Camp Road, and there he was observed to be very strange in his manner. He told Mrs. Bateson, the landlady, as he was leaving the house, that he should never come back again, and, pulling out his watch, he asked her to note the hour. He went home, and his conduct being so singular, Mrs. Bateson thought it proper to follow him, and to see him in the house. She found him lying on the sofa, all trembling. Asking him what was the matter, he pointed to his throat, and he signified that he had swallowed some strychnine, a quantity of which poison still remained in a small bottle he pulled out of his pocket. He told her that he had brought the poison from America. Death took place in about half an hour, and the symptoms all pointed to strychnine poisoning. Mr. Seaton, surgeon, who was called in, stated that the bottle contained about forty grains of strychnine. The jury returned a verdict "That the deceased committed suicide whilst influenced by temporary insanity."

[*** It is worthy of note that in this case, as in many others that have been published, the poison used by a suicide had been in his possession for a considerable time, and had been obtained from a source extraneous to that of a retail purchase from a chemist.—Ed. Pharm. Journ.]

The Weights and Measures Act.

On Monday the magistrates of the city of Canterbury gave rather an important decision under this Act. The Chatham Paper Mills Company, who have a manufactory in Canterbury for the preparation of rags, were summoned by the local inspector for having an unjust weighing machine. The fact of the machine being incorrect was not so much questioned as the right of the inspector to enter the premises; it being argued, on the latter head, that he had no power under the Act to test weights and measures other than those which were used for ascertaining the measure or weight of goods exposed for sale. The company's premises were used as a warehouse simply, and it was contended that the inspector had no more right to enter, in order to test the weights, than he had to make visits to the residences of private persons, where weights, etc. were probably kept to test the quantities of goods brought into the house. The Bench held the objection to be valid, and dismissed the information.—*Times*.

Review.

Storia della Farmacia e dei Farmacisti, appò in Principali Popoli del Mondo. Per Federigo Kernot. Naples. 1871.

The Italians have shown during the last twenty years so many sterling qualities in their struggle to regain their former position among the nations, that every additional proof of their vigour and activity in whatever direction it may show itself must be heartily welcomed, and we therefore gladly bear witness to the intrinsic value of Mr. Kernot's work both as a national and as a pharmaceutical achievement. The author has studied his subject well, and he has the gift of interesting, even fascinating writing; he is an enthusiastic pharmacist (the title-page shows a picture of his shop-window), but his enthusiasm is of a lofty and high-minded character; the sentiment of an ancient pharmaceutical obligation at the beginning of the first chapter vibrates through the whole book, "Je jure et promets avant Dieu . . . de donner aide et secours indifféremment à tous ceux qui m'emploieraient, et finalement de ne tenir aucune mauvaise et vieille drogue dans ma boutique."

In many countries where, as in England, the pharmacist is more of a tradesman, there is, as with us, an earnest and hopeful endeavour to raise him to the more dignified position of a professional man, which he has long obtained in Germany and elsewhere; and we must be very much mistaken unless this book will greatly assist in elevating the Italian pharmacist in his social and professional position.

The book is divided into two parts, viz. ancient and modern pharmacy. The first part, and we intend to speak to-day of this only, leaving the second for future consideration, consists of seven chapters, most of which are very interesting, while others do not bring many new facts; and this is not to be wondered at, if we consider that it is the first Italian book ever written on pharmacy proper.

In tracing back the history of pharmacy Mr. Kernot has no hesitation in beginning with the beginning. He goes back to Adam, because with his fall human nature became heir to all bodily infirmities, and remedies were empirically employed long before the science of curing had been born. Many quotations from Scripture are given in proof of the application of pharmaceutical remedies.

In these warlike times it will be interesting to learn that the first ambulance was established under the walls of Troy by Æsculapius' two sons, Mæonius and Podalirius, who had collected all medicaments required by the warriors.

The first shop is mentioned by Aristophanes 1160 B.C. in one of his plays, where a certain Lamachus, with a broken leg, and another roisterer with a broken head are taken to Doctor Pittalo's iatrion, which meant a room filled with plasters and other preparations for internal and external application.

Passing through the most ancient times, the author gets to the early history of pharmacy in France, where we meet with a curious obligation the pharmacists of the thirteenth century had to take; it consists of a confession to live and to die in the true faith, to love, honour and respect his parents and former masters, and a long list of special items, clearly illustrating the pharmacist's position to the general public and to the medical profession.

The first pharmaceutical corporation was established in Bruges, 1297; at the commencement of the fourteenth century they had a large meeting room, a chapel, a corporation seal, and bye-laws; they enjoyed the exclusive privilege of vending medicines, and members of high and distinguished families were proud to join them and hold office.

The first regular shop was opened at Paris in 1336, at London in 1345, and in Nuremberg in 1404. In 1497 the first law referring to the inspection of pharmacies was published.

It is surprising to find how very early proper regulation and inspection was recognized in France; a law, dated 1352, prescribed that the head of the pharmaceutical corporation, assisted by two masters in medicine, chosen by the dean of the medical faculty, and by two pharmacists appointed by the Provost, should twice a year inspect every business in Paris and suburbs, viz. at Easter and at All Saints; and this inspection was looked upon as so important, that the members elected for the business had to swear to be guided in this work only by the spirit of the regulation, without favour or malice to any one, and to act for the public good and the welfare of human nature.

The pharmacists themselves had also to take solemn oath as to the manner in which they carried on their business, the concluding sentence of which was that they will do nothing against justice or morality of the craft, be it from avidity of gain, from particular malice, or any other cause whatever.

The author not unjustly observes that the laws passed from time to time in respect to a certain branch of industry, often give the best idea of its development, and for this reason he has collected all the laws respecting French pharmacy from 1312 to 1777, the year of the foundation of the College of Pharmacy, and thence down to the most recent times, and many stringent and salutary regulations are there to be found.

With true southern liveliness the author describes the invention of the enema apparatus, which he looks upon as an epoch in pharmacy as important as the discovery of America in the history of human civilization. The glory of the invention of this instrument, so beneficial to suffering mankind, belongs to an Italian, Gatenaria, whose name ought to find a modest place together with Columbus, Galileo, Gioja and other eminent and illustrious Italians; he was compatriot of Columbus and Professor at Pavia, where he died in 1496, after having spent several years in the perfection of his instrument.

The enema apparatus may be justly named the queen of the world, as it has reigned without a rival for 300 years over the whole Continent, besides Brazil and America. The enema came into use soon after the invention of the apparatus itself. Bouvard, physician to Louis XIII., applied 220 enemas to this monarch in the course of six months; in the first years of Louis XIV., it became the fashion of the day; ladies took three or four a day to keep a fresh complexion and the dandies used as many for a white skin. Enemas were perfumed with orange, angelica, bergamot and roses; and Mr. Kernot exclaims enthusiastically, "Oh! se tornasse questa moda" (oh, that this fashion would return!)

The medical profession first hailed the invention with delight, but soon found the application *infra dig.*, and handed it over to the pharmacist; but shameful invectives, sarcasms and epigrams hurled at those who exercised the humble duty of applying the apparatus, made them at last resign it to barbers and hospital attendants.

As a specimen of these epigrams the author gives the epitaph on a tombstone of an ancient pharmacist:—

> "Ci gît qui pour un quart d'écu
> S'agenouillait devant un cu."

But to return to some of the ancient French laws. A decree of Parliament, dated August 3rd, 1536, ordered, under a fine of 100 marks silver, of corporeal punishment and eventually the gallows, strict adhesion to certain rules laid down 1514; these rules referred to proper inspection, to the preparation of remedies and their *quid pro quo*. This expression, for the first time officially used in this decree, had the honour of passing into all languages, and its original meaning was as follows:—A great many substances employed by the pharmacists came from foreign parts, and, as it often was difficult or impossible to obtain them, it became necessary to substitute others somewhat similar in their action; hence *qui pro quo*, *quod* or *quale pro quo*, originally meant the substitution of a drug easily obtainable in place of another scarce one.

The same decree ordained that two medical men and four pharmacists, good, honourable, well-established and experienced men, after having taken a legal and binding oath, should twice a year, during Lent and in August, inspect the drugs, which the pharmacists were bound to expose on a table from six in the morning to six at night, and within twenty-four hours after their arrival in Paris; and if the drugs were found to be spurious, or of inferior quality, they were to be put in a bag, taken before the Provost, and then to be burnt before the offender's house. The inspectors had on the same day to send to the police a report of their examination, and to practically demonstrate before the provost the efficacy or otherwise of the drug.

The interesting account of the French laws is followed by a history of embalming, and by a curious record of *poets* who sang and wrote the praise of pharmacy, of whom we can notice only one or two English writers. In 1665 a remarkable work was published by Dr. Steward, entitled 'The Urinal of Physic,' with an appendix on the abuses of medical men and pharmacists.

During the reign of William III. Samuel Garth published a satirical epic named 'The Dispensary.' He had opened in York a business under the name of dispensary, in which he supplied the poorer classes at very low prices; this gave rise to so much animosity against him on the part of the other pharmacists who had combined against him, that he finally was obliged to close his business, when he revenged himself with the poem.

In 1569 a book was published in London under the title 'The Secrets of Alexander,' coming not exactly under the description of pharmaceutical poetry, but containing many excellent remedies for various diseases, wounds and accidents; prescriptions to preserve eternal youth and to stave off old age. A very simple cure of the plague is as follows:—"Procure a branch of the rue, of the nut and of the fig-tree; eat them all three, and you will be cured." Among much nonsense and prejudice of the times is found much good advice. There are excellent receipts for perfumed oils and waters, which might be followed with advantage at the present time.

The second part, dealing with the state of pharmacy in different countries, must form the subject of a separate article, as the accounts of pharmacy in China and other foreign countries will, we believe, be read with great interest.

The Examinations, North British Branch.

Sir,—Will you allow me to ask Mr. Mackay on what grounds the Board of Examiners in Edinburgh, at the examination on the 18th July, 1871, placed before the candidates for the Preliminary precisely the same questions that had been circulated throughout the country by the London Board at the general examination in the preceding January and April? The questions in Latin, Arithmetic and English, to which I refer, were also published in the Journals of Jan. 21 and April 22, 1871.

"One who has Passed."

The Council of the North British Branch of the Pharmaceutical Society.

Sir,—Had I anticipated that my remarks upon the conduct and working of this Council were to enter the breasts of Mr. Mackay and some of his friends with such bitterness, I certainly would have hesitated before I entered on this discussion. As it is, however, I cannot see that there is any cause for regret being expressed or exhibited in regard to the matter, either by one party or another. Burns, in one of his thoughtful moments exclaims, "Oh! that we could see oursel's as others see us," and I think our Edinburgh friends might do worse than endeavour to have a little of the insight the poet so much desired. They seem to think that because the late Mr. Jacob Bell decreed that a self-elected council should be established at Edinburgh, and that because they have gone on undisturbed in their own quiet way for twenty years, this state of matters should continue to exist, and, like Tennyson's 'Brook,' "Flow on for ever."

It may have been all very well in those early days when the members of the Society in Scotland were a mere handful, and mostly confined to the Scottish capital, and when few took any active interest in the Society; but now that its membership is extending far and wide, and these taking a much deeper interest in its affairs, I maintain that it is time some steps were taken to extend the influence and usefulness of the "North British Branch;" and I am glad at the acknowledgment Mr. Mackay has made, that some such scheme is lurking in the brain of some of the members of Council. I only hope that it will not be long until we have Mr. Mackay's fair promises of amendment realized, and this scheme before us for discussion.

I do not intend, at this time, to enter into the details of Mr. Mackay's elaborate and eloquent epistle. I observe others have taken up the matter, and I shall leave it to them. I may, however, say, that my object in opening up the question is as much for the common good of the Society as any of Mr. Mackay's past efforts have been; and I repeat, that I have not done so out of jealousy, or desire to accuse unwittingly, or even to lower in the estimation of the members the great efforts Mr. Mackay and his friends have made in past years to raise and uphold the status of the Society. I am confident of all this, and I believe I would be wanting altogether in that generous nature which characterizes our race, did I not acknowledge it. At the same time, I hold that since the passing of the Act in 1868,—and I say it without fear of contradiction,—the representatives of this Council have not acted towards the Scottish pharmacists in the manner they should have done, from their position and standing. In conclusion, Mr. Mackay accuses me of misapprehension. I find, however, I am not alone in this; the idea of having Examining Boards in all the large towns is an old theory, and which, to my mind, has been exploded long ago, I therefore could not argue for anything of the kind.

A word to Mr. Kinninmont. He has endeavoured to blow hot and cold in one breath; he is a man of peace, however, and abhors warfare, unless when there is real necessity for it; and being for many years back a member of this Council, although he has seldom taken an active part in its proceedings, he possibly considers there is no need for the present discussion.

J. M. Fairlie.

St. George's Cross, Glasgow, September 12th, 1871.

Prescription Writing.

Sir,—In the very serious case of Mr. Wall, whose death was caused by an overdose of morphia, it is stated in the medical evidence that there was great carelessness undoubtedly on the part of the chemist. Another doctor said that, although he should not have made the blunder, yet it was quite possible that a person might have made a worse mistake, as the writing of the prescription was very bad. These remarks induce me to ask the question, why do medical men write so carelessly and illegibly? The dispensers are at a loss frequently to make their prescriptions out satisfactorily. In my experience, extending over forty years and upwards, I have had prescriptions brought to me to prepare so difficult to decipher, that not even all the doctors in the town could make them out, and they have left me to use my own discretion as to their preparation. It will be admitted by those engaged in this onerous duty that we are often placed in this position, whereas there ought not to exist the slightest doubt in such matters.

I hope these remarks may meet the eyes of those they are intended for.

September 12th. M. P. S.

Homœopathic Chemists.

Sir—May I be allowed to protest in the pages of the Pharmaceutical Journal against the late judgment of the Council in the case of Messrs. Gould and Wyborne? I think that the gentlemen who voted against Mr. Williams' motion would have done better to have remembered the maxim, "In necessariis unitas, in dubiis libertas, in omnibus charitas."

When gentlemen go up for the examinations, they are never asked whether they are homœopaths or no, but are simply passed according to their merit, and it is very hard on homœopathic chemists, who were in business three years before the Act, if they be debarred from the same privileges as their allopathic *confrères*.

As to Mr. Groves' argument, "the booksellers and others," agents for homœopathic medicines, do not, as far as I am aware, dispense doctors' prescriptions, but simply sell the phials of medicine ready done up, and therefore would not be eligible under the Act. Also Mr. Groves, in thus despising booksellers, apparently forgets the many allopathic chemists in the country who are Italian warehousemen.

H. Edmonds.

20, *Bishop's Road, September 12th*, 1871.

Sir,—I fear that Mr. Groves and those members of the Council who supported his opposition to the admission of Messrs. Gould and Wyborn as members of the Society, on the ground of their being homœopathic chemists, will be horrified to learn that their laudable endeavours to preserve the purity of the Society, and to prevent its contamination by the homœopathic heresy, have been vain and fruitless, and that we are already infected by the plague.

I know one homœopathic chemist who is not merely M.P.S., but is also pharmaceutical chemist; and not only so, but having allowed his subscription to lapse for several years, paid up his arrears in 1868, and was restored to membership by a vote of the Council. Now, whether it was that the Council at that time was more liberally disposed, or that his heretical opinions were not known, or that Mr. Groves was not there to protect the purity of the Society, or that his having taken the disease after arriving at years of discretion, affected the decision, I cannot say, but he was reinstated, and continues to be a member, no one molesting him or questioning his right to be so.

Without, however, entering into the question of right, I believe that as a matter of policy Mr. Groves and his friends have made a grave mistake in refusing to elect Messrs. Gould and Wyborn, for it should be remembered that if homœopathy be true, it will succeed in spite of all the opposition they can offer; and if not true, it was very unwise to give it a fictitious importance by refusing two of its professors admission to the Society, and thus, to a certain extent, making martyrs of them.

The discussion shows also in a remarkable way how men's prejudices influence their judgment. In the poison regulation case, "may" is held to mean "must;" whilst in the present instance, "may," which is as nearly "shall" as possible, is interpreted as meaning "you may do just as you please." Surely if the former is a positive duty, the latter is equally so.

Besides, when we remember that in future no one can legally practise as a homœopathic chemist without passing the Society's examinations, it does seem somewhat absurd to tell a man that if he does certain things he may be elected a member or associate of the Society, as the case may be, and then refuse to admit him when he offers himself for election.

263, *Cheetham Hill, Manchester,* W. WILKINSON.
September 12*th*, 1871.

Sir,—At the meeting of the Council held on the 6th inst., Mr. Edwards asked if there were any homœopathic chemists members of the Society.

With your permission, I will answer that question, and offer a few remarks on the subject which led to this question being put.

There are several homœopathic chemists who style themselves "Member of the Pharmaceutical Society."

Mr. J. M. Rendall, of Exeter, is one of them.

Also, some of their assistants are members of the Society.

It is, therefore, more than probable that the proposal will again be made to admit homœopathic chemists who are registered chemists and druggists to membership with the Society.

The observations which were made respecting the scientific education of homœopathic chemists are quite just; for some of them have had no scientific (pharmaceutical) education whatever, but others have had an excellent education, and in scientific attainments will bear comparison with some of the ablest members of your Society.

Unfortunately, for the status of homœopathic chemists, as such, they have (hitherto) consented to be ignored by the new and amended Pharmacy Acts, that they might avoid being subject to the regulations which are made obligatory upon chemists and druggists, pharmaceutical chemists, and members of the Pharmaceutical Society. Nevertheless, being alarmed lest future parliaments should look more closely into their assumed claim to exemption from parliamentary control, they have established a defence society, dignified by the name of "The Homœopathic Pharmaceutical Society of Great Britain." Funds have been provided for defensive and protective purposes, and an appeal was made to all those who styled themselves homœopathic chemists. The inevitable result of this appeal was, that the badly educated and incompetent gladly paid a subscription which entitled them to affix to their names "Member and one of the Founders of the Homœopathic Pharmaceutical Society of Great Britain." Some of the homœopathic chemists, disgusted with this result, have stood aloof from the new Society, and have been registered as "Chemists and Druggists." Also, they propose sending their apprentices before the Board of the Pharmaceutical Society for examination, with a view to their obtaining the diploma of the Society.

I have had twenty years' acquaintance with homœopathic pharmacy, and my experience justifies my dissenting from the remarks made by Mr. Hills. Homœopathic chemists prepare tinctures of many of the indigenous plants, and these are supplied to German and American homœopathic chemists, who in exchange supply tinctures (of plants indigenous to those countries) to the English chemists; they also employ pure chemicals and mineral products in the preparation of their remedies; consequently they are obliged to retain and employ their knowledge of botany and chemistry in their pharmacies.

Again, membership with your Society will prove helpful to the homœopathic chemist, for it will remove him from his present false relationship to the medical profession and to the public.

It is not for the public interest, but altogether prejudicial to it, that the homœopathic chemist should be relieved from the performance of the obligations which have been imposed upon members of the Pharmaceutical Society. He keeps in stock crude drugs and chemicals, including all the scheduled poisons, and occasionally dispenses prescriptions which contain poisonous quantities.

This state of things cannot continue much longer, and a timely recognition by the Pharmaceutical Society of the homœopathic fraternity will tend to separate the wheat from the chaff, and prevent the separation of interests which is altogether unnecessary and injurious.

JOHN PARTON BERRY, M.R.C.V.S., and
Registered Chemist and Druggist.

THE CHIPPENHAM CASE.

Sir,—Allow me through the medium of your widely circulating Journal to say a few words in reference to the late sad case of death which has just taken place at Chippenham.

I do it to compare the relative positions occupied by the chemist and doctor after either has been arraigned before a coroner's jury to account either for an accident on the part of the former, or for ill-judged treatment on the latter side.

We see as recently as the last fortnight where a chemist in case of having administered an overdose of morphia in error has had the ill-luck (for I can term it nothing else) to be pounced upon by the Home Secretary, even after the jury had expressed a somewhat sympathetic verdict, and when he (the chemist) had laboured under the difficulty of having to decipher a badly written prescription. The case referred to at Chippenham, however, is very different in respect to the treatment by the authorities of the person charged. Here we have a child to whose head a solution of bichloride of mercury, of the strength of 10 grains to the drachm, or 80 grains to the ounce, has been applied, and who in the course of two or three days sinks from the result.

I should very much like to ask what punishment the chemist might expect to receive from the "authorities" if he should be ignorant enough to make use of such an "outrageously strong" application? Who amongst the trade of chemists, whether apprentice of twelve months' standing or assistant, would think for one moment of using a thing so powerful and caustic to the head of a child?

Never in my experience was an instance more glaring of the injustice of the law in the comparative treatment of the two persons accused.

Is not this a case, amongst unfortunately too many others, which should teach the medical profession generally to show a kinder feeling to those who like themselves follow an anxious and responsible calling? M. P. S.

Sept. 10*th*.

PILLS, ONE PENNY A DOZEN.

Sir,—Your correspondent, N. O. P., complains of the low price charged for dispensing in his neighbourhood; he has reason to congratulate himself they are no worse. The other day a man brought a receipt for making eight dozen pills, and asked how much I would charge to make them up. I said 2*s*. 6*d*., which I considered a moderate price, being less than 4*d*. a dozen. He appeared to be very much astonished and said, "Why, I got them made up at ——, in the Essex Road, for 8*d*. He charged me 2*d*. for each of the articles (the pills were composed of three ingredients), and 2*d*. for making them." Of course I declined working so much below ordinary labourer's wages, and he declined paying more than 8*d*. for them, and so the matter ended. On a par with this we have a man in the Kingsland Road, in an apparently respectable shop, who sells patent medicines at cost price, and many other articles at what the drapers would call "a ridiculous low price." When will druggists learn to study their own interest, instead of cutting their own throats and injuring their neighbours and the trade generally?

Islington, September 4*th*, 1871. FAIR PROFIT.

THE TINCTURE PRESS.

Sir,—In the excellent tincture press of Mr. Staples, of which an account and engraving are given in your last issue, there is one little practical difficulty suggests itself to me, and which no doubt Mr. Staples can easily solve. The cylinder, it appears, stands in the spouted basin, and the basin has no outlet for the expressed juice without unscrewing the press, and by that means emptying it. The ingredients stand in the expressed juice the whole time they are under pressure, without being allowed to drain off. I should be glad to know if there is any difficulty to be experienced on that score before having one made.

I should also like to know where Mr. Staples obtained his tinned iron cylinders pierced as he describes.

320, *Roman Road, Bow, Sept.* 13*th*. S. D.

ERRATUM.—In the article on "Pharmacy in Spain" last week, the words "of the monk" were omitted from the 18th line from the bottom, p. 183, before "of Monte Cassino."

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. Mackay, Mr. J. J. Macaulay, Mr. Hustwick, Mr. J. Garrett, Mr. G. Pattison, Mr. S. Dean, Mr. Hartley.

"G. P. E." is referred to the notice concerning anonymous correspondents.

DETERMINATION OF GLACIAL ACETIC ACID.

BY FR. RÜDORFF.

The volumetric estimation of acetic acid by means of a standard solution of caustic soda cannot claim very great accuracy, because the change in colour of litmus is not sufficiently marked. Mr. Rüdorff has therefore proposed a new method, readily executed and very accurate, which consists in determining the solidifying-point of the acid.

Commercial glacial acetic acid is never free from water, the solidifying-point of various samples ranging from 7° C. to + 14° C. In order to obtain some perfectly anhydrous, a quantity of the commercial acid was placed in a cold place, until about three-fourths of it had solidified; the liquid part was separated, and the solid portion was remelted, cooled and solidified. The liquid was again separated, and this operation repeated until at last a constant solidifying-point was obtained; this point gradually rose after each separation of liquid, as shown in the following observations, made with a sample of about two pounds:—12°·5, 15°·1, 16°·1, 16°·4, 16°·65, 16°·7, 16°·7, 16°·7 C.

It is advisable to leave the liquid, in which some solid acid separated overnight, in a room the temperature of which is a few degrees below the solidifying-point of the acid; the last then separates in foliated masses, from which the liquid may easily be poured off; this liquid, of course, contains more water than the remaining solid acid.

The solidifying-point of this solid acid is 16°·7 C.; its boiling-point is 117°·8 C. With gradual cooling the temperature may be reduced to 10°, and even 8°·5, and the acid may be shaken without solidifying; but a single grain of solid acid sets the whole mass at once, the temperature rising to 16°·7 C. When melted by placing the vessel in water of about 25° C., the thermometer placed inside the acid indicates 16°·7 C. as long as a considerable quantity of solid substance remains,—proving that the melting and solidifying points are at the same temperature.

100 parts by weight of anhydrous acid were mixed with a weighed quantity of water, and the solidifying-point of the mixture was determined. It must be remembered that a mixture of two liquids does not solidify as such, but only one of them, in this instance acetic acid; while the water remains fluid. Aqueous concentrated acetic acid acts similarly to saline solutions, of which the author has shown that, on freezing, the water alone solidifies.

The proportion of acid and water would be altered if much acid solidified; it is therefore necessary to take care that only very little acid separates. This is effected by cooling the mixture to within one degree of the solidifying-point, approximately determined; after which a particle of solid acid is added, and the liquid well stirred with a delicate thermometer. Repeated experiments show a difference of not more than 0°·1 C. The following table contains the results of a series of observations, viz.:—

100 parts by weight of acid mixed with water.	100 parts of mixture containing water.	Solidifying-point. Degrees.
0·0 Water.	0·0 Water	+ 16·7 C.
0·5	0·497	16·65
1·0	0·990	14·80
1·5	1·477	14·00
2·0 Water.	1·961 Water	+ 13·25
3·0	2·912	11·95
4·0	3·846	10·50
5·0	4·761	9·40
6·0	5·660	8·20
7·0	6·542	7·10
8·0	7·407	6·25
9·0	8·257	5·30
10·0	9·090	4·30
11·0	9·910	3·60
12·0	10·774	2·70
15·0	13·043	— 0·20
18·0	15·324	2·60
21·0	17·355	5·10
24·0	19·354	7·40

The table shows that especially in concentrated acid one-tenth of a percentage of water may be accurately determined.

Several other substances act like water in reducing the solidifying-point of acetic acid; for instance, sulphuric acid, alcohol and several salts soluble in the acid. A mixture of 100 parts of acetic acid and 0·5 part of sulphuric acid solidifies at 16°·4 C.; 100 parts of acid and 1·8 parts of alcohol at 15°·25 C. The influence of water may be partly counteracted by sulphuric acid; thus, from a mixture of 100 parts of acid and 10 parts of water the acid separates at 4°·3 C.; an addition of 2 parts of sulphuric acid raises the point to 5°·8 C., and 20 parts of sulphuric acid added to the same mixture bring the point up to 10°·7 C.

The solidification of acetic acid takes place even in summer with absolute accuracy. The acid is cooled to about 10° or 12° C., a particle of solid acid is added, and on shaking the bottle the acid solidifies forthwith. A small quantity of solid acid is easily obtained by placing a test tube containing a few drops of liquid acid in a mixture of chloride or nitrate of ammonium and cold water.—*Wittstein's Vierteljahrsschrift für prakt. Pharm.*, 1871, p. 84.

ERGOT OF RYE.

BY DR. T. C. HERRMANN.

Although ergot of rye has been repeatedly subjected to chemical analysis, there are several questions touching its component parts which have not been fully explained, and for this reason Dr. Herrmann has chosen the subject for his inaugural dissertation.

One of the constituents of ergot which required further investigation is the fatty oil, which, though not differing from other oils in general characteristics, is peculiar so far, as according to Manassewitz, it readily saponifies with caustic soda, but not at all with caustic potash; this statement Dr. Herrmann was enabled by his investigation to distinctly contradict.

20 ounces of powdered ergot were exhausted with ether, the last separated by distillation, and the oil, which amounted to 6 ounces, subjected to analysis. It was of a brownish-yellow colour, of aromatic flavour and acrid taste, viscid, and its sp. gr. was ·9249, it was not drying.

It consisted chiefly of palmitic acid, oleic acid and glycerine, in the proportion of 22·703 per cent. palmitic acid, 69·205 oleic acid, and 8·091 glycerine; it also contains traces of acetic and butyric acid, of trimethylamin, ammonia and ergotine as colouring matter.

Manassewitz also doubted the existence of ecboline, the alkaloid first separated by Wenzell, and Dr. Herrmann also settled this point.

30 ounces of powdered ergot were for several days digested with warm water, the aqueous extract mixed with acetate of lead, and the precipitate separated by filtration, excess of lead in the filtrate was separated by carbonate of soda, which, however, did not precipitate all the lead, the liquid remaining turbid even after filtration; it was therefore slightly acidified with muriatic acid and thin dilute sulphuric acid added, which gave a clear solution; to this an excess of chloride of mercury was added, the dirty white precipitate was collected on a filter, and the alkaloid ecboline separated in the usual manner. It is soluble in water and alcohol, has a bitter taste and an alkaline reaction, and is precipitated in the following manner, viz. by chloride of mercury white, phosphoric molybdic acid yellow, tannin dirty white, biniodide of potassium reddish-brown, chloride of gold brownish, chloride of platinum orange, only after some time, and cyanide of potassium white.

The inorganic constituents of ergot were also determined afresh, and the following table gives a comparison of former analyses with Dr. Herrmann's results, viz.:—

	Engelmann.	Manassewitz.	Thielau.	Herrmann.
Potash	38·97	38·00	17·92	30·06
Soda	14·39	14·75	11·42	0·65
Lime	1·43	1·50	1·24	1·38
Magnesia	4·58	4·70	2·00	4·87
Alumina	—	—	0·29	0·58
Oxide of iron	2·00	1·80	0·70	0·86
Oxide of manganese	—	—	3·95	0·26
Oxide of copper	—	—	0·53	—
Phosphoric acid	13·24	13·25	58·66	45·12

PRESERVATION OF EGGS.

BY H. VIOLETTE.

Experiments have led Mr. Violette to the conclusion that a thin film of oil is the best means of keeping eggs for a long time.

Fresh eggs kept for three months had lost 11·40 per cent. in weight; after six months, 18·10 per cent.,—they were half empty and rotten. Eggs covered with a thin film of poppy oil had lost, after three months 2·90 per cent.; after six months only 4·51 per cent.,—they were full, of good taste and smell.

Eggs covered with linseed oil lost in three months 2·16 per cent., and in six months only 3·02 per cent.; they were full, and tasted and smelt as good as fresh eggs.—*Journ. de Pharm. et de Chim.* 1869, x. 170.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Magnesiæ Sulphas.—Made by the action of diluted sulphuric acid, either upon the calcio-magnesic carbonate, "dolomite," or upon the native magnesic carbonate, "magnesite." The latter, being now largely imported, is used very extensively.

$$MgCO_3 + H_2SO_4 = MgSO_4 + H_2O . CO_2.$$

It is also obtained in some quantity from seawater and from other sources.

[§ In minute, colourless and transparent (right) rhombic prisms. It readily dissolves in water, and the solution gives copious white precipitates with chloride of barium, and, with a mixed solution of ammonia, chloride of ammonium and phosphate of soda ($Mg''NH_4PO_4 . 6H_2O$). Its aqueous solution, at ordinary temperatures, is not precipitated by oxalate of ammonia; nor should it give a brown precipitate with chlorinated lime or soda.] Absence of sulphates of calcium, iron and manganese is thus ensured. Sulphate of magnesium is isomorphous with sulphate of zinc and by appearance indistinguishable from it. The zinc salt, however, gives a white precipitate with sulphydrate of ammonium and with ferrocyanide of potassium, whilst magnesium sulphate gives none. The precipitate, also, which liquor potassæ produces with sulphate of zinc, is soluble in excess, but not so with sulphate of magnesium.

The formula of sulphate of magnesium is—

$$MgSO_4 . 7H_2O;$$

but, as in the case of ferrous sulphate, six molecules only of the water, can be regarded as water of crystallization.

Manganesii Oxidum Nigrum.—A heavy black powder, formed by grinding the mineral, which is found native partly in a crystalline state. It is generally purified from the calcic carbonate, which the crude material generally contains, by treating with diluted hydrochloric acid.

Mixed with strong hydrochloric acid and kept cold, it forms a nearly black solution of manganic perchloride:

$$MnO_2 + 4HCl = MnCl_4 + 2H_2O.$$

On the application of heat chlorine is evolved, and a solution of manganous chloride remains.

$$MnCl_4 = MnCl_2 + Cl_2.$$

It evolves oxygen when heated to redness, leaving a residue of manganous-manganic oxide.

$$3MnO_2 = Mn_3O_4 + O_2.$$

The black manganese of commerce varies greatly in quality, and as it is extensively employed in the generation of chlorine frequent analyses of it have to be made. The best method is Bunsen's. In short, it consists simply in distilling a weighed quantity of the sample with excess of pure hydrochloric acid in a small flask, the neck of which is connected, gas-tight, with a U tube, containing solution of iodide of potassium. The chlorine evolved from the flask, as it passes through the iodide of potassium, liberates an equivalent quantity of iodine, the amount of which is rapidly and accurately determined by means of the volumetric solution of hyposulphite of sodium.

PHOSPHORUS. P = 31.—[§ A non-metallic element obtained from bones.]

Bone ash is digested with sulphuric acid, by which calcic sulphate and a soluble superphosphate are obtained.

$$Ca_3(PO_4)_2 + 2H_2SO_4 = CaH_4(PO_4)_2 + 2CaSO_4.$$

The acid solution is boiled down till it sets into a paste. The acid superphosphate then loses water and leaves a residue consisting chiefly of calcic metaphosphate.

$$CaH_4(PO_4)_2 - 2H_2O = Ca(PO_3)_2.$$

This salt, mixed with charcoal and distilled in earthen retorts, gives phosphorus, which passes over and is received in water, carbonic oxide gas and tricalcic phosphate, which remains behind.

$$3Ca(PO_3)_2 + 10C = Ca_3(PO_4)_2 + 10CO + P_4.$$

The crude phosphorus is coloured brown from the presence of oxide and other impurities. It is purified by melting under water, and stirring up with a mixture of sulphuric acid and chromate of potassium. The pure phosphorus settles as a colourless oily layer. Commercial phosphorus is either in sticks or cakes.

[§ A semi-transparent colourless wax-like solid, which emits white vapours when exposed to the air. Specific gravity 1·77. It is soft and flexible at common temperatures, melts at 110°, ignites in the air at a temperature a little above its melting-point, burning with a luminous flame, and producing dense white fumes.] Exposed to light it becomes covered with a white or sometimes a reddish crust, which is one of the numerous allotropic forms of phosphorus.

[§ Insoluble in water, but soluble in ether and in boiling oil of turpentine.] Also freely in bisulphide of carbon, by the evaporation of which solution phosphorus may be obtained in crystals.

For dispensing purposes phosphorus is sometimes required to be granulated. This is easily effected by placing the requisite quantity in a stoppered bottle with a little proof spirit, immersing the bottle in warm water till the phosphorus is melted, and then shaking briskly till cold.

Red or Amorphous Phosphorus.—The most important of the allotropic modifications of phosphorus is a red pulverulent substance obtained by heating common phosphorus in vessels from which the air is excluded to a point about 100° F. below that at which phosphorus boils. It is purified by dissolving out the unchanged phosphorus by bisulphide of carbon. It is now used, to a certain extent, in the manufacture of matches. It differs from the common kind in being quite insoluble in ether, benzol, bisulphide of carbon, etc., and in being far less easily inflammable. When volatilized it changes back again into common phosphorus.

Common phosphorus is very poisonous; red phosphorus is stated not to be so, though probably this statement refers to the fact that it emits no vapour at ordinary temperatures as the common kind does, and, therefore, that workpeople do not suffer as in the employment of the ordinary kind.

The oxides and chlorides of phosphorus are formulated thus—

Phosphorous Anhydride . . .	P_2O_3
Phosphoric Anhydride	P_2O_5
Phosphorous Chloride	PCl_3
Phosphoric Chloride	PCl_5
Phosphoric Oxychloride	$POCl_3$

There are, therefore, two classes of phosphorus compounds in which P is trivalent and quinquevalent respectively.

INQUIRIES RELATING TO PHARMACOLOGY AND ECONOMIC BOTANY.*

BY DANIEL HANBURY, F.R.S.,

AND PROFESSOR OLIVER, F.R.S.

From the *Admiralty Manual of Scientific Inquiry.*

INDIA, SIAM, AND THE INDIAN ARCHIPELAGO—*continued.*

SALEP.—The tubers of several species of *Orchis* and *Eulophia* are collected and sold in India under the name of Salep. It is desirable to ascertain what species of Orchidaceous plants furnish this substance, especially in the Himalayas and in Cashmere. What is the plant which affords the drug called *Badshah Saleb*, or Royal Salep? Where is it produced, and for what purpose is it valued? It has been exported to England from Bombay.

MANNA.—It has for many years been asserted that a kind of manna is produced in the East on a species of Tamarisk. It requires to be determined whether any oriental Tamarisk yields a saccharine substance of the nature of manna, and whether it is collected, and where?

HEMP.—A very rough but tenacious hemp is produced in Northern India, at Kangra, and elsewhere, and bears the name of "*Kangra hemp*" or "*Himalayan hemp.*" Is this the produce of *Cannabis sativa*, of which there is some doubt?

TANYIN.—What is the source of the "*Tanyin fruit*" of the Burmese trade lists, and what its uses?

MOCHARAS.—This brown astringent substance, which is found in the bazaars of India, is said to be partly derived from *Salmalia Malabarica*, part is said to be an exudation from the trunk of the Areca palm (*Areca catechu*). It would be well to ascertain if any astringent substance is exuded, or whether any galls are formed, as some suggest, on *Areca catechu*. The source or sources of the *Mocharas* should be determined.

RAJAH-CANES, exported from Borneo. The species of palm yielding these is unknown.

What tree affords the so-called *Amboyna* or *Kyabocca* wood?

GUTTA-PERCHA is, even up to the present day, little known. It is said to be yielded by several plants, such as species of *Isonandra, Chrysophyllum, Sideroxylon* and others. Attention should be paid to the vernacular names, such as *Gutta-percha, Ugiato putih, Kotian, Tuban* or *Taban*, etc. Abundant and carefully preserved wet and dry specimens of the leaves, flowers, and fruits of the different kinds, the products of the same individuals from which the dried specimens are obtained, are greatly needed.

CAOUTCHOUC, OR INDIA-RUBBER.—In the Malayan Archipelago there are many trees which yield Caoutchouc. *Urceola elastica* is the source of the Borneo india-rubber.

What trees produce the so-called Singapore rubber, and the Java, Sumatra, and Siam kinds? Are they species of *Ficus?*

* Information relating to any of the subjects here referred to may be addressed to Mr. Hanbury, Clapham Common, near London, or to Professor Oliver, Royal Gardens, Kew.

In Assam *Ficus elastica* is the chief, if not the only source of india-rubber. But *Ficus laccifera* may also yield it. Is any india-rubber collected from the latter, and is it kept separate or mixed with that of *F. elastica?* Specimens of each, accompanied by good dried specimens, would be valuable. Are there no other trees capable of yielding india-rubber in quantity? *Willughbeia edulis*, the "*Luti-am*" of Chittagong and Silhet, is said by Roxburgh to yield good india-rubber. Specimens of the india-rubber, and also carefully-prepared and abundant specimens of the leaves, flowers, and fruit, both dried and in spirit, are much needed.

China, Cochin China, and the Philippines.

Rhubarb.—The true source of the rhubarb produced in the western provinces of China and the adjacent regions is still unascertained. It is desirable to obtain living roots or seeds of the plants, as well as a full account of the collecting and drying of this well-known drug.

Camphor.—That of commerce is obtained from Formosa and Japan. Is any produced in China, and where? The Camphor Laurel (*Cinnamomum Camphora*, Nees), is well known to flourish in many localities of the central provinces.

What is the camphor said to be obtained from a species of *Artemisia* (wormwood) called *Ngai?* A few pounds of it are desired.

China Root is exported to Europe from Canton. The plant is said to grow in the provinces of Honan, Kwangtung, and Kwangsi. Good specimens of it are desired.

Root called *Green Putchuk Pă-chih*, of which large quantities are exported from Ningpo. The plant is an *Aristolochia:* to determine the species, pressed and dried specimens with roots would be acceptable.

Cassia Bark.—Specimens are much desired of the tree which affords this bark in the south of China. Botanical specimens should in all instances include good samples of the bark, young and old, obtained from the same tree.

Cassia Buds.—These are the immature fruits of a *Cinnamomum*, supposed to be that affording the Chinese Cassia bark.

Bamboo.—Specimens in flower of a bamboo, affording the broad leaves which are pinned together by the Chinese to line tea-chests, are required to determine the species.

Star Anise.—Information should be collected by an eye-witness as to the production in Southern China of this spice. It is said to be brought to the Canton market by the Fokien junks. Botanical specimens of the tree, and full particulars regarding the collection of the fruits, are desirable.

Chinese Oil of Peppermint (so-called) is said to be distilled at Canton. Pressed and dried botanical specimens of the plant *seen* to be used should be sent to England for the determination of the name.

Cardamoms.—What is the origin of the cardamom called by the Chinese *Yang-chun-sha*, the *Hairy China Cardamom* of pharmacologists? It is said to be produced in the province of Kwang-tung, and it may be a native of Cochin China.

Nothing is known of the origin of the scitamineous fruit to which the name *Large Round China Cardamom* has been given, and which is known to the Chinese as *Tsaou-kow*. The same remark applies to the *Bitter-seeded Cardamom*, *Yih-che-tsze*, and *Ovoid China Cardamom*, *Tsaou-kwo* or *Quâ-leu;* it is probable that all of them are productions of the south of China, or of Cochin China.

St. Ignatius' Beans, called in the Philippines *Coyacoy*, or *Pepita de Catbalogan*. The plant, said to be a climbing shrub, to which the name *Ignatia amara* was given by the younger Linnæus, is a species of *Strychnos*, probably unknown to modern botanists. It is believed to grow in Bohol and Çebu, islands of the Bisaya group of the Philippines. As it is one of great interest, no opportunity should be lost for procuring abundant flowering specimens, as well as the entire fruits, both dried and preserved in alcohol, and some considerable pieces of the stem with the bark attached.

Elemi.—This resin is abundantly produced in the forests of the Philippines, where it often assists in giving a cheerful blaze to the fire of the traveller. It is also exported from Manilla as a drug. The tree that affords it is probably a *Canarium*, but it is desirable to have complete specimens, including flowers and mature fruits in alcohol, in order to ascertain the species with exactness.

Mexico, the West Indies, Central and South America.

Mexican Elemi, known in Mexico as *Copal*, is yielded by *Elaphrium elemiferum*, Royle, a tree growing near Oaxaca, good botanical specimens of which are much desired.

Sarsaparilla.—The species of *Smilax*, the roots of which constitute the various sorts of sarsaparilla found in commerce, are very imperfectly known. Good botanical specimens, comprising flowers, fruits and leaves, and accompanied by the stem and roots, should be carefully preserved, and transmitted to England for determination. The so-called *Jamaica Sarsaparilla* grows near the Chiriqui Lagoon, in the state of Costa Rica, and a species very similar, if not identical with it, at Bajorque, on the Rio Magdalena, New Granada. Other sorts of sarsaparilla are produced in Mexico, Guatemala, Honduras, Brazil, etc.

Cinnamon of Ecuador.—This bark, which resembles the cinnamon of Ceylon, is produced by a noble tree growing in the province of Canelos. Specimens of it, including flowers and the large fruits preserved in alcohol, are much desired. The calyx of the fruit is used as a spice, under the name of *Ishpingo*.

Balsam of Copaiva is imported from several parts of Brazil; it varies somewhat in properties, and is the produce of several species of the genus *Copaifera*. It is desirable to obtain the balsam of each species, with a specimen in flower and leaf, and, if possible, in fruit, of the tree affording it, and the name of the district where the tree grows, and its native appellation there.

Woods.—Lignum nephriticum.—This rare wood, noticed by some of the earliest explorers of America, is a production of Mexico. To what tree is it to be referred? Its infusion is remarkable for having the blue tint seen in a solution of quinine.

Satin-wood of the West Indies.—Specimens in flower and fruit, with the wood, are requested. The origin of the *Coca* or *Cocus-wood* of the West Indies, is also uncertain. Specimens in flower of any tree affording the lancewoods of commerce in the West Indies or Central America are needed for the determination of the species.

King-wood, Maracaybo-wood and Mustaiba-wood, all imported from Brazil, and Nicaragua-wood from Central America, are of unknown botanical origin.

The Rose-woods of Brazil.—There is still some doubt as to the trees which yield the different varieties of this timber.

Ipecacuanha.—What is the plant which furnishes the *large Ipecacuanha root* of New Granada?

Pareira Brava.—The plant affording the inert woody stems which constitute the *Pareira Brava* of commerce, and which are exported to Europe from Rio de Janeiro, has not been ascertained, neither is the locality in which it grows accurately known. The subject is deserving of investigation.

Cinchona Bark.—In addition to the bark of *Cinchona Tucujensis*, shipped at Puerto Cabello in Venezuela, there are others less known botanically which are brought from the same port. Some of these barks appear to be derived from varieties of *Cinchona cordifolia*, while others seem to belong to what is called *Quinquina* rose d'Ocaña. It would be interesting to have authentic specimens of the flowering and fruit-bearing branches of the trees, together with sections of the branches and trunk (the bark being *in situ*), for comparison with the species described by Karsten.

The so-called *False Cinchonas* may be distinguished, according to Dr. Weddell, by their capsules, which are generally large, and having valves which separate from the apex towards the base. The flowers are relatively large, and devoid of perfume. It would be of some interest to have authentic specimens of the barks of those trees belonging to the genus *Buena* (*Cascarilla* or *Ladenbergia*), in order to ascertain whether they contain alkaloids or not. The barks ought to be accompanied by flowering specimens. Some pounds of each bark would be required for chemical examination.

PARA RHATANY.—This root, imported from Pará in Brazil, is described in PHARMACEUTICAL JOURNAL I. (1870) 84. The plant yielding it should be ascertained, for which purpose good specimens, including *entire roots*, are requisite.

MILK OR COW TREE OF PARA.—Specimens in flower and fruit of this tree, which is called *Massaranduba*, are required for the accurate determination of the species.

CAOUTCHOUC, OR INDIA-RUBBER.—All the Central American caoutchouc is presumed to be obtained from *Castilloa elastica*, the "*Ule-ule*" tree. Are there any other species of this genus, or trees likely to be mistaken for *Castilloa elastica* sources of supply? In New Granada there is said to be a pinnate-leaved tree yielding caoutchouc—what is it?

HEVEA (SIPHONIA) BRAZILIENSIS is the chief source of Para india-rubber, but other species yield it, as *H. lutea*, *H. discolor*, *H. paucifolia* and *H. rigidifolia*. It would be exceedingly desirable to know the relative yield of these several trees, and to obtain good specimens of them.

In Pernambuco and Ceara there is much good india-rubber said to be the produce of *Hancornia speciosa*, the "Mangaba" of the Brazilians. Reliable specimens and information are desired.

In British and French Guiana caoutchouc trees exist, good specimens of which, with their several products, should be collected.

IODIZED COTTON.

BY M. C. MÉHU.

To render easy the absorption of iodine in such a manner that it shall not be released from its combinations too rapidly, and thus to avoid the irritation resulting from the contact of a large quantity of iodine with the skin, is a problem, the solution of which has been sought in various ways. This want has been felt principally in external applications, where the action of the medicament requires to be continued during a length of time. Even before iodine was discovered, burnt sponge was used as a remedy for goitre, it giving off slowly some traces of iodine, when placed in contact with the skin.

Certain compounds of iodine, such as iodide of ammonium and iodide of calcium, when exposed to the air, part slowly with their iodine under the influence of the oxygen of the atmosphere, but they are little used. The author, however, considers the iodide of ammonium to be a salt of great therapeutic value, he having derived much benefit from some external applications of it.

A very old mixture, called the *Collier de Morand contre le Goître*, consisted of equal parts of sal ammoniac, marine salt and burnt sponge. This powder, spread on carded cotton, and afterwards covered with muslin, was applied to the goitre in the form of a sachet or a cravat, and renewed every month. Many other sachets are known in which a mixture of sal ammoniac and iodide of potassium occur as ingredients.

Doubtless the association of sal ammoniac, or chloride of ammonium, with burnt sponge, at a time when iodine was unknown, had exclusively for its object to second the action of the burnt sponge by that of a substance possessing in a high degree analogous solvent, anti-scrofulous properties. But probably modern pharmacists, in reproducing the same association by mixing iodide of potassium with sal ammoniac, have been guided by the observation that this mixture gives off free iodine to the air exactly as if it contained chloride of potassium and iodide of ammonium.

At first, it would appear that a solution of iodine in ether, alcohol or water—in the latter case combined with iodide of potassium—would furnish an easy method for the application of iodine to the skin. But this is not the case, for these solutions are very irritating, and often cause so much pain that their application is impossible except for a short time. If they be employed in a diluted form, it is necessary to remove the bandages frequently, which also causes irritation to the skin.

A preparation of cotton with five per cent. of iodine, which the author has employed for two or three years with complete success, in cases of glandular swellings of the neck in scrofulous persons, appears to be exempt from this inconvenience. It colours the skin without irritating it, and produces a marked sensation of warmth. It parts little by little with its iodine, becomes decolorized, and requires to be renewed every two or three days, according to the locality to which it is applied. In losing its iodine it exercises all the properties of that metalloid, and when applied in the vicinity of wounds acts as a disinfectant.

The iodized cotton is prepared in the following manner:—The iodine is reduced to a very fine powder in a porcelain mortar; this operation is facilitated by the addition of a few drops of ether from time to time during the trituration. A quantity of very dry carded cotton of good quality is then selected, in proportion of at least ten times the weight of the iodine. The cotton is introduced into a large-mouthed ground-stoppered litre flask in little flocks, and with each portion of cotton is added the proportion of iodine in such a manner that it becomes incorporated in the mass of the cotton. The flask is then closed, at first incompletely, in order that the air may escape when expanded by the warmth. It is next placed in a sand-bath or other apparatus, by which it can be raised to a sufficiently high temperature. The flask should be laid horizontally, and turned on its axis from time to time, so as to render the action of the heat uniform, and to obtain a homogeneous iodized cotton. When the warm air has been driven off, the flask is closed by the glass stopper, after which it gradually becomes filled with violet vapours, and the cotton takes the colour of burnt coffee. When this result is acquired, the iodine is completely fixed in the fibre, and the operation is finished. Properly conducted, it should not occupy more than two hours.

Not more than twenty grammes of dry cotton should be put into the litre flask, in order that the mass should be permeable by the vapour of the iodine. Neither is it advisable to exceed the proportion of ten per cent. of iodine; that quantity is the extreme limit, and half that dose is generally more than sufficient.

The sand-bath may be replaced by a water-bath, if care be taken to ballast the bottle in order to keep it under water. This mode is advantageous in pharmacies when operating upon small quantities; but it is only suitable for the preparation of cotton containing not more than three per cent. of iodine.

Even when the cotton has absorbed ten per cent. of iodine it retains in a great measure its tenacity. It is properly of a brown colour, but it becomes black if the temperature be raised too high, or the action of the heat too much prolonged.

If properly prepared, the cotton, upon exposure to the air, gradually loses its iodine, decolorizes, and becomes quite white. In order to preserve it, it should be placed in large-mouthed bottles, with ground-glass stoppers. In default of a ground-glass stopper, a cork that has been steeped for some time in paraffin may be used. A cork so treated resists perfectly the vapour of iodine, which is so destructive to ordinary corks.

When cotton is placed in a concentrated solution of iodine in ether or sulphide of carbon, and exposed to the air, it pretty quickly parts with the solvent, and retains only traces of the iodine, becoming white very soon. With an alcoholic solution of iodine, the cotton retains a large proportion of the iodine. But the employment of selvents to fix the iodine yields but mediocre results, and entails the loss of a large quantity of valuable liquid out of all proportion with the results. It was thought that by dissolving the iodine in ether before mixing it with the cotton a more complete state of division would be obtained, and the operation would become more rapid. But in practice this plan was found to be defective, and it was abandoned in favour of the mode of preparation previously indicated.—*Journal de Pharmacie et de Chimie.*

THE SOURCE OF THE RADIX GALANGÆ MINORIS OF PHARMACOLOGISTS.

BY H. F. HANCE, PH.D., ETC.

Whilst it is, I believe, fully established that the "Greater Galangal" is produced by *Alpinia Galanga*, L., the plant which yields the lesser kind has hitherto remained altogether doubtful, though some writers have hazarded the opinion that it is the rhizome of *A. chinensis*, Rosc. It is now more than twelve years since my attention was first drawn to the subject by my esteemed correspondent Mr. Daniel Hanbury,] who begged me, if possible, to set the question at rest.

I have never lost sight of Mr. Hanbury's wishes; but, although the drug forms a considerable article of export from Southern China,* my want of success will not seem surprising when it is borne in mind that many vegetable products shipped from Canton come from distant parts of the empire, and pass through a number of hands before they reach those of the native merchants, and that these latter are quite incapable of comprehending the interest attaching to the solution of a doubtful scientific point, or of troubling themselves about what seem to them matters of aimless and puerile curiosity. Those who have tried know well how difficult it is to get reliable information from the natives, who will frequently invent answers rather than seem ignorant, and are especially prone to reply in the affirmative to direct or leading questions, as if they supposed the object of an inquirer was rather to obtain the confirmation of his own views than to elicit the truth.

In November, 1867, I had the opportunity of making a visit—at the invitation of, and in company with, the Commissioner of Maritime Customs at Canton—to the Island of Haenan. During this excursion, and while at anchor off Pak-shá, a fishing-village on the south coast of Kwangtung, about seventeen miles from, and rather to the east of Hoi-haú, on the north coast of Haenan, we landed, and some of the party went about six miles inland to a ruinous walled city named Hoi-on; but, being slightly indisposed, I preferred botanizing over the low hills near the coast. On their return, Mr. Sampson, who was one of the party, informed me that they had seen a large quantity of what he took for ginger (but which he described as bearing the inflorescence on the leafy stems) under cultivation; and another gentleman produced—asking if I knew what it was—some pieces of rhizome, of which quantities had been passed, exposed to the sun in shallow bamboo baskets to dry. This I immediately identified as Galangal; and as some inquiries made of a linguist who had accompanied them left no doubt that the rhizome belonged to the plant seen growing, I had the mortification of knowing that the true Galangal plant had been met with, and no specimens obtained, whilst our arrangements did not admit of further delay.

Fortunately, however, at the close of the year, another expedition to Haenan was planned; and on this occasion Mr. E. C. Taintor, an American gentleman in the service of the Imperial Customs, to whom I was indebted for the specimens of the Oaks on which the North Chinese wild silkworm is fed, respecting which I have already communicated a paper to the Society, accompanied it. Mr. Sampson took great pains to indicate to Mr. Taintor the locality where the plant had been seen; and I am happy to say that Mr. Taintor's researches were crowned with complete success, he having brought back fine living plants with the rhizomes attached, an examination of which, and comparison with authentic specimens of the drug from Mr. Hanbury and others, procured here, leave no doubt whatever of the species being the true officinal one.

The following account from Mr. Taintor's notes will explain how he obtained the plant:—"The locality is about one mile north of the small village of Tung-sai, situated upon the Bay of Pak-shá, at the southern extremity of the peninsula of Lui-chau-fú, or Lei-chau-fú, and directly opposite Hoi-haú, the port of Kiung-chau-fú in Haenan. The plant was growing at an elevation of about 100 feet above the level of the sea, in a very dry hard red soil, evidently composed of disintegrated volcanic rock. The plant grew in masses, which had been originally planted and cultivated, but were now apparently neglected and running to waste. The roots were in dense masses of sometimes more than one foot diameter, and with as many as twenty-five or thirty stalks springing from each. Rarely more than one or two of these stalks, however, bore flowers at the date of collection, January 5th. My plan, to ensure that I was getting the real plant, was to write the two characters *Liang-kiang* (*mild* or *gentle ginger*, the Chinese name), and tell an intelligent-looking villager that I wanted to see the flower. He led me, without the least hesitation, directly to the spot where I obtained the plants."

I must add that Mr. Swinhoe has since found the plant growing wild in dense jungles on the south coast of Haenan, one of his specimens being now before me, and that he has informed Mr. Hanbury, as I quite recently learnt from that gentleman, that there is good reason for believing that its fruit is the *Bitter-seeded Cardamom*, figured in Mr. Hanbury's valuable paper* "On some rare kinds of Cardamom."

In endeavouring to determine the specimens collected by Mr. Taintor, I found in my herbarium, for the purpose of comparison, only the Hongkong species of

---

* Galangal is not used in British medical practice; and even on the Continent, Endlicher speaks of it as "exoleti fere usus." The following statement of the export of this drug during the last three years is compiled from the official returns published by the Foreign Inspectorate of Maritime Customs, the quantities and value being, however, for greater convenience, reduced to British weight and currency.

Years.	From Canton.		From Shanghae.		Total.	
	Quantity.	Value.	Quantity.	Value.	Quantity.	Value.
	lbs.	£. s. d.	lbs.	£. s. d.	lbs.	£. s. d.
1867	32,800	123 10 10	79,200	354 9 9	112,000	478 0 7
1868	15,233	57 10 0	162,308	1149 3 5	177,641	1206 13 5
1869	None.	......	370,800	3046 16 9	370,800	3046 16 9

From this table it would appear that the demand for Galangal is increasing; but I cannot explain why the export of a product of the extreme south of China should be transferred from Canton (the nearest port) to Shanghae, situated 80 degrees further north.

* PHARM. JOURN. Vol. XIV. p. 418, fig. 8.

Alpinia, and a few Moluccan ones, received from M. Teijsmann, of the Buitenzorg Garden; whilst, as regards books, I was restricted to Roxburgh's 'Flora Indica,' the writings of Wight and Miquel, and the very useful 'Prodromus Monographiæ Scitaminearum' of Prof. Horaninow, published at St. Petersburg in 1862. With these somewhat slender *adminicula*, I was soon satisfied that the Galangal was either referable or else very closely allied to *A. calcarata*, Rosc. (which Roxburgh states to have been introduced from China into the Calcutta garden); and though I found some discrepancies between the Kwangtung specimens and the description of *A. calcarata* drawn up from the living plant by Roxburgh,* whose accuracy is so well known, yet these were apparently so few and unimportant that my chief ground of hesitation as to their identity was the extreme improbability that the rhizome of a plant widely cultivated within the tropics, and growing and flowering luxuriantly in the Calcutta, and also, according to Thwaites,† in the Peradenia garden, should have remained for so long a period unrecognized if really the same as the Lesser Galangal of commerce.

It being evident that this question, of so much interest in itself, could not be solved with the means at hand, whilst an approximate judgment would be valueless, I determined to let the matter lie over until I had access to more complete materials.

Since then I have received, through the kindness of Mr. Hanbury, a sketch, with a single flower coloured, of the plate of *A. calcarata*, given in Roscoe's 'Scitamineæ,' and a full-coloured copy of that in the second volume of the 'Botanical Register;' whilst my ever liberal friend Dr. Thwaites has sent me living rhizomes of the same species, whence have been reared fine healthy plants, though they have not as yet flowered, and, besides, copious specimens both of the flowering plant for the herbarium, and of the dried mature rhizomes. Mr. Taintor's Galangal plants have also again blossomed under culture, but set no fruit;‡ so that *fresh* flowering specimens of *A. calcarata*, and fruit of both species being alone wanting, I may claim to have had at my disposal as good materials for comparison as ordinarily fall to the lot of a descriptive botanist. I have, to the best of my ability, made a careful and exact comparative examination of living flowerless plants of each kind (including the rhizome), and of the mature rhizome of each; whilst I have compared the fresh and also the dried flowering plant of the Galangal with separate dried flowers, as well as herbarium specimens of the entire inflorescence of *A. calcarata*. The result is, that I am now entirely satisfied that the plant which furnishes the Lesser Galangal root is, though very closely allied to *Alpinia calcarata*, Roscoe, a perfectly distinct and well-defined species, the two differing in several particulars of structure, as well as in sensible qualities, as the following brief comparative notes will show:—

Alpinia calcarata.	*Galangal.*
Dried mature rhizomes chestnut-brown,§ conspicuously furrowed longitudinally; when cut across, with a stronger odour than Galangal, the cut surface remaining of a fuscous hue; of a bitter aromatic taste, much like cardamoms, with a distinct flavour of rhubarb superadded, but destitute of heat. Sheaths and bases of the young living stems or shoots more or less tinged with pink; tasting somewhat like rhubarb, but without any hot flavour. Leaves of a full deep green; aromatic, but not hot in taste. Ligulæ 3–6 lines long, rounded or truncate, and frequently bifid at apex. Racemes compound.* Flowers with an oblong concave bractlet at their base.† Labellum "yellowish, minutely punctated with dull red, and with veins of a deep dull red colour" (Thw.),‡ its veins thickish.	Dried mature rhizomes externally rufous-brown, only very finely striated longitudinally; when cut across, surface becoming rufous; aromatic and very warm in taste, as if made up of ginger and pepper, with a recognizable camphoraceous flavour, leaving a powerful sensation of heat in the mouth when chewed.§ Bases of young shoots white; tasting very warm. Leaves of a rather lighter green; hot in taste. Ligulæ 9–15 lines long, acutish. Racemes quite simple. Flowers without a bractlet. Labellum without the slightest trace of yellow, its veins very fine.

The fruits of both species, when known, may afford other marks of distinction.

A description of the Lesser Galangal plant, for which I propose the name of *Alpinia officinarum*, drawn up very carefully from living specimens, may fitly bring these notes to a close.

ALPINIA OFFICINARUM, n. sp.; rhizomatibus longe repentibus atque intertextis cylindraceis 6–9 lineas circiter diametro rufo-brunneis glaberrimis squamis magnis pallidioribus fibrosis demum secedentibus annulosque irregulares sinuosos albidos relinquentibus copiose instructis, caulibus 2½–3½-pedalibus, foliis bifariis longe vaginantibus coriaceis glaberrimis nitidis anguste lanceolatis basi angustatis sed non petiolatis exquisite attenuatis 9–14 poll. longis medio 10–12 lin. latis ligula magna (9–15 lin. longa) oblonga scariosa erecta basi decurrente vaginas marginante apice acutiuscula auctis, racemo terminali simplici erecto densifloro brevi (plerumque haud 4-pollicari) foliis superato, rachi tenuiter tomentella, bracteis‖ spathaceis involucrantibus binis exteriore viridi nunc folio abbreviato coronata interiore alba amba-

* 'Flora Indica,' ed. Carey, vol. i. p. 69.

† Enum. Pl. Zeyl. p. 320.

‡ Zingiberaceous plants when under cultivation, even in localities where they are native, are far less disposed to fruit than the same species in a wild state, the flowers usually dropping off as soon as they fade.

§ Described by Roxburgh as somewhat woolly and pale-coloured. Dr. Thwaites and myself find them perfectly smooth, both when young and at full growth. The young fresh rhizomes of both plants are quite white and succulent; but these can scarcely be alluded to: again, some dried rhizomes kindly supplied from the Calcutta garden are cinnamon-coloured; but these are of small diameter, and evidently immature. The full-grown ones from Ceylon are, as described, of a chestnut hue externally.

* So described by Roxburgh, and so I find them in all Dr. Thwaites's specimens; but represented as simple in Wight's plate (Ic. Pl. Ind. Or. vi. 2028), and also apparently by Roscoe, and in the 'Botanical Register.'

† Described by Roxburgh as "solitary, boat-shaped, white, 1-flowered," and shown in the Bot. Reg. plate, and also (so far as I can make out from the sketch) in that in Roscoe, but omitted in Wight's figure. Quite conspicuous in all Dr. Thwaites's specimens.

‡ Roxburgh describes the labellum as "deeply coloured with dark purple veins on a yellow ground." The Bot. Reg. plate represents it as crimson in the centre, with a broad yellow border, into which veins from the centre run, though not very conspicuously; whilst my copy of Roscoe's figure gives an oblong yellow centre dotted with crimson, and a broader margin striated with red and yellow, the latter colour slightly predominating. Considering the variation in colour of the flowers of *Canna*, and the differences of shade and marking in the labella of many cultivated epiphytes of the allied Order *Orchidaceæ*, it is perhaps unsafe to attach any considerable weight to a character of this kind.

§ Cæsalpinus characterizes the rhizome very accurately, though briefly, as "subrufa intus et extra, sapore Piperis, modice odorata" (De Plant. lib. iv. c. 62).

‖ Though these exist equally in *A. calcarata*, it is curious that Roxburgh makes no allusion to them; he would have called the two an *involucre*. There is likewise no indication of them in the figures of the 'Botanical Register,' Roscoe or Wight.

bus demum extus stramineo-arefactis nitidis intra margineque scariosis cucullatis flore pluries longioribus vel simul apicibus invicem convolutis basique solutis calyptratim secedentibus vel interiore paulo serius decidua, floribus ebracteolatis arcte subsessilibus 15 lin. longis, perigonio exteriore albo tubuloso tomentello apice breviter 2–3-lobo lobis scariosis rotundatis ciliatis, perigonii interioris albi tubo extus intusque tomentello lobis oblongis obtusis cucullatis 8–11 lin. longis 2–2½ lin. latis tertio paululum majore et latiore, labello albo medio striis vinoso-rubris juxta apicem in maculam distinctam flabellatim dilatatis percurso aliisque pallidioribus a lineis medianis interioribus marginem versus pinnatim radiantibus elegantissime picto sessili ovato integro apice acutiusculo vel bilobo crispulo-eroso 10 lin. longo 8–9 lin. lato basi corniculis binis rigidulo-carnosis subulatis subreflexis 1–1½-linealibus pilis capitatis consitis basique glanduloso-incrassatis conniventibus tubum occludentibus aucto, stamine labello dimidio breviore, ovario densissime albo-tomentoso, stylo apice sensim dilatato paulo ultra antheram producto, stigmate concavo margine ciliato, glandulis epigynis ⅔-linealibus luteolis oblongis apice truncatis integris vel lobulatis.

HISTORICAL NOTES OF THE RADIX GALANGÆ OF PHARMACY.

BY DANIEL HANBURY, F.R.S., F.L.S.

In discovering and describing the plant which yields the *Radix Galangæ minoris* of pharmacy, Dr. Hance has added an interesting chapter to the history of a substance which for many centuries has been an object of trade between Europe and the East. Galangal does not, indeed, possess properties which can claim for it the rank of an important medicine, being simply a pungent aromatic of the nature of ginger; but it has so long held a place in the pharmacopœias of Europe, and enters into so many ancient receipts, that I need hardly apologize for offering to the Linnean Society a few notes on its pharmacological history.

Galangal was apparently unknown to the ancient Greeks and Romans; at least no mention of it can be found in the classical authors. Its introduction into Europe was due to the Arabians, in whose writings it is noticed at a very early period.

Thus Ibn Khurdádbah, an Arab geographer who served under the Khalif Mutammid, A.D. 869–885, has left some information respecting China, after which he speaks of the country of Sila, which exports . . . . musk, aloes [*i. e.* aloes-wood], camphor, ... porcelain, satin, cinnamon [cassia], and *galangal*.*

The celebrated geographer Edrisi, who wrote A.D. 1154, observes of Aden, that it is the port for Scinde, India, and China, from which last country are brought musk, aloes-wood, pepper, cardamoms, cinnamon, *galangal*, mace, myrobalans, camphor, nutmegs, cloves and cubebs.†

The Arabian physicians, from Rhazes and Alkindi in the tenth and eleventh centuries downwards, make frequent reference to galangal as an ingredient of the complicated medicines then in use.

Among the later Greeks I cannot find any mention made of this drug prior to Myrepsus, who probably resided as physician at the court of the Greek Emperors at Nicæa in the thirteenth century; though several authors declare it is referred to much earlier. It is constantly named by Actuarius, who may have been contemporary with Myrepsus.

In a work published some years ago in Paris, entitled 'Assises de Jérusalem, ou Recueil des Ouvrages de Jurisprudence composés pendant le xiii^e siècle dans les Royaumes de Jérusalem et de Chypre,' * there is a remarkable list of commodities liable to duty during the twelfth century at the port of Acon in Syria (the modern Akka), at that period a great emporium of Mediterranean trade, in which many Indian spices and drugs, including *galangal*, are enumerated.

We find galangal also noticed, together with ginger and zedoary, as productions of India imported into Palestine, by Jaques de Vitri, Bishop of Acon in the early part of the thirteenth century;† and in the 'Romance of Godefroi de Bouillon,' a poem written in the twelfth century, it is named as one of the rarities of the East, which the Crusaders were deluded into believing would be found in plenty in the Holy Land.‡

Marco Polo, in his travels in Asia in the thirteenth century, observed galangal to be produced in Southern China (Province of Foochow ?), as well as in Java.§

About this period it was also known in Western Europe. St. Hildegard, Abbess of Bingen, who died in A.D. 1179, names it as *galgan*, and comments upon its medicinal virtues.||

Galangal is catalogued with other spices (as ginger, cinnamon, cloves, and nutmegs) in the tariff of duties levied in the port of Colibre (Collioure), in Roussillon, in A.D. 1252.**

A more interesting notice of the drug is contained in the journal of expenses of John, King of France, from July 1, 1359, to July 8, 1360, during his residence in England, preserved in the 'Comptes de l'Argenterie des Rois de France.' Besides purchases of sugar, mace, ginger, cloves, pepper, cardamoms, calamus aromaticus, and many other drugs, we find three entries for *galangal*, namely, for ½ lb. 18*d.*, for 2 lb. 6*s.*, and for 1 lb. 22*d.*†† As the price of gold happens to be also mentioned in one part of the account, it is easy to form an estimate of the relative value of galangal. This shows the price of 3*s.* per pound to be equivalent to 10*s.* of our present money—not extravagant for a commodity transported from the remotest Asia to the centre of England.

In Professor J. E. Thorold Rogers's 'History of Agriculture and Prices in England,' there are eleven entries indicating the price of galangal in England between A.D. 1264 and 1376. The highest was in 1307, when 2 lb. of the spice purchased for the Crown were paid for at the rate of 6*s.* 8*d.* The other entries indicate the price as from 1*s.* 6*d.* to 3*s.* per lb.

†† The original entries are as follows:—
"Lundy VII^e jour d'octobre. Jehan Kelleshulle, espicier à St. Boutoul, pour espices prises de li pour le Roy . . . . Galingal, demie livre 18*d.* Jeudy XIII^e jour de février . . . . Galingal, 2 livres, 6*s.* Samedy XXVII^e jour de juing . . . . Berthélemi Mine, espicier . . . . Galingal, une livre, 22*d.* . . . ."
L. Douet D'Arcq, 'Comptes de l'Argenterie des Rois de France au XIV^e siècle.' Paris, 1851, 8vo, pp. 218, 232, 265, 266.

In the fifteenth century galangal was evidently in common use; for Saladinus, physician to one of the Princes of Tarentum, *circa* A.D. 1442–1458, reckons it among the things *necessaria et usitata* which should be found in the shop of every *aromatarius*.* As might be expected, it is included in all the older pharmacopœias and antidotaria.

Garcia D'Orta, first physician to the Portuguese Viceroy of India at Goa, and a resident in India for thirty years, is, I think, the first writer to point out (1563) that there are two sorts of galangal—the one, as he says, of smaller size and more potent virtues brought from China, the other a thicker and less aromatic rhizome produced in Java.†

This distinction is perfectly correct. The Greater Galangal, which is termed *Radix galangæ majoris* is yielded by *Alpinia Galanga*, Willd., a plant of Java;‡ the lesser, called *Radix galangæ minoris* or simply *Radix galangæ*, is derived as we now know, from the plant which Dr. Hance has described as *A. officinarum*. It is the latter drug alone that is at present found in European commerce.§

The name *galangal*, *galanga* or *garingal*, *Galgant* in German, is derived from the Arabic *khalanjân;* whether that word may be a corruption of the Chinese name *liang-kiang*, signifying *mild ginger*, I must leave it to others to decide.

Let me say a few words regarding the uses of galangal. As a medicine, the manifold virtues formerly ascribed to it must be ignored; the drug is an aromatic stimulant, and might take the place of ginger, as indeed it does in some countries. That it is still in use in Europe is evident from the exports from China and from the considerable parcels offered in the public drug sales of London.‖ The chief consumption, however, is not in England, but in Russia.** It is there used for a variety of purposes, as for flavouring the liqueur called *nastoika*. The drug is also employed by brewers, and to impart a pungent flavour to vinegar, a use noticed by Pomet†† so long ago as 1694. As a popular medicine and spice, it is much sold in Livonia, Esthonia, and in Central Russia; and by the Tartars it is taken with tea. It is also in requisition in Russia as a cattle medicine; and all over Europe there is a small consumption of it in regular medicine.

There is doubtless some quantity of galangal of both sorts used in India. By a 'Report on the External Commerce of the Presidency of Bombay for the year 1865–66' I find that there was imported into the port of Bombay of "*Gallingall*" from China 520 cwt., from Penang, Singapore, the Straits of Malacca, and Siam 70 cwt., and from ports in Malabar 834 cwt. Of the total quantity (1424 cwt.), 716 cwt. was reshipped to the Arabian and Persian Gulfs.¶

According to Rondot, writing in 1848, the trade in this drug is on the decline;* and the statistics which I have examined tend strongly to show that this is the fact.

The foregoing notes may be thus summarized:—

1. Galangal was noticed by the Arab geographer Ibn Khurdádbah in the ninth century as a production of the region which exports musk, camphor, and aloeswood.
2. It was used by the Arabians and later Greek physicians, and was known in Northern Europe in the twelfth century.
3. It was imported during the thirteenth century with other Eastern spices by way of Aden, the Red Sea, and Egypt, to Akka in Syria, whence it was carried to other ports of the Mediterranean.
4. Two forms of the drug were noticed by Garcia d'Orta in 1563; these are still found in commerce, and are derived respectively from *Alpinia Galanga*, Willd., and *A. officinarum*, Hance.
5. Galangal is still used throughout Europe, but is consumed most largely in Russia. It is also used in India, and is shipped to ports in the Persian Gulf and Red Sea.

‡ *Maranta Galanga*, Linn. Sp. Pl. and Swartz, Obs. Bot.

§ Moodeen Sheriff, in his learned 'Supplement to the Pharmacopœia of India' (Madras, 1869), states that in the bazars of Hyderabad and in some other parts of India the rhizome of *Alpinia calcarata*, Rosc., is sold as a sort of galangal; and that a species of *Alpinia* growing in gardens about Madras, which, conceiving it to be new to science, he has described and named as *A. Khulinjan*, has a rhizome much resembling the Lesser Galangal of China.

‖ Three hundred bags, each 112 lb., imported from Whampoa were offered for sale by Messrs. Lewis and Peat, 27 Oct. 1870. The quantity was not thought remarkable; and I am assured that a single buyer will sometimes purchase such a lot at one time for shipment to the continent.

** Professor Regel, of St. Petersburg, and A. v. Bunge, of Dorpat, and Mr. Justus Eck, of London, have all obligingly supplied me with information as to the use of galangal in Russia. My thanks are also due to my friend Professor Flückiger, who on this, as on other occasions, has kindly offered me valuable suggestions.

SACCHARATED TAR, OR SOLUBLE VEGETABLE TAR.

BY M. A. ROUSSIN.

The value of vegetable tar as a therapeutic agent is generally recognized, but hitherto, in consequence of the small extent to which it is soluble in water, its use has been limited. Many attempts have been made to secure a greater solubility, but this has only been obtained by the employment of alkalis,—that is to say, by saponification. But saponification undoubtedly modifies the elements of the tar, and partly destroys its curative properties.

According to M. Adrian, "these preparations do not correspond by their chemical composition to the therapeutic properties that are expected in them," and he states that he has found alkalis, as well as acids, to modify the resinous qualities that are the basis of the medicament.

Dr. Jeannel has expressed a similar opinion. He says it is necessary that the tar should be emulsed by a neutral substance, since by so doing all the natural properties of the tar would be preserved.

Impressed with the correctness of this idea, M. Roussin sought to adapt to vegetable tar the same process by which he was able, on a former occasion to form an emulsion with balm of copaiba.† At that time he proposed to use sugar for facilitating the emulsion of copaiba in water, and as a corrective of the repulsive taste of that substance. Sugar being a neutral substance, without any chemical action capable of modifying the composition or curative properties of medicinal substances; and daily associated without hesitation with all kinds of remedies.

After several attempts this problem was resolved, and a complete solution of the vegetable tar in water obtained. The emulsion of tar was effected by triturating in a porcelain mortar, so as to obtain a homogeneous paste, purified tar, powdered sugar and powder of gum arabic. A small quantity of water was added to obtain an emulsion: it was then left to stand, and afterwards

* 'Commerce d'Exportation de la Chine;' Paris, 1848 p. 98.

† 'Annales du Comité Médical des Bouches-du-Rhône,' t. v. p. 67.

decanted. This saccharated emulsion had not the repulsive odour of the emulsion prepared with an alkali; it possessed the odour of tar, and a taste neither sharp nor bitter. It was miscible with water in all proportions, so that, by estimating the quantity of tar present, a solution might be prepared instantaneously, containing any required quantity of the active principle.

But the liquid form of the medicament presenting many and serious inconveniences, it appeared to M. Roussin that the pulverulent form, with all its practical advantages, would be very desirable. He therefore pursued his researches until he succeeded in obtaining a saccharate, as a yellow powder only differing from sugar in appearance by its colour, and exhaling the balsamic odour of tar. This preparation constitutes a remedy essentially new in form, and appears to be the real and complete solution of the problem of Dr. Jeannel.

The saccharate of tar is constant in its composition. It contains 4 per cent. of purified vegetable tar. A teaspoonful (5 grammes) thus represents 20 centigrammes of tar, and will suffice for the preparation of a litre of water.

According to M. Bouchardat, 30 grammes of tar-water contain nearly 1 centigramme of the principles of the tar in solution. This would be nearly 30 centigrammes to the litre. Soubeiran says that the proportion of matter dissolved in tar-water is so small that 100 grammes do not contain 4 centigrammes (less than 40 centigrammes the litre), and that patients can scarcely support the tar-water unless it be diluted.

The irritation of the stomach often provoked by the tar-water of the Codex is prevented by the saccharate; the proportion being but 4 per cent., the acridity of the tar is covered. Another advantage, not less important, due to its pulverulent form, is that it avoids the necessity of swallowing a large quantity of liquid, since a glass of water is sufficient to dissolve several teaspoonfuls. The physician can thus augment the quantity of tar according to the necessities of the patient.

The pulverulent form has another valuable advantage. Patients who are unable to overcome the repugnance the odour and taste of tar often provoke, may enjoy the benefits of this therapeutic agent, by making up the saccharate into a pill with unleavened bread.

Gay, speaking of the acridity and repulsive taste of oil of tar, recommended that it should be sweetened, "in order to mask its flavour and its odour." Sugar, as I have said, does not alter the therapeutic properties, but modifies its organic properties and facilitates its absorption. While retaining the odour and taste of the remedy, the saccharate so disguises them that the most delicate stomachs can bear it without repugnance.

The saccharate of tar is not the result of a chemical reaction; it is a simple mixture, each of the elements of which retains intact its composition and its properties. Constant in its composition, it will furnish solutions really and mathematically entitled to the name, being able to fulfil all the conditions necessary for mixtures, gargles, injections, etc., and enabling the physician to give his patient such quantity of tar as he may deem necessary.—*Journal de Pharmacie et de Chimie.*

The Great Glass Bottle.—It was an odd, dingy, old-fashioned shop, with huge gables and overhanging eaves—interesting, no doubt, in an antiquarian point of view, but giving the ordinary passer-by the somewhat uncomfortable sensation that in going underneath its projecting windows there was a very considerable risk of the building falling bodily upon his head. Verily, the old house had seen its best days; but still (old, dingy, and dilapidated as it was), it very well suited its occupier—Jonas Tregaskis, druggist. In those days, before "pharmaceutical chemists" were invented, men who dealt in drugs were content to call themselves druggists, adding sometimes thereto the not very euphonious or attractive title of drysalter; albeit it is possible quite as many people are poisoned by drugs now-a-days as there were then. Well, then, within the shop of Jonas Tregaskis there was the usual supply of mysterious-looking jars and gallipots labelled with odd words known only to the initiated, and sometimes it would seem not very well known even to them, such as "Galbanum," "Hydrag. s. creta," "Cap Papr.," not to mention the extraordinary-looking circles and triangles which were engraven on those that stood on the top shelf, and of which not even old Jonas himself knew the meaning. But it was not these which constituted the glory of the establishment, it was not upon these that Jonas daily cast an eye of pride and his apprentice an eye of envy. No! it was the huge red glass bottle which stood in the window and gazed like a great red eye of fire, when the lamp in the window had been lighted, upon every one that passed. Now this bottle was a new acquisition of the druggist's. He had bought it, in fact, only the month before from the widow of a respected member of his trade in an adjoining town. Well, then, the bottle had for that space stood quietly and calm in the shop window. It had not yet recovered the shock occasioned by so sudden a removal from the premises it had hitherto occupied to the somewhat dingy abode of Tregaskis; but the feelings so long pent up at last found vent, this being (so the bottle mused) somewhat as follows:—"Here's a treat, to be shut up in this nasty, dingy, little hole, with no society except those vulgar jars and gallipots! No! insufferable! insufferable!" As the bottle pronounced these words it quivered from top to bottom. "Ah!" cried the druggist, suddenly looking up, "it is as I feared; that bottle is rather top-heavy." "Well," continued the bottle, "what a view for any respectable bottle to look at! Faugh! it's enough to turn one sick; these overhanging windows, and that chandler's shop opposite, with the strings of dips in the windows. What a horribly low neighbourhood; my old master's premises were bad enough, but as to these"—here the bottle again trembled with such vehemence as to attract the druggist's attention. "Tell you what it is, Ben," said Jonas to his boy, "it's my opinion that bottle isn't safe." "Heigh ho! what a life to lead," continued the bottle, "nothing to do but to stand here all day to be looked at; even excess of admiration becomes tiresome! Therefore I am resolved to put in execution a plan which I have long contemplated; it is very evident a sedentary life does not suit me. I am convinced that I was born to be a roamer, so here goes for a start. The world and liberty for ever!" As the bottle uttered these words, whether it was that it leapt off the shelf, or whether the sudden passage of a brewer's dray at that particular moment had anything to do with it, it is impossible to say; however, the fact was that it precipitately fell headlong from the shelf, nearly frightening the druggist out of his wits, and quite frightening his apprentice out of his—at least, all he had to be frightened out of—and was broken into a hundred pieces. "Ah!" said the druggist, as he and the boy picked up the bits and wiped up the red fluid which had run out all over the floor, "it is as I feared, that bottle had not *enough bottom.*" As with bottles, so, oftentimes, with people; they talk and talk of what they mean to do, but when they pass from talk to action they invariably end in failure, they metaphysically fall to pieces, they have not *enough bottom.* Thus it is, too, one often sees shops get shut up, and the plate glass windows, once all brightly decked, get whitened over, and placarded with bills announcing "Peremptory Sale!" Afterwards the shutters go up, and whisks of straw flit vaguely round the door, and women and children weep, while wise men shake their heads and sigh; and all for the want of *bottom.*—(A Big Brother.) *The Bristol Times and Mirror.*

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 23, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

ILLEGAL SALE OF POISONS.

The two cases reported this week in which fines have been inflicted for infringement of the provisions of the Pharmacy Act, 1868, show very well that abundant protection is afforded to the public against those who illegally sell dangerous drugs or deal in them without due care, and that it is in the power of any one to obtain the punishment of those who offend in either way.

As regards the Islington case we cannot, (taking the report as a truthful statement of it,) perceive any extenuating circumstance; and the plea urged by the defendant's solicitor that labels were not uncommonly mixed together, far from disproving neglect seems to establish it; for what is the use of a label but to indicate correctly the nature of the thing labelled? and what can be the use of a label put on without its being read at the time?

The Essex case is still more remarkable; and we cannot avoid the belief that the reporter must have strangely misinterpreted some of the magistrates' remarks. It will be seen on reference to the report that the most extraordinary confusion appears to have prevailed as to the qualifications requisite for the sale of drugs. A "licence to sell" after the manner of publicans seems to have been the dominant idea of the magistrates, and the Excise authorities were taken to be the qualifying body. But the need for a thorough knowledge of drugs and their preparation seems to have been only vaguely entertained.

We hope that the provisions of the Pharmacy Act will receive more careful consideration from magistrates, for, as we lately had occasion to remark, it is highly desirable that the law should be applied rightly as well as vigorously.

PHARMACEUTICAL PRIZES.

We notice among the announcements of vacancies connected with pharmacy one issued by the Poor Law Guardians of Manchester which seems deserving of attention now that the competence of dispensers is not only considered desirable, but even demanded as a necessity. Without commenting upon the strange confusion of duties involved in making a dispenser of medicines also the head-nurse of an infirmary, we think it worth while to quote from two other advertisements appearing side by side with that above referred to, the particulars of salaries, etc. offered by the Poor Law Guardians of Manchester and Salford as remuneration for the respective services of a cook, a horsekeeper, and a dispenser of medicines:—

Cook . . .	£20	per annum	with board, washing, and lodging.
Horsekeeper	£26	per annum	with board and lodging.
Dispenser, etc.	£30	,,	with board, lodging, and washing.

It is worthy of note that the qualification required of the dispenser is not mentioned in the Manchester advertisement, so that there is a doubt what the Guardians expect or think needful in that way. In another announcement of a similar vacancy in the Greenwich Union, however, the applicants are required to be either Licentiates of the Apothecaries' Company (*sic*) or registered under the Pharmacy Act, 1868, and in this case the remuneration offered is £80 per annum, with unfurnished rooms, coals, and gas, but no rations. Surely the responsibility attached to the duties of a dispenser has not been duly considered by the guardians in either case.

NOTES ON HERBARIA AT HOME AND ABROAD.

Some interesting details concerning home and foreign herbaria were given in Mr. Bentham's recent anniversary address to the Linnean Society, from which we gather the following. It was premised that although zoological museums are by far the more expensive, yet as exhibitions they can draw largely on the general public, whilst herbaria have to rely on science alone, which is always poor. Both, however, may claim national assistance on the plea of instruction as well as of pure science; and for practical or economic purposes the herbarium is even more necessary than the museum.

To mention our own herbaria first. The great national herbarium and library at Kew is now far ahead of all others in extent, value and practical utility. Originally created, maintained and extended by the two Hookers, father and son, their unremitting and disinterested exertions have obtained for it that Government support without which no such establishment can be really efficient; whilst their liberal and judicious management has secured for it the countenance and approbation of the numerous scientific foreigners who have visited or corresponded with it. Of the valuable botanical materials accumulated during the last century in the British Museum nothing definite can be said, the natural history portion of that collection being in a state of transition. There are also herbaria of considerable extent at the Universities of Oxford, Cambridge and Edinburgh, and at Trinity College, Dublin; and a hope is expressed that the necessity of maintaining and extending them will be recognized by those great educational bodies.

The herbarium at Melbourne, Australia, founded by FERDINAND MUELLER, has, through his indefatigable exertions, attained very large proportions; while that of the Botanical Garden of Calcutta, under the successive administrations of Dr. THOMSON and the late Dr. T. ANDERSON, has recovered in a great measure its proper position. In the United States the herbarium of ASA GRAY, recently secured to the Harvard University, now occupies a first rank.

On the Continent, of the many important private herbaria formerly existing in Paris, two only, those of JUSSIEU and A. DE SAINT-HILAIRE, had, previously to the late disastrous events, been secured for the national collection. WEBB's had gone to Florence; J. GAY's, which would have been of special value at the Jardin, was purchased by HOOKER, and presented by him to Kew. The celebrated herbarium of DELESSERT is removed to Geneva, whilst his botanical library, one of the richest in existence, is locked up within the walls of the Institut. These are but partially replaced by M. COSSON's herbarium, which has much increased of late years, and to which he added last spring the late SCHULTZ-BIPONTINUS's collection, rich in *Compositæ*. The national herbarium of the Jardin des Plantes is still one of the richest, but no longer the richest of all. The limited funds at the disposal of the administration have allowed of their making but few acquisitions, and the staff is so small and so limited in the hours of attendance that the increase of the last twenty years remains for the most part unarranged; the library, too, is very scanty.

At Geneva the Delesserian herbarium has been adequately accommodated in a building near to the natural history museum now being erected. While in Paris, it had been for some time comparatively useless, owing to an attempt to class it according to SPRENGEL's 'Linnæus;' but now an active amateur committee—Messrs. J. MUELLER, REUTER, RAPIN, and others—have already made great progress in distributing the specimens under their Natural Orders; and Geneva, already containing the important typical collection of DE CANDOLLE, and BOISSIER's stores, rich especially in Mediterranean and Oriental plants, has become one of the great centres where real botanical work can be satisfactorily carried on. At Munich, the Bavarian Government having failed to come to terms with the family of the late VON MARTIUS, his botanical library has been dispersed, and his herbarium removed to Brussels, where it is to form the nucleus of a national Belgian collection. At Vienna, the Imperial collection is admirably housed in the Botanical Garden in good order, with the advantage of a rich botanical library in the same rooms. At Berlin, where the Royal Herbarium has always been kept in excellent order, want of space is greatly complained of since it has been transported to the buildings of the University. At Florence, the difficulties with regard to the funds left by Mr. WEBB for the maintenance of his herbarium have been overcome, and it is hoped that the intentions of the testator, who made this splendid bequest for the benefit of science, will no longer remain so shamefully unfulfilled. To the above may be added Leyden, Petersburg, Stockholm, Upsala and Copenhagen, as towns possessing herbaria sufficiently important for the pursuit of systematic botany; but at the time of Mr. BENTHAM's visit, some years ago, they were all in arrears of arrangement, though in this respect they may have improved since.

THOUGH poisonous properties prevail to a great extent throughout the *Euphorbiaceæ*, many of the plants are highly valuable both for food and medicine; the seeds of many of them abound in oil more or less acrid and purging, as *Ricinus communis* and *Curcas purgans* for instance; some have the disagreeable habit of their relatives, the nettles, and are armed with powerful stings. An interesting genus on this account is *Cnidoscolus*, two species of which are formidable enemies to come in contact with. *C. quinquelobus*, better known perhaps as *Jatropha urens*, is one of these. It is a native of South America and has been in cultivation in hot-houses in this country, but the effects of its sting are so dreadful that collectors and gardeners have a wholesome dislike to it. The first sensation of a sting from this plant is a numbness, often accompanied by swelling of the lips, it frequently impedes the circulation, and in some persons produces unconsciousness for a length of time. The pain is very severe and lasts for some days; it is said that the part touched by the sting remains swollen for a length of time accompanied by a constant itching. Another species (*C. stimulans*), a native of the Southern States of North America, has palmately lobed leaves from four to six or eight inches long, covered with long, stinging hairs. The plant has received the name of "Tread-softly," on account of the stinging hairs causing much pain to the bare feet of negroes who walk inadvertently amongst the plants. The roots are said to be nutritious and used for food.

AT a recent meeting of the Massachusetts College of Pharmacy, the following gentlemen were elected honorary members:—Professor T. REDWOOD, Ph.D., Professor J. ATTFIELD, Ph.D., DANIEL HANBURY and HENRY DEANE, of London; H. B. BRADY, Newcastle-on-Tyne; Dr. H. HAGER, Berlin; Professor F. MOHR, Bonn; Dr. G. C. WITTSTEIN, Munich; Professor F. A. FLÜCKIGER, Bern; Professor DRAGENDORFF, Dorpat.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Boiled Oils and Varnishes.

BY CHARLES W. VINCENT, ESQ.

My chief desire on the present occasion is to render as complete an account of the process of oil-boiling by steam as I can, without committing any breach of confidence towards those for whom I have been professionally engaged. A certain amount of reticence is necessitated by this latter consideration, but, at the outset, I may state that it applies only to the particular substances used to give the necessary drying or solidifying qualities to boiled linseed oil, and hence technically termed driers. The process itself may be used with any of the substances commonly employed in boiling oil by fire for the same purpose. The apparatus employed and *modus operandi* being well known throughout the trade, I am rather benefiting than injuring the cause of the manufacturers by publishing an account of the present state of a mode of manufacture which must eventually become the principal source of boiled oil.

The first consideration which presents itself to a practical man on approaching a subject which he wishes thoroughly to master and understand is, What do I want to do? the second being, How can I do it? Viewed in this way, it became evident to those engaged in this research that oil-boiling might be reduced to a much more simple and perfect operation than that ordinarily pursued.

The principal worker who has published the result of his researches is M. E. Chevreul, who, in 1856, in an admirable paper in the *Annales de Chimie*, definitely pointed out that the act of drying of linseed oil is one of absorption of oxygen, and consequently might more properly be termed solidification than drying (we will, however, retain the accustomed term); next, that many driers act catalytically; and lastly, that too long boiling retarded the drying of the oil. For instance, oil boiled three hours without driers, and afterwards three hours with litharge, dried more slowly than the same oil boiled for three hours with litharge, without any previous heating.

To whom the next discovery is due, viz. that the high temperature attained in oil-boiling by fire, is unnecessary I do not know. I discovered the fact for myself in 1859–60, when engaged in a research for Messrs. Leighton Brothers, of the *Illustrated London News*, on varnishes for printing inks; and at that time I introduced a mode of steam oil-boiling and varnish making which is still carried out by some of the largest makers of printing inks and those kinds of varnishes. The fact is now very generally accepted, though some manufacturers still hold aloof.

There are reasons which interfere with, and which stop the progress of many arts and inventions, though against reason, and the oil trade is not free from these drawbacks. A principal one is, that the manufacturers are in a great measure tied down by the wishes and desires of their customers, so that in many cases they have to produce rather what the consumers think they require than what they really need. It is this multiplicity of objects which causes the great variety of modes of manufacture of linseed oil for painting purposes. It is a common case to find that what one person, a large consumer, calls a thoroughly good boiled-oil, his neighbour, an equally large consumer, will pronounce entirely unfit for use. Now, it is my earnest wish that, as far as possible, you should hold yourselves free from preconceived notions of what constitutes a good boiled-oil or varnish conventionally, and, considering merely the uses to which they are required to be put, reflect how far these requirements are met. My own personal experience has placed certain points before me as of paramount importance, and to these I shall direct your attention. Those characteristics which may be essential to the good quality of one mode of boiling oil, but do not forward results produced when these articles are applied to their various uses, I shall neglect.

Before entering upon my subject, I must remark that no paper read before the Society of Arts on oil-boiling and varnish-making can be complete and appropriate without at least some allusion to that communication on the subject presented by Mr. J. Wilson Neil, for which the Isis Gold Medal was awarded to him in the session 1832–3 of the Society, which was published in the 'Transactions,' vol. xlix. part 2. It is not within the scope of the present paper to treat of the modes of manipulation, recipes, and precautions which he there so fully, carefully, and, indeed, conscientiously describes; but the fact remains that that paper was the foundation, and remains so to this day, of all the published accounts of modes of manufacturing varnishes. The alterations and modifications which have been from time to time worked out, are more in the shape of mechanical appliances for facilitating rapidity, easing labour and providing greater safeguards against fire, than improvements of process. The principle of manufacture remains the same, and the varnishes now made cannot be said to be better in quality, though they may be made at a less cost, and in shorter time, than those produced under the processes detailed by Mr. Neil. Many firms still retain modes of operation almost (in some cases quite) identical with those he describes. The paper is still of such value that the Society would, even now, confer a benefit on the trade were they to republish it.

For a process of oil-boiling by fire, Mr. Neil's is nearly perfect; the new process depends on principles entirely different from those he dealt with, and therefore it is necessary to begin the subject, as it were, *de novo*. Linseed-oil is boiled for two reasons, as you all know; firstly, in order to facilitate its drying when spread on thin surfaces, either alone or mixed with paint; secondly, that it may serve as a vehicle for the mechanical suspension of the finely-divided particles constituting a paint; that it may give a certain cohesive power to the mixed paint so constituted, enabling it to adhere to the surfaces on which it is spread, neither running into drops, nor leaving the colouring matters behind, but carrying the whole of the colour evenly diffused through it over the whole surface upon which the paint is laid, and, when dry, forming together a surface which is, as far as may be, impermeable to gases and liquids. Technically, these are the two qualities which consumers rightly agree in desiring in boiled oil,—that it should be a quick-drying oil, and have a good body. But it is frequently the case—and, in my opinion, they err in so doing—that consumers require in boiled oil, besides these two essential qualities, others in reality quite adventitious, to which, either from experience of some particular sample, from the custom of their trade, or from the mode in which they have been led to believe good boiled oil alone can be made, they attach a fictitious importance. It is of every-day occurrence that, unless the oil complies with these artificial demands, it is unhesitatingly condemned, independently of the two essentials upon which all are agreed. For instance, some persons attach the idea of a particular smell to be a good sample of boiled oil. If all were agreed as to what that smell should be, the desire would be easier to satisfy; but, taking it for granted that the smell is a guarantee that the oil has been heated for a certain time at a certain temperature, it is obvious that two samples of oil may have that odour, whilst from the different ages of the oils previous to boiling, the quality of the seed from which they were expressed, or the driers employed, their qualities of drying and body may be widely different. Other persons, again, confine in their opinion good quality to a particular shade of colour and degree of brightness. A third party requires a particular shade of colour, body and smell combined. Others quarrel with the manufacturer if he vary his standard shade of colour, smell, etc. The truth is, that these are circumstances independent of the proper treatment of the oil. The varying qualities of oil require a varied treatment to bring them to one standard of body and drying power. If these be the standards to be maintained, the others, which after all are only indications that the oil has been manufactured, are of no importance. This applies to the ordinary process of boiling oil by fire, and I do not insist but that, if a uniform quantity of oil be employed, and the same process always pursued, the colour and smell would be indications of the success of that particular process upon that particular oil; but, at the present day, the field from which you obtain linseed-oil is much wider than it was of old: you cannot always buy the oil you prefer, and, of necessity, the mode of manufacture you adopt has to some extent to vary. If once the idea be thrown over that a high temperature is essential to the preparation of a good boiled-oil, you at once obtain modifications of these peculiarities of colour and odour, though the other qualities, body and drying power, may be the same, or even increased.

With these preconceived notions it is that the new process of oil-boiling had and still has to contend, people imagining that unless the boiled-oil attains a conventional standard of appearance, it of necessity must be bad. One of the advantages of the new process is hereby much diminished, since oil-boilers have to adopt expedients to give a colour to the oil which otherwise it would not have to nearly the same extent. And to the practical man an aim has to be added which frets and annoys common sense and honesty of purpose, viz. that in addition to that of good and improved methods of manufacture, there must be sufficient similarity in appearance to accustomed samples to avoid awakening those prejudices against anything new, merely because it is new, still largely existing amongst the mechanical part of our population. It is the more to be deplored, since the colour of white zinc, delicate blues, etc., are much deteriorated by the dark oil used for mixing with them.

I discovered, in the beginning of 1860 that, with suitable driers, I could obtain an oil which, although it had never been raised above the temperature of 228° F., nevertheless had the body and the drying power of a good boiled-oil. This led me to investigate the subject further; although the trade being limited, and the persons engaged in it having acquired a certain reputation for a good merchantable article, made by processes which they have not unfrequently worked out for themselves, they have not the same incentive to seek for improvements, or even to adopt them when brought before them, as exists in many other manufacturing processes. I do not claim any merit as an originator of steam oil-boiling, for I have reason to believe that it has been practised in Germany for many years past; but, as far as I am personally concerned, I may state that all I know concerning the process I have discovered for myself, not even being aware that it was practised by others for some years subsequently to my own discovery and use of it.

Chevreul's experiments, to which I have previously alluded, form a good substratum for a disquisition on this subject. The principle being clearly laid down that it is the absorption of oxygen by linseed-oil which causes its solidification, it follows that all the substances which can be used as driers must be such as are capable of parting with oxygen or dissolving in it, and, being themselves oxidizable in combination, they in that way increase its absorptive power. There is a class of driers which act whilst mechanically suspended in the oil, as white copperas, etc., for example, increasing its absorptive power by their presence, but leaving no increase of drying power when withdrawn.

The substances which act catalytically belong, in my opinion, to the first class. They part with some of their oxygen to this oil, become to a certain extent deoxidized, and again coming in contact with air, they reassume their primal condition, and are ready to do the same work over again. It is this necessity of reoxidation which caused the introduction of blowing-machines for oil-boiling, when their own proper advantages in rapidly giving body to linseed-oil at comparatively low temperatures were at once, and to me unexpectedly, made manifest. These catalytic driers are now generally adopted, the effect of their use being simply this (and you will see that the result is a great advance upon previous methods), that by treating the oil with these driers under the influence of heat and air, its own absorptive powers for oxygen are greatly increased, and remain so when the primary incentives to absorption are removed. This likewise has to be borne in mind, that what we want to do is not to render the oil solid or partially so now, but to enable it to become so when exposed to the air.

Many years ago, the late Professor Faraday was consulted as to the possibility of hastening the drying of printing inks, so that work might be milled (that is, compressed between zinc plates passed through closely-set rollers) with less delay after printing. A fortnight was the usual time taken, and, if ordinary driers were used, the whole of the ink would skin on the rollers, with many other inconveniences. Faraday's far-sighted sagacity at once decided that one solution of the difficulty would be by the mechanical introduction of a substance to act as a drier which should be inert till it was exposed to the air. As Professor Faraday's advice and assistance, in a research on the same subject for the same firm was of material service to me, and, indeed, enabled me to supersede the drier in question, I break no confidence by stating that it was binoxide of manganese which almost without experiment he at once pitched upon. By what process of thought he chose this substance I do not know, but the fact remains that he did so introduce it, and for, I think, between thirty and forty years it was used by the same firm. At the Queen's Bible office they mill their work three days after printing, if it prove necessary. In order to get the binoxide in a state of division sufficiently fine to mix with printing-ink, he devised a series of washing receptacles, like successive stairs, the finer particles passing on to the lower vessels, being longer suspended than the coarser—a simple yet ingenious arrangement, which enabled the ink to be worked without any risk to the plates or formes from grit.

By properly pursuing this investigation, many other substances have been discovered which exercise this property in a high degree. Without becoming in any way altered, they induce an alteration in the linseed-oil subjected to their operation. We may imagine the action as similar to that by which spongy platinum explodes a mixture of oxygen and hydrogen, or a platinum wire is kept red-hot by the vapour of ether.

Litharge and the other salts of lead perform the same office whilst in solution in the oil, and to their presence, for the most part, is the dark colour of boiled oil due. Where the steam process is used, the oil never reaches a sufficiently high temperature to produce carbonization. By judiciously mixing one of the substances acting catalytically and a lead salt, a drier is obtained, by altering the relative proportions of which the boiler is enabled to produce any required shade of colour. The larger the quantity of litharge, the darker the colour of the boiled oil. A lesser proportion of litharge, accompanied by a greater quantity of the catalytic drier, gives as the product an oil which will dry in the same time, and has less colour. These are the principles of oil-boiling by steam.

The risk of boiling over, and being the cause of a conflagration, was one reason for the distance at which oil-boiling businesses were formerly kept from towns; the abominable smell produced by the evaporation and partial decomposition of the oil was another. Nevertheless, it is not convenient, in the extension of businesses of a disagreeable character, to be constantly driven from the centres of industry, where their articles of manufacture have ultimately to be used, and this has been particularly the case with the oil trade. In a place like London, a very large part of the consumption of boiled oil must be local; or if the oil be exported, it is the same thing as far as the manufacturer is concerned, each mile he is driven away from his customer decreasing his profits without any corresponding advantage. It became, therefore, a matter of absolute necessity that means should be taken to stop the intensely disagreeable smells arising from oil-boiling, tainting, and poisoning the air of the surrounding neighbourhood. This has been arrived at in a perfect manner, as an adjunct of the steam process.

The best form of pan for oil-boiling is made of copper, on account of its conducting heat better—an iron one will give equally good results, a little more time being, however, required—circular in shape, with a depth about equal to its diameter, and a rounded bottom. This pan is surrounded for half its depth with an iron jacket, between which and its body steam is admitted as the source of heat.

(*To be continued.*)

Parliamentary and Law Proceedings.

The Serious Charge against a Chemist at Rotherham.

At the Rotherham police court on Thursday, before G. W. Chambers, Esq., and H. Jubb, Esq., Mr. William Collinson, chemist and druggist, Masbro' Bridge, Rotherham, was brought up in custody charged, "that he did use a certain instrument with intent to procure miscarriage to a certain woman, named Eliza Uttley," twenty-seven years of age, daughter of Samson Uttley, living near Greasborough. Rumours concerning the circumstances of the case had got noised abroad, and as the prisoner has occupied a very respectable position in the town, and was well known, the court was crowded. Mr. Edwards was the solicitor for the prosecution, and Mr. Whitfield defended the prisoner.

Mr. Edwards expressed very great regret that he had to appear to prosecute the prisoner, who had for a long period occupied a respectable position in the town. No one would be more glad than himself if the prisoner should be able to clear the stain from his character which the charge implied, but he was afraid, from the conclusiveness of the testimony it would be his duty to lay before the bench, the prisoner would be unable to do so. What he then proposed to do was to place before them evidence as to the death of the girl, Eliza Uttley, who, he had been informed, had died that morning about four o'clock, and to show that her death had been caused by the use of an instrument by the prisoner to procure abortion. From a declaration which had been made by the girl before her death, they would see that the facts lay in very small compass. It would seem that the girl was in the family-way, as she alleged, by the prisoner, and that knowing her condition, she went to him and told him. He advised her to get rid of the child, and she consented that instruments should be used to procure abortion. She was prematurely delivered of a dead child, and the poor girl herself had also died. If he proved to them some of those statements, it would be quite sufficient to warrant them in remanding the prisoner. The inquest, he was told, would be held on the following day.

Samson Uttley, of Greasborough, the father of the deceased, was then called. He stated that he had a daughter named Eliza. She died at half-past four o'clock that morning.

James Edward Long, doctor of medicine, Park Gate, was then examined. He said: I was called in to attend the deceased on Sunday night last about nine o'clock. I had not previously known her. She was then in bed at Westfield House, which lies between Rawmarsh and Greasborough. I examined her and found she was suffering from peritonitis, that is to say, from inflammation of the membrane lining the cavity of the abdomen. I cannot explain what the cause of this inflammation was. It would be impossible to give any explanation now other than mere supposition. I found nothing in the womb. I examined her rather casually, because she was suffering very great pain, and I considered it would not be wise to make a minute examination, as it would materially add to her sufferings. I, however, intended to examine her the next day, and accordingly I went and saw her early on the following morning, and examined her more closely. From the appearance of the womb I suspected she had had a miscarriage and that peritonitis was resulting from it. I have seen this morning a fœtus which has been found by Mr. Horne, and my opinion, after a minute examination is, that it is of quite five months' growth. Whose child it is I do not know.

Cross-examined by Mr. Whitfield: Peritonitis may arise from a variety of causes, and might ensue after an ordinary confinement under certain circumstances. So far as I can judge, she died from peritonitis. I have examined the fœtus. It is not in my charge, but is in the hands of the police. When I examined it I did not observe anything special about it. It was then scarcely in a state to be minutely examined, but it will be examined hereafter.

Mr. Edwards: I propose now just to put in the declaration by the deceased, taken before Mr. Jubb while she was in the immediate prospect of death.

Mr. Whitfield: I have no objection to its being put in, if you put it in properly—in the ordinary way.

Henry Jubb, Esq., Justice of the Peace for the West Riding of Yorkshire, was then sworn. The declaration alluded to by Mr. Edwards was placed in his hand, and he then said: This is the declaration of Eliza Uttley, which I took on the 12th instant, in the capacity of magistrate.

Mr. Edwards: Did she make the declaration while in the expectation of immediate death?

Mr. Whitfield: How can Mr. Jubb say?

Witness: The document will speak for itself.

Dr. Long, recalled, examined by Mr. Edwards: At the time the declaration was taken the woman herself expected death.

Mr. Whitfield: I see that is stated in the declaration here. You need not go on.

Mr. Edwards: I thought you wanted the making of the declaration proved.

Mr. Whitfield: I wanted it putting in properly.

Mr. Jubb, cross-examined by Mr. Whitfield: The declaration was not made upon oath. Mr. Oxley, Dr. Long and myself were present when the declaration was taken. This declaration was made by the girl in answer to questions put by Mr. Oxley.

Mr. Whitfield here requested that this statement might be taken down in writing. The depositions were not being taken now, but he considered it to be of some importance that the statement should be put in writing. This procedure was not usual in ordinary cases, but in extraordinary cases like the present one he thought it ought to be done, seeing that the statement was considered to be of an important character.

The Chairman ruled that as the depositions were not being taken, Mr. Whitfield was out of order in asking that the statement should be taken down.

Mr. Whitfield: I have no doubt the statement is of the utmost importance, and, that being the case, I think it should be on record.

Mr. Edwards submitted that it was quite unnecessary that any statement should be taken in writing then. Suppose he put it to them this way: That in consequence of the absence of material witnesses he was unable to go on with the case. They would then have it in their power to remand the prisoner.

Mr. Whitfield: Well, I do not see any objection to your application.

Mr. Jubb, cross-examined by Mr. Whitfield, continued: Mr. Oxley asked the girl the questions, and I wrote down the answers.

Mr. Whitfield: I, of course, can have no possible objection to the present application for a remand in this case, but it must be understood that there are very grave objections to the admissibility of this document, and it will be my duty when the proper time comes to submit that this document is not admissible in evidence. However, it is not necessary for me to do so now. Only let the remand be for as short a period as possible.

Mr. Edwards: Monday will do.

Mr. Whitfield: Will you be disposed to admit the prisoner to bail?

The Chairman: No, we cannot do so at present.

Mr. Whitfield: After the inquest I will renew my application.

The Chairman: Of course you can do so.

Mr. Jubb, recalled by Mr. Whitfield: The accused was not present at the time when the declaration was made.

The Chairman (to prisoner): You stand remanded until Monday.

The majority of the spectators then left the court.

The declaration referred to in the above discussion, though put in as evidence, was not read publicly.

On Friday, September 15th, at noon, an inquest touching the death of Eliza Utley, aged 26, the daughter of Mr. Samson Utley, of Westfield House, Redhill, Greasbro', was opened at the house of the father of the deceased by J. Webster, Esq., district coroner. The death of the deceased was alleged to have been caused by the use, by William Collinson, chemist and druggist, Masbro', of an instrument to procure abortion.

Mr. Edwards watched the proceedings for the prosecution, and Mr. Whitfield attended to watch the case on behalf of the prisoner, who was not present at the investigation.

On Thursday last a *post-mortem* examination of the body was made by Mr. Knight, surgeon, Rotherham; Dr. J. C. Hall, Sheffield; Dr. J. E. Long, of Parkgate; and Dr. Moore, Mr. Knight's assistant.

Mr. Henry John Knight, surgeon, was the first witness called, and gave evidence to the effect that he, in conjunction with the above-named medical gentlemen, had made a *post-mortem* examination of the body of the deceased. He described minutely the appearance presented by the abdomen and other parts. The body was well nourished, but presented indications that the deceased was far advanced in pregnancy. Further investigations showed that there was acute inflammation of the peritoneum, and that the adjacent organs were in an abnormal state, and contained a quantity of watery pus. Mr. Knight then described in detail his examination of those parts of the body the condition of which bore more immediately on the subject of the inquiry. He attributed death to peritonitis, or inflammation of the covering of the abdomen, but declined to swear positively to the immediate cause.

Examined by Mr. Edwards: I am of opinion that there had been an operation. I was shown the body of a male child on Thursday. I take it to be from four and a half to five months old.

In reply to questions by Mr. Whitfield, the witness stated that under certain circumstances indications of violence might not be discovered.

By Mr. Edwards: The instrument produced might be used for other purposes.

Mr. J. E. Long, doctor of medicine, Parkgate (examined by Mr. Edwards): I was called in to see the deceased on Sunday night last, at nine o'clock. I found her suffering very severely from peritonitis. The next time I attended her was on the following (Monday) morning, and I attended her daily. She died on Thursday morning. I should be inclined to believe that she died from peritonitis, as stated by Mr. Knight. On the first occasion of my visit the deceased's mother was in the room, and she afterwards left me there along with the patient. I was with her about three minutes, when Mr. Collinson came up. That was at nine o'clock at night. He made no remarks to the deceased, but I spoke to him first. I said, "Oh, what are you here?" He said "Yes," and I got up from my seat. Mr. Collinson has previously several times practised as a medical man. I asked, "Have you seen this patient?" and he said "Yes." I asked him if he had sent her any medicine, and he said yes, some aperient mixture. He said they (the deceased's parents) sent for him on the previous night, and he saw her that morning. He said he had given her nothing else. I tasted the medicine. He then went away, saying that as I was going to attend the case he would bid me good night. In consequence of something the deceased said to me, I saw Collinson again. I asked him if he had ever seen her before the time he had stated, and he said yes, about three weeks before. I asked him if she had had any medicine, and he said yes, he thought two bottles. I then asked what was the nature of the medicine he had given, and he said each bottle contained two or three drachms of muriated tincture of iron, which is merely a tonic. I then said deceased had had a miscarriage, and he said, "I don't believe that would do it, any way." I then left him, and went to Sheffield. I had no conversation about the paternity of the child. I saw Dr. Hall in Sheffield, and made arrangements with him to attend the case. I have seen Collinson two or three times since Dr. Hall has seen the deceased, and had conversation as to the probable cause of death. I told him Dr. Hall concurred with me in my opinion as to the cause of her death. I was present when she made her declaration before the magistrate, and I went to Mr. Collinson after that. I told him nothing about her stating that he was the father of the child. I told him she made a most serious accusation against him.

In answer to the Coroner, the witness said that the reason he went to Collinson about this case was that the woman told him of it. After the prisoner had left witness on the first night he went to see her, and made a more particular examination.

Cross-examined by Mr. Whitfield: It was on the 12th instant that I told Collinson that the deceased had made the charge against him mentioned in the indictment. The instrument produced might have been used for other purposes.

Mrs. Annie Utley: I am the wife of Samson Utley, miner. The deceased was my daughter. We called her Eliza. She was twenty-six years of age, and a domestic servant. She died on Thursday morning, the 14th instant. I did not know she had had a child. She came home a fortnight to-day (Friday). I was not aware of her state. Collinson has only been to our house twice. I did not know till after she died that she had anything to do with him. I never saw Collinson in my life till he came to my house.

Cross-examined by Mr. Whitfield: Collinson first saw my daughter last Sunday. I sent for him on the previous Saturday night. My daughter was brought home in a cab from Mr. Sharp's house at Rotherham, where she had been attending Mrs. Sharp during her confinement.

Elizabeth Lockwood said: I live at Greasbro'. My father is a collier. I knew Eliza Utley. I saw her at her mother's when she was ill. She was in bed. I followed her directions in certain particulars.

By Mr. Edwards: I did not notice anything at all in it. It was dark at the time. I live with Mr. Utley as servant. I didn't know the deceased was likely to become a mother, and she never told me she was. She appeared to suffer great pain during the day.

William Horne was next called, and said: I live in Rotherham, and am inspector of police in the West Riding constabulary. On Wednesday morning last I took William Collinson into custody on a warrant, which I read to him, charging him with causing the miscarriage of a woman named Eliza Utley by unlawful means. On Thursday morning, the 14th instant, the last witness, Elizabeth Lockwood, pointed out to me an ash heap, which I caused to be emptied. I found the body of a child, and gave it to Dr. Knight.

Mr. Whitfield cross-examined the witness for the defence.

This concluded the evidence, and the coroner addressed the jury as follows:—Gentlemen of the jury, I must not conceal from you the fact that there is a dying declaration made by the woman Eliza Utley. The declaration is here, but it cannot be read, chiefly because there is no one here to prove it. But I think it is only right that you should have that declaration before you if the law will allow it. Therefore I shall adjourn this inquest, in order that I may have an opportunity of looking more fully into the law and seeing whether it can be laid before you; and if so, whether we can have witnesses present to prove that this woman made that dying declaration. We cannot do anything more to-day."

Mr. Edwards: If the jury are satisfied—

The Coroner: I shall not allow the jury to be satisfied. It is a very suspicious case, to say the least of it, and I think we should have all the evidence it is possible to get. The police have done exceedingly well to get the evidence they have in the short time they have had since this matter was brought under their notice.

Mr. Whitfield: Then I think you have got thus far—that the woman had a miscarriage, and that she died from peritonitis.

The Coroner: Yes, and also that she has had some dealings with a man named Collinson, who is charged with procuring abortion; and that I know, and you know, and other people know, that there is that dying declaration.

The inquest was then adjourned until two o'clock next Tuesday, to be resumed at the 'Flying Dutchman,' Parkgate.—*Sheffield Daily Telegraph.*

The adjourned inquest was held at Southgate on the 19th instant.

The evidence of the clerk to the Rotherham bench of magistrates and of a doctor who attended the girl was to the effect that the deceased made a declaration under the impression that she was dying. The declaration stated that she was *enceinte*, William Collinson, chemist and druggist, Rotherham, being the father of the child. She went to him at his shop, and he used an instrument to procure abortion. Subsequently she was prematurely delivered of a dead child. After a consideration of about half an hour, the jury returned a verdict of "Manslaughter." Bail was accepted by the coroner for the prisoner's appearance.—*Times.*

Serious Charge against a Grocer.

John Blowers, grocer, of Weeley, was summoned for having sold, on the 25th August, certain poison, viz. half an ounce of laudanum, the bottle not being properly labelled with the name of the article, the word "poison" and the name and address of the seller, as required by the Pharmacy Act, 1868. Defendant in the first instance pleaded Not Guilty, disputing the quantity named in the summons, but he eventually withdrew that plea.

A child, named Annie Gardener, was put into the box, and the magistrates finding she was not conversant with the nature of an oath (although eleven years of age) she was not sworn. She stated that, on the day in question, she was sent by her mistress to defendant's shop for half an ounce of syrup of poppies, and received from Mr. Blowers the liquid contained in the bottle produced.

Mr. John Tills Lines, by whom the information was laid, stated that on the day in question his wife sent the last witness for half an ounce of syrup of poppies. She returned bringing the bottle and contents produced. The drug was required for family purposes, and witness's wife intended administering a dose to an infant child, but thinking from its appearance and smell that that was not the article she sent for, and seeing a label "tincture of rhubarb" on the bottle she decided not to do so. Next morning, as two other children were suffering from diarrhœa, she decided to use the contents of the bottle for them, but her suspicions of its real nature being again aroused she showed it to witness, and he immediately recognized it as laudanum. He shortly afterwards went to defendant's house and told him of the occurrence, when the defendant said, "Well, syrup of poppies and laudanum are both the same thing, aren't they?"

Witness said, "No, of course they are not."

In answer to Mr. Foaker, defendant said he had no licence to sell drugs. He was not then aware that a certificate was necessary, but he was now. He told the girl it was poison.

The Chairman: That does not affect the case. You had no business to sell drugs without a licence. You ought also to have a book in which to enter all sales of poisons.

Mr. Foaker: The least you could have done would have been to put another label on the bottle. It might perhaps have been left about the house, and there is no telling what the consequences might have been. Mr. Foaker added that there did not seem to him to be half an ounce in the bottle. On being measured in a graduated glass brought by the defendant, it was discovered that there were only two drachms then in the bottle.

In answer to the Chairman, complainant said none had been taken out.

Colonel Hawkins: Then you did not get all you paid for. I think there's something incomprehensible in the defendant not knowing the difference between laudanum and syrup of poppies.

Defendant: That is not a true statement. I have sold drugs all my life, and have never done anything wrong.

Colonel Hawkins: You had no business to sell them at all if you are not properly certificated.

The Chairman: The Excise authorities will see after that. There is a £20 penalty.

Defendant said he had had some correspondence with the Pharmaceutical Society with reference to the case, and had promised not to offend again. He had also expressed his regret to complainant for the occurrence.

After a short consultation with his brother magistrates, the Chairman said the Bench looked upon the present case in a very serious light. They felt it their bounden duty to inflict a heavy penalty, not only for the protection of the public, but to prevent common grocers like defendant from dealing in goods of which they had not a thorough knowledge, and which were so eminently dangerous. Defendant would be fined £5 and 9*s.* expenses, or two months' hard labour.

Defendant applied for time, but, on this being refused, paid the money.—*The Essex Standard and Eastern Counties Advertiser.*

Infringement of the Pharmacy Act.

Mr. Lloyd Rayner, chemist, druggist and dentist, of 309, New North Road, Islington, was summoned by Richard Faulkner to answer the following complaint:—"For that you did, on the 9th day of August last, unlawfully sell certain poison—to wit, oxalic acid—without the cover containing the same being distinctly labelled with the name of the article and the word 'poison,' contrary to the statute."

Mr. Ricketts, solicitor, of Frederick Street, Gray's Inn Road, defended, and, on behalf of the defendant, pleaded not guilty.

These proceedings were taken under the provisions of the Pharmacy Act, 1868, and seemed to create a good deal of interest, the court being well attended by medical gentlemen and others anxious to learn the result.

The complainant deposed that he was a working shoemaker, carrying on business near the defendant. On the 9th of August last he sent his son (a boy about fourteen years of age) to the defendant's shop for one pennyworth of oxalic acid (that being a poison he used in his business for putting a bright red on the heels of ladies' boots). When the boy came back, he was surprised to find that the label on the packet was "effervescent citrate of magnesia" instead of "oxalic acid—poison." About half-past ten on the night of the same day he went to the defendant's shop, and saw the defendant, and asked him if a boy had been to his shop, and purchased one pennyworth of oxalic acid. The defendant told him that there had not; on which he handed him the packet containing the oxalic acid as he had received it from the boy, and asked him if the label with the words "effervescent citrate of magnesia" had been sent out by him. The defendant returned the packet to him, and told him that it was quite possible that some citrate of magnesia had been sold by him, and after remarking that perhaps the contents of the packet had been changed, he said, in an off-hand manner, it was a mistake likely to occur; that it was easy to make such a mistake, as the printer sent in all the labels together, and that sometimes one got mixed with the other. He told the defendant that there was a gross carelessness, and asked him if he would express regret for what had occurred, but as he would not he left the shop. He went a second time to the shop, and saw the defendant, and as the defendant would not apologize he, on public grounds, and for the protection of the public, instituted these proceedings.

Cross-examined by Mr. Ricketts: He had not taken these proceedings with the view of obtaining half the penalty. He had no idea of obtaining any pecuniary advantage from taking out this summons, nor would he have taken money to hush up these proceedings. All he wanted was for the defendant to apologize, and if that had been done by the defendant there would have been an end to the matter.

Frederick Faulkner, the son of the previous witness, deposed that he purchased the packet produced at the defendant's shop, and that he handed it to his father in the same state as he received it from the defendant.

Mr. Thomas Jones, surgeon, of 5, York Place, Islington Green, said the packet produced and its contents had been brought to him for analysis, and he had ascertained that it was oxalic acid, a poison.

In answer to Mr. Ricketts, the witness said he had made several tests, and they all showed that the poison was oxalic acid. There was not enough in the packet to poison any one.

By Mr. Cooke: There was quite enough in the packet to kill a child. Of course oxalic acid ought not to be carelessly sold.

Mr. Ricketts, on behalf of the defendant, entirely repudiated the sale of the poison, but after the sworn testimony of the complainant he was bound to admit that if it was sold at the defendant's shop, a wrong label must have been put on the packet. It was no uncommon thing for the labels to get mixed before they came into the chemist's possession; but this was not a case of neglect, for the defendant labelled everything that left his shop. His client looked at the complainant's visit to him as an attempt to extort money from him by threats, and that looked very much like a fact, for he (Mr. Ricketts) was instructed that the complainant told the defendant that he had been advised by some neighbouring—some rival—chemist to take these proceedings.

Several medical gentlemen of standing in the profession were called, who gave the defendant an excellent character for the past fourteen years, and said he was one of the most careful prescribers of medicine they had ever known.

Mr. Ricketts having remarked that citrate of magnesia and oxalic acid were very much alike, with the permission of the magistrate asked the complainant if he had not threatened to expose the defendant in the public newspapers, and was answered in the negative.

Mr. Cooke said that it was very much to be regretted that the defendant, a chemist and druggist, with such a high character as he had received, should have sent out such a poison as that of oxalic acid with a label on it that it was citrate of magnesia, and in ignorance of whether it was so or not. He should not be doing his duty if he did not inflict the highest penalty, which was £5, or in default two months' imprisonment in the House of Correction.

The fine was at once paid.—*Daily News.*

Obituary.

MR. JOHN DUNCAN.

About three o'clock on Wednesday morning, Sept. 13, Mr. John Duncan, of the firm of Messrs. Duncan and Flockhart, 52, North Bridge, and 139, Princes Street, Edinburgh, died at his house at Burnhead, Liberton. The deceased was, at the time of his death, in his ninety-second year, and had during his lifetime enjoyed the esteem of a large circle of friends. As a chemist, Mr. Duncan was widely known. Sixty years have elapsed since he first occupied the present premises of the firm on the North Bridge; and he was in business at Perth for some time before he came to Edinburgh.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

VACANCIES.

Dispenser of Medicines and Head Nurse in the male infirmary of the Manchester workhouse at Crumpsall. Applicants are to be unmarried men, not less than thirty years of age; salary, £30 per annum, with board, washing and lodging. Particulars of the duties may be obtained from Mr. Wharf, Master of the Workhouse. Applications in the handwriting of the candidates, stating age and occupation, and enclosing testimonials as to character and fitness for the situation, must be sent to John Harrop, Clerk to the Guardians, at his office, New Bridge Street, Manchester, not later than 10 A.M. on Thursday, the 28th instant, marked outside "Dispenser," etc.

Dispenser at the Greenwich Union. Salary £80 per annum, with unfurnished apartments, coals, and gas, but without rations. Candidates must be between the ages of twenty-two and forty, and must be Licentiates of the Apothecaries' Company of London, or duly registered under the Pharmacy Act, 1868. Applications, accompanied by testimonials and a statement of qualifications, to be sent before Thursday the 28th, to Samuel Shaw, Clerk to the Guardians.—Union Offices, Woolwich Road, Greenwich, 7th September, 1871.

The following journals have been received:—The 'British Medical Journal,' Sept. 16; the 'Medical Times and Gazette,' Sept. 16; the 'Lancet,' Sept. 16; the 'Medical Press and Circular,' Sept. 20; 'Nature,' Sept. 14; the 'Chemical News,' Sept. 15; 'English Mechanic,' Sept. 15; 'Gardeners' Chronicle,' Sept. 16; 'Chemist and Druggist,' Sept. 15; the 'Grocer,' Sept. 16; the 'Journal of the Society of Arts,' Sept. 15; the 'Canadian Pharmaceutical Journal,' No. 2; the 'American Journal of Pharmacy,' No. 9; 'Sheffield Telegraph;' 'Rotherham and Masbro' Advertiser.'

Correspondence.

PHARMACEUTICAL NOMENCLATURE.

Sir,—Your last number contains some remarks by Mr. C. R. C. Tichborne on my recent paper "The Chemical Nomenclature of the Pharmacopœia." Mr. Tichborne concurs in nearly all I have written on the subject, and gives a support which is the more valuable, because coming from a thoughtful and zealous worker in pharmacy as well as in chemical science, one whose foresight fourteen years ago detected the importance of the ideas embodied in modern chemical notation and nomenclature; on a single point my friend seems to differ from me. He appears to dissent from my proposition that "the time has come when, by making a few slight alterations in the terminal syllables of some of our chemical names, we shall have a system of pharmaceutical nomenclature which, while perfectly harmonious with, is quite independent of, scientific chemical nomenclature, and which, therefore, contains greater elements of permanence than any yet adopted." He says, "A nomenclature is only a system for the conveyance of facts." It is not to be supposed that we could have two nomenclatures harmonizing equally, if at all, with facts. As well might we state that pharmacy should have an arithmetic of its own, and that 1 and 1 in mathematics should make 2, but in pharmacy they should make 3. Now, Sir, I beg to apologize to you and to him for employing the following phraseology, but, respecting this sum in simple addition, I really must ask the gentleman who signs himself C. R. C. Tichborne if he would be surprised to learn that the writer entirely agrees with him? Indeed, with regard to the matter of which this sum is an illustration, perhaps that very intelligent jury, your readers, will not be astonished when I tell them that the claimant to the above name and the undersigned entirely agree with each other. Let us see. Here are examples of the old set of names:—

THE OLD NOMENCLATURE.

Nitrate of potash.
Phosphate of soda.
Sulphate of magnesia.

These names are no longer used in chemistry, because they do not represent chemical truth so far as it is now known, and as it is now being taught to the men who will in a few short years succeed the pharmacists of the present day. Followers of modern chemistry, including Mr. Tichborne and myself, are unanimous in discarding this old system, and in following the new.

THE NEW NOMENCLATURE.

Variety 1.

Nitrate of potassium.
Phosphate of sodium.
Sulphate of magnesium.

Variety 2.

Potassium nitrate.
Sodium phosphate.
Magnesium sulphate.

Variety 3.

Potassic nitrate.
Sodic nitrate.
Magnesic sulphate.

Here is the point. What I have just called Variety 1 of the new nomenclature is alluded to in my proposition as a distinct system of pharmaceutical nomenclature,—a way of putting the matter which, I must admit, is liable to mislead, and which has misled Mr. Ince and Mr. Tichborne, and possibly other friends. From what I now write, it will be obvious that what I advocate is not one distinct system of chemical nomenclature for pharmacy and another for scientific chemistry, but that in pharmacy and medicine one of the current modifications (Variety 1) of the new chemical nomenclature should exclusively be employed,—the one supported by Mr. Tichborne.

May I be allowed to add two remarks, the one fairly pertinent, the other just a trace impertinent. The first is, that the proposed system of pharmaceutical nomenclature—or, *pace* Tichborne, the selected modification of the new chemical nomenclature—may be adopted by even the grey-haired without one backward step towards school, nay, without an effort. The second is, that the medical practitioner and the pharmacist may as well adopt the method at once, for *nolens volens* the new will certainly displace the old, and while prescriptions are written in Latin no other variety of the new is possible.

I hope you will not consider this explanation uncalled for and unworthy insertion, because, like most explanations, arguments and controversies, it ends in a mere definition of terms. I know, too, that I am riding a hobby, and trust that the nag's present healthy circulation will thereby be maintained. The proposal to adopt this form of chemical nomenclature in future editions of the Pharmacopœias of all countries has hitherto met with nothing but encouragement. I am anxious that not even an apparent objection to the system should remain unanswered.

JOHN ATTFIELD.

THE COUNCIL OF THE NORTH BRITISH BRANCH OF THE PHARMACEUTICAL SOCIETY.

Sir,—Mr. Fairlie writes in his last letter, "Having hitherto received nothing but kindness at the hands of our Edinburgh brethren, we only wish that good feeling will continue to be reciprocated between us."

This is in strange antagonism with Mr. Fairlie's ungenerous attack upon those from whom he has received "nothing but kindness," and who have had the most harmonious intercourse hitherto with our friends in Glasgow, not only with those who have attended our meetings, but also with those who have been unable to attend.

Mr. Fairlie implies, if he does not absolutely assert, that the members of Council of the North British Branch are personally benefited by the money obtained from London for the necessary expenditure connected therewith. Having so recently become a member, Mr. Fairlie is probably not aware that for twenty-eight years Mr. John Mackay gave an amount of time and thought in the interest of the Society as Honorary Secretary, without receiving any remuneration whatever, thus saving the parent Society a very large sum, had a paid Secretary been employed, which must otherwise have been the case; and but for his untiring exertions in the earlier years of the Society's existence, pharmacy—in Scotland, at least—would have been in a very different condition to what it now is. Every sixpence of the very moderate amount received has been expended in the interest of the Society and, as Mr. Mackay points out, the Library and Museum (inadequate as they are) belong to the Pharmaceutical Society of Great Britain, and no member of the Council here ever received the slightest remuneration for his time and services. One and all have had but one object in view—the advancement of pharmacy throughout Scotland.

In conclusion, I cannot but regret that Mr. Fairlie was not earlier a member of the Society, when* "he would have known of many a hard-fought battle, of many an anxious hour, of difficulties to surmount, prejudices to overcome in the unflinching desire that name and position should be obtained" for pharmacy in Scotland.

Edinburgh, Sept. 13*th*, 1871. H. B. BAILDON.

Sir,—I cannot refrain from protesting, not only against the columns of our scientific Journal being taken up with such excessively personal attacks on members of our body, but more particularly that old and valued men amongst us should feel themselves called upon to spend their time and patience in inditing lengthy epistles in vindication of acts done in their official capacity, which, but for the violent tirades of some would-be agitator, should never be called in question. I am sure, Sir, you will agree with me, that it is quite time a limit should be put on the "liberty of the subject" in this matter, and enter your protest with mine in the next Journal.

WILLIAM HARTLEY.

7, *Church Street, St. Andrew's, September* 13*th*, 1871.

* See PHARM. JOURN. Vol. XI. 2nd series, p. 25.

Sir,—In the last number of your Journal, "One who has Passed" asks for information, which I will gladly give.

Until recently the Board of Examiners have had a distinct and separate set of questions printed for the Preliminary, but, with a view to render these meetings as like those in London as possible, they have lately adopted the same sheet as the Board in the metropolis. To prevent, however, a recurrence of what your correspondent has pointed out, I may here mention that it has now been arranged, on and after the 1st of January, 1872, to hold all the Preliminary Examinations in London, here and in the provinces on the same day, and submitting the same questions as in Bloomsbury Square. The effect of this will be, that in future only *four* opportunities will be given for the First or Preliminary Examination throughout the year, and these will, on every occasion, be simultaneous.

JOHN MACKAY.

Edinburgh, Sept. 18*th*, 1871.

THE CHIPPENHAM CASE.

Sir,—I am delighted at the delicate attention M. P. S. has been good enough to pay me, and for speaking in such gentle terms of my practice. In commenting upon the application of a solution of bichloride of mercury made by Dr. Meeres to the head of a little child for the cure of ringworm, M. P. S. asks, "Who amongst the trade of chemists, whether apprentice of twelve months' standing or assistant, would think, for one moment, of using a thing so powerful and caustic to the head of a child?" I am so glad to find M. P. S. has such a correct sense of the proper duties of the pharmaceutist, and such a keen appreciation of the importance of the chemist not usurping the duties of the medical practitioner. M. P. S. does not presume, does not wish in fact, to set himself up as a judge of therapeutics as against properly qualified physicians. But, Sir, unfortunately I acknowledge that I have been "ignorant enough" to make use of such "outrageously strong" applications as that employed by Dr. Meeres very freely and very frequently for thirteen or fourteen years without the shadow or vestige of a mishap or evil consequence, and only with unvarying success.

If M. P. S. will turn to either of the medical journals of last week, he will see that, without exception, they say that Dr. Meeres has been most unjustly condemned, and that the sad result of his treatment is to be attributed to an unfortunate idiosyncrasy in the patient against mercury, and could not have been foreseen. M. P. S. compares a case of poisoning with a case of unforeseen accident. In the one case there was an absolute blunder; in the other, an untoward result from the use of a well-known remedy by the hands of one who had used it according to authority, and not for the first time, but as an old acquaintance. No parallel between the two cases is possible.

Before M. P. S. takes upon himself to "bell the cat" again he should be sure that she deserves it.

TILBURY FOX, M.D., F.R.C.P.

Sackville Street, W., Sept. 18*th*, 1871.

[*** We appreciate Dr. Fox's emotion at being associated ever so remotely with a case of poisoning, even under medical auspices, and we fully agree with him in thinking the jury exceeded its functions in censuring Dr. Meeres for using an application according to authority, whatever may be the value of the opinion that it could not do harm. At the same time it is evident that the application was capable of poisoning, even when so used, and though we do not endorse the parallel drawn between the Chippenham and Salcombe cases, "M. P. S." is not alone in thinking that somewhat greater care might have rendered Dr. Fox's hypothesis of "idiosyncrasy" superfluous.—ED. PHARM. JOURN.]

TINCT. KINO AND TINCT. KRAMERIÆ.

Like many others of my Pharmaceutical brethren, I have been much inconvenienced by the perverse behaviour of tincture of kino. At the time I made my last batch, now about two years ago, the idea occurred to me to use the kino in the coarsely granular state in which we receive it, instead of first powdering it; the result proved quite successful, the tincture being as fluid now as when first made. When maceration was complete, I poured off the clear tincture, washed the dregs with a little sp. vini rect. and turned the whole on to a muslin cloth, poured a little more spirit over, and gently squeezed it with the fingers, afterwards adding more spirit to make the required measure. I now discovered that each particle of the gum retained its individuality, if I may so term it, much paler in colour, slightly swollen, and in the condition of a very stiff jelly, which crumbled when rubbed between the fingers.

The batch preceding this, of which I write, was made from the same parcel of gum, but first reduced to a finer state of division; the tincture soon gelatinized and had to be thrown away. This experience, therefore, would tend to show that the state of division does influence the keeping of the tincture.

A short time since having to replenish my shop-bottle of tinct. krameriæ from the stock in the cellar, where it had reposed undisturbed for a long time, I found to my surprise that it had assumed the gelatinous condition. I never heard of such an alteration taking place in tinct. krameriæ, and cannot help thinking it unusual; perhaps some of your correspondents may be able to enlighten us?

Liverpool. J. H. HUSTWICK.

TINCTURE OF KINO.

Sir,—Referring to the notices which have recently appeared in the Journal on the gelatinization of tincture of kino, I beg to state that for several years I have added a small quantity of glycerine, and that I have found so small a quantity as 5 drms. to the pint quite sufficient to preserve it in a fluid state. This, I submit, is an excusable addition to the authorized formula, and an easy remedy.

Ludlow, September 2*nd*, 1871. GEORGE COCKING.

DRUGGISTS' PRICES.

Sir,—We read in the PHARMACEUTICAL JOURNAL about prices in the north; can they be surpassed by the following, which I am assured by a venerable clergyman to have been dispensed for *sixpence*—bottle included—by a Pharmaceutical Chemist in this town:—

℞. Potass. Bicarb. ʒij
Sp. Æth. Nit. ʒij
Tinct. Hyoscyam. ♏xviij
Tinct. Opii ♏xviij
Aquæ Puræ ad ℥vj.
Ft. mist.

High Street, Grantham. W. M. BETTS.

Registered Student.—Fresenius is most complete.

G. L. Napier.—Your suggestion is a good one, but since the case will be publicly investigated, it would be improper to interfere now.

Wm. Gill.—Communications are always acknowledged, but not necessarily for acceptance or rejection. The subject of poison bottles has, we think, been more than exhausted.

H. B. Crofts should communicate with the publishers.

Pharmaceutical Education in the Provinces.—We have received several letters on this subject, in which the want of provincial schools of pharmacy is dwelt upon or suggested, and, among others, some letters from Edinburgh complain that the prize lists of the Pharmaceutical Society contain only names of men who have studied in London, none of those who have passed the Major or Minor Examinations with honours in Scotland being represented. Our correspondents, reasonably enough, say they are not surprised that this is the case, but they justly complain that they have not the opportunities of the London students. This subject is one of especial importance at the present time, and it is only because we purpose shortly to speak of it more fully that we refrain from publishing our correspondents' letters at present.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Wilkinson, Messrs. Kay Brothers, Mr. H. B. Croft, Mr. H. Crabb, "Scribo."

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 181.)

Several species of *Mylabris* inhabit the Cape of Good Hope besides those already enumerated as common also to Asia. It is uncertain whether these or any of them are locally employed as vesicants. The following are the principal:—

M. Lavateræ, Fabr.; hairy, black; elytra shining, spot at the base, and two subequal broad bands, paled vermilion.—Billb. Mon. t. 1. f. 7. *M. pustulata*, var., Oliv. Ent. iii. t. i. f. 1 *f*; Rœm. Gen. Ins. t. 7. f. *a*.—This is a large insect, and most probably employed.

M. quadrifasciata, Thunb.; hairy, black; elytra black, with four yellowish-white bands, the second interrupted, and the third dentate.—Billb. Mon. t. 2. f. 4–8; Thunb. N. Sp. f. 18.

M. Gyllenhali, Billb.; villous, black; elytra black, with seven ochraceous spots, the last nearly at the extreme apex.—Billb. Mon. t. 2. f. 9–11. *M. variabilis*, Oliv. Ent. iii. t. 2. f. 14 *a*.

M. tripunctata, Thunb.; villous, black; elytra yellowish or flesh-coloured, with three points, an arched band behind the middle, and the apex black. —Thunb. Sp. Ins. vi. p. 112; Billb. Mon. t. iii. f. 14–16.

M. cocca, Thunb.; villous, black; elytra rugose, brick-red, with four punctate black bands, interspaces maculæform.—Thunb. N. Sp. vi. f. 11, 12; Billb. Mon. t. iv. f. 6–9.

M. capensis, Fabr.; villous, black; elytra black, with six yellow spots, that on the shoulder arcuate. —Oliv. Ent. iii. t. 2. f. 12; Billb. Mon. t. iv. f. 11; Wulf, Ins. Cap. t. i. f. 5 *a*, *b*; De Geer, Mem. vii. t. 48. f. 14.

M. undata, Thunb.; villous, black; elytra black, with two waved yellow bands, and an uncinate spot next the scutellum.—Thunb. N. Sp. vi. f. 17; Billb. Mon. t. iv. f. 16, 17. *Canth. undatofasciata*, De Geer, Mem. vii. t. 48. f. 15, 16.

M. sexdecimguttata, Thunb.; villous, black; elytra black, with eight yellowish spots, the three last confluent.—Thunb. Sp. Ins. vi. f. 20; Billb. Mon. t. v. f. i.

M. quadriguttata, Wulf; hairy, black; elytra black, with six yellowish spots, of which the two last are almost confluent.—Wulf, Ins. Cap. t. 1. f. 7 *a*, *b*; Billb. Mon. t. v. f. 3, 4.

M. decemguttata, Thunb.; villous, black; elytra black, with five rounded yellow spots, of which the one in the foremost angle is linear.—Thunb. N. Sp. vi. f. 19; Billb. Mon. t. 5. f. 5.

M. flavicornis, Fabr.; villous, black; elytra black, with three tawny bands, and two spots at the apex. —Billb. Mon. t. vi. f. 3.

M. lunata, Fabr.; villous, black; elytra black, with an ochraceous lunate spot at the base, and two bands of the same colour, narrowed towards the margin.—Oliv. Ent. iii. t. i. f. 2 *a*, *b*; Billb. Mon. t. vi. f. 4–7; Thunb. N. Sp. vi. f. 15; Pall. Icon. t. E. f. 5 *a*, *b*. *M. americana*, Herbst. Arch. t. 30. f. 5. *Meloe cichorii*, Wulf, Ins. Cap. xvii. t. i. f. 4 *a*, *b*; f. 6 *a*, *b*; f. 3 *a*, *b*.—This is another large insect available for medicinal purposes.

M. Africana, Oliv.; villous, black; elytra rather tawny, with two discoidal spots, and two in common at the suture, the base of the suture, and the apex black.—Oliv. Ent. iii. t. 2. f. 21; Billb. Mon. t. vi. f. 8. *Meloe 10-punctata*, var. *a*, Thunb. N. Sp. f. 7.

All of these possess vesicatory properties there can scarcely be any doubt, but we have not been able to learn whether any of them have been so employed. Other species occur in other parts of Africa, and elsewhere in the Old World, to which we need not specially refer, as they are rather of entomological than pharmacological interest.

Allied to *Mylabris*, and placed by entomologists in the same group, is *Cerocoma*, of which one species is employed.

SCHÆFFER'S CEROCOMA, *Cerocoma Schæfferi*, Fabr.; green, antennæ and feet yellowish.—Fabr. Syst. El. ii. p. 71; Panz. 96, f. 11; Schæff. Icon. t. 53, f. 8, 9; Moq.-Tand. Med. Zool. p. 135, fig. 33. *Meloe Schæfferi*, Linn. Syst. ed. xii. p. 681. *Cerocoma viridis*, Fourc. Ent. Par. p. 163.

This insect is from five to seven lines in length. It is minutely pubescent, and of a golden green colour; the head is small, and with the thorax of a darker colour. The antennæ and feet are tawny-yellow. The elytra are the same length as the abdomen and very flexible.

It lives on composite and umbelliferous plants in most parts of Europe, especially the south, burying itself amongst the flowers, and is an active flyer.

Moquin-Tandon includes this amongst the few vesicants enumerated by him in his medical zoology.

There are several other species belonging to the same genus found in France, Spain and the East, but their vesicatory properties have not been investigated.

Part IV. EUROPEAN CANTHARIDÆ.

The second family of vesicants contain the *Cantharidæ*, and the few European species belong to two genera, *Lydus* and *Lytta*. The former of these includes two species, both of which were at one time classed with *Mylabris*, and will now serve as a link to unite the Chinese flies and their allies to the European blistering-fly and its associates. We need not enter here upon the technical characters and distinctions of these genera.

IMMACULATE LYDUS, *Lydus Algiricus*, Mars.; subvillous, black; elytra tawny or brick-red, unspotted.—Mars. Mem. Lyons, 1858. p. 133. *Mylabris Algirica*, Fabr. Syst. El. ii. p. 28; Oliv. iii. T. i. f. 5; Billb. Mon. t. vii. f. 11. *Meloe Algirica*, Linn. S. N. xii. p. 651. *Lytta Indica*, Herbst, Arch. vi. p. 147, t. 30. f. 3.

Fig. 5.—*Lydus Algiricus.*

Head yellowish, somewhat hairy, black, punctate. Thorax scarcely longer than broad, yellowish, somewhat hairy, black, punctate. Scutellum black, punctate. Elytra more than three times as long as broad, tawny, brick-red, or pale testaceous, immaculate. Breast and abdomen black, with yellowish down punctate. Feet black, somewhat hairy.

Native of Italy and Africa. As far as we can judge this is the species which Moquin-Tandon alludes to (Med. Zool. p. 137) under the name of *Meloe Algeria*, L., which inhabits Sardinia, and which, he states, has been recommended as a vesicant. There is no doubt of its possessing vesicatory properties, and where sufficiently abundant would be no bad substitute for the green fly.

THREE-SPOTTED LYDUS, *Lydus trimaculatus*, Fabr.; black; elytra tawny, with three black spots.—Fisch. Ent. Russ. ii. t. xli. f. 5, 6; Brandt and Ratzb. ii. t. xviii. f. 16. *Mylabris trimaculata*, Billb. Monog. Myl. t. 6, f. 15. *Cantharis trimaculata*, Oliv. Ent. iii. t. 2. f. 19.

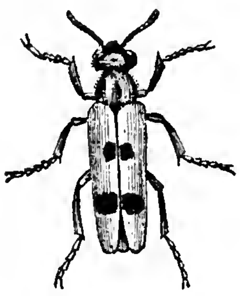

Fig. 6.—*Lydus trimaculatus.*

Head black, somewhat hairy, punctate, transversely depressed in front. Thorax somewhat hairy, black, punctate, a little longer than broad. Scutellum black, punctate. Elytra three times as long as broad, roughly punctate, with four elevated lines, tawny, the spot behind the middle discoid, or fasciate and abrupt at the suture and margin; the spot before the middle confluent at the suture, as if it were one cordate spot. Breast and abdomen black, punctate. Feet black.

Inhabits the north of Europe, where, according to Professor Westwood, it is employed as a vesicant. It is one of the species included by Brandt and Ratzeburg in their 'Medical Zoology,' though it seems to be limited in its use. This, as well as the preceding, was formerly classed with *Mylabris*, to which it is closely allied. It is the *Mylabris trimaculata* of some pharmacologists.

(*To be continued.*)

THE PROPERTIES OF INULINE.

BY DR. K. TRANTL.

The philosophical faculty of the University of Munich offered, for the year 1869–70, a prize for the best investigation on inuline, its sources, properties, and physiological value, together with a critical review and enlargement of these statements based upon original investigation. Dr. Trantl has gained the prize by an exhaustive work, a short outline of which will here suffice to draw attention to the original.

The inuline was prepared from the root of *Inula Helenium* and from the tubers of *Dahlia variabilis*, the last being easily obtainable in large quantities, and yielding a considerable percentage; the roots were coarsely powdered and heated with an equal volume of water, and a small quantity of carbonate of lime to neutralize organic acids; the extraction was repeated with fresh portions of water till the liquid did not become turbid with alcohol. The decoctions are always turbid from coagulated albumen and fragments of membrane; they are allowed to stand for some time, the liquid poured off from the sediment and evaporated till a skin is formed on the surface. In about 24 hours the liquid solidifies to a thick brown magma, and, on addition of water, the inuline separates as a yellowish-white powder, and is finally purified by dissolving it in much water, boiling with charcoal, filtering and evaporating, when it is separated as a perfectly white powder, which is dried first at 50° C., and ultimately at 120° C.

Inuline, thus prepared, consists of microscopically small globules of different sizes, without smell or taste; heated to 165° C. it becomes viscid, slightly brown, and solidifies on cooling to a gummy mass, which dissolved in cold water separates in two layers on addition of alcohol, one unchanged inuline, insoluble in alcohol, the other a yellowish-brown fluid, leaving, on evaporation, a brittle, gummy substance of very sweet taste; it is readily soluble in cold water and in alcohol, and does not reduce Fehling's copper solution. Dr. Trantl named this substance pyroinuline; Payen takes it as isomeric with inuline, as his analysis gave the formula $C_{12}H_{10}O_{10}$.

In contact with water inuline gives a milky liquid, which, on evaporation, leaves scarcely any residue; but on heating, it becomes clearer, and, according to the degree of heat, is dissolved, as shown in the following table, viz.:—

100 c. c.	saturated at	0° C.	contained	0·01	gram inuline.
,,	,,	14°	,,	0·02	,,
,,	,,	30°	,,	0·27	,,
,,	,,	60°	,,	1·57	,,
,,	,,	80°	,,	4·00	,,
,,	,,	100°	,,	36·50	,,

Inuline forms a real solution, not merely a pastelike starch, and it may be obtained from the solution in spheroidal crystals; alcohol does not dissolve it, as erroneously stated in several books, it is also insoluble in ether, bisulphide of carbon, and in essential and fatty oils.

Concentrated sulphuric acid first makes the grains transparent, and then dissolves them, and continued action carbonizes it; dilute sulphuric acid readily changes it into grape sugar.

Concentrated phosphoric acid carbonizes the inuline, and dilute acid acts similarly to dilute sulphuric acid.

Nitric acid readily dissolves inuline in the cold, but on dilution no explosive compound is precipitated as with starch.

Many other reactions are given by the author, mostly confirming previous observations of Payen, Schacht and others.

The author deduces from his investigation the final result that inuline cannot be compared with starch or cellulose, and from dextrine it differs by its stability, but it is nearest allied to cane-sugar.

Dr. Trantl comes next to the condition in which inuline exists in the root: analysis showed that the roots contained a pretty strong solution, viz. 10·7 per cent. to 77·7 per cent. of water, a concentration which cannot be obtained by a solution without separation of inuline on cooling; and after several unsuccessful experiments to explain this solubility in the plant itself, the author assumes that inuline in the cell-sap exists in a different modification which is more soluble in cold water, and which once separated goes over into the less soluble modification. The exhaustive treatise concludes with a very lengthy list of plants which contain inuline.—*Buchner's Repert. für Pharm.* 1870, ix. p. 513, and x. p. 577.

ADULTERATIONS OF BROMIDE OF POTASSIUM.

BY M. ADRIAN.

Ten samples of bromide of potassium obtained from the principal French manufacturers were analysed, and only one of them was found sufficiently pure for medicinal purposes; the others contained from 10 to 15, one sample even 35 per cent. of impurities. Similarity in form of crystallization of bromide, iodide and chloride of potassium makes a superficial inspection impossible, and one sample, remarkable for the whiteness, thickness and regularity of its crystals, was found to be extremely impure.

All samples contained moisture, from ½ to 4½ per cent., and free alkali or carbonate, from 1·5 to 4·25 per cent.; three samples contained iodide of potassium ½ to 2 per cent.; nine samples contained chloride of potassium, some 11·15 and 30 per cent., also sulphate of potash 1 to 3 per cent. Traces of bromate of potash were found in three samples, and appreciable quantities only in one. M. Adrian is of opinion that this is a very dangerous impurity, inasmuch as it may give rise to the elimination of bromine in the stomach and be the cause of violent inflammation of the bowels.

Bromide of potassium is prepared by passing chlorine through the mother-lyes of certain salt-works containing bromide of calcium and magnesium, together with iodides; the mother-lyes, coloured intensely yellow by free bromine, are shaken up with ether, the solution treated with potash, the bromate of potash which is formed, together with the bromide, is converted into bromide by ignition, dissolved in water and separated by crystallization. If chlorine is now passed through the mother-lyes, it not only replaces bromine and iodine in its compounds, but it unites with it to form chloride of bromine and iodine, which are both soluble in ether. This ethereal solution treated with potash, which frequently contains considerable quantities of chloride and sulphate, must of course yield a very impure article.

The impurities are best recognized by dissolving ten grams of the salt to 100 c. c. solution; effervescence on addition of hydrochloric acid proves the presence of carbonates; one drop of benzole and a few drops of bromine water produce a rosy colour if iodides are present; sulphate is detected by nitrate of baryta, and bromate by sulphuric acid producing a yellow coloration. After these preliminary tests and after complete separation of the carbonate, sulphate and iodide, the chloride may be determined by a standard solution of silver.—*Journ. de Pharm. et de Chim. janv.* p. 17.

PROTOPLASMIC LIFE.*

BY F. CRACE-CALVERT, F.R.S.

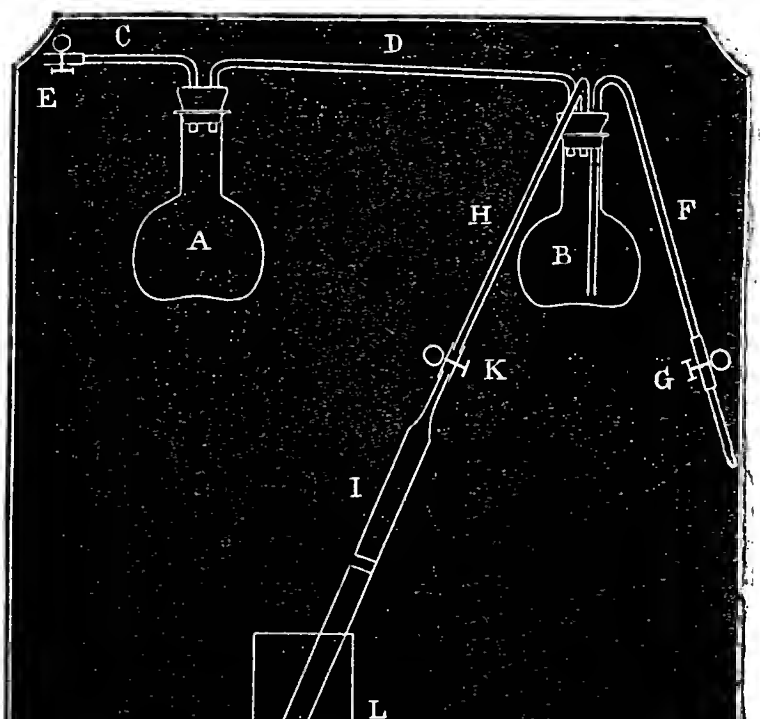
A year since, the publication of Dr. Tyndall's interesting paper on the abundance of germ-life in the atmosphere and the difficulty of destroying this life, as well as other papers published by eminent men of science, suggested the inquiry if the germs existing or produced in a liquid in a state of fermentation or of putrefaction could be conveyed to a liquid susceptible of entering into these states; and although at the present time the results of this inquiry are not sufficiently complete for publication, still I have observed some facts arising out of the subject of protoplasmic life which I wish now to lay before the Royal Society.

Although prepared, by the perusal of the papers of many workers in this field, to experience difficulties in prosecuting the study, I must confess I did not calculate on encountering so many as I met, and especially those arising from the rapid development of germ-life, and of which I have hitherto seen no notice in any papers which have come under my observation. Thus, if the white of a new-laid egg be mixed with water (free from life), and exposed to the atmosphere for only fifteen minutes in the months of August or September, it will show life in abundance. From this cause I was misled in many of my experiments, not having been sufficiently careful to avoid momentary exposure of the fluids to the atmosphere. To knowledge of this fact may be traced the erroneous conclusions arrived at by several gentlemen who had devoted their attention to the subject of spontaneous generation.

I believe that I have overcome the difficulty of the fluids under examination becoming polluted by impregnation by the protoplasmic life existing in the atmosphere, by adopting the following simple method of working.

As a pure fluid, free from life and having no chemical reaction, was essential to carrying out the investigation, I directed my attention to the preparation of pure distilled water. Having always found life in distilled water prepared by the ordinary methods, by keeping it a few days,—after many trials I employed the following apparatus, which gave very satisfactory results, as it enabled me to obtain water which remained free from life for several months.

It consists of two flasks, A and B (A rather larger than B), fitted with perforated caoutchouc stoppers.* These flasks are connected by the tube D. Into the stopper of A is fitted a tube C, to which is joined a piece of caoutchouc tubing, which may be closed by the clip E. Through the stopper of B is a siphon, F, the long limb of which is cut and joined with caoutchouc tubing, which can be closed by the clip G. Through this stopper is a third tube, H, connected by caoutchouc with



the tube I; this can be closed by the clip K. The tube I is about three feet long and goes into the vessel L, which is partly filled with water.

The water to be distilled is mixed with solution of potash and permanganate of potash and placed in the flask A.† Before distillation is commenced, a rapid current of pure hydrogen or some other gas, must be passed through the apparatus by the tube C to displace

---

* From the Proceedings of the Royal Society, No. 128, 1871.

* The stoppers and caoutchouc tubing used for the various joints must be new, and must be well boiled in water before use.

† The reasons why I employed permanganate of potash (in large excess) were that, under the influence of heat, its oxidizing powers were much increased, and that it gave off no gas that could interfere with the purity of the water, this salt in solution not even yielding oxygen under any circumstances.

the air and carry off all the germs the air may have contained. The clip G is first left open, then this closed and the clip K opened, which allows the gas to through the water in the vessel L. for about fifteen

The gas should be passed closed and the distillation minutes. The clip The operation is complete, the gas carried on again passed through the apparatus, and the connection with the tube I broken by closing the clip K. The water is drawn off through the siphon F. The long tube acts as a safety-tube, and is made so long that the absorption is noticed in ample time to close the clip before any air can enter through that tube.

The water has to be redistilled three or four times before it is obtained free from germs, and must be kept in the apparatus in which it is distilled until wanted, to prevent any contact with air.

Some water which had been distilled on the 20th of November, 1870, being still free from life on the 7th of December, was introduced by the siphon H into twelve small tubes, and left exposed to the atmosphere for fifteen hours, when the tubes were closed. Every eight days some of the tubes were opened and their contents examined. On the fifteenth, therefore, the first examination was made, when no life was observed; on the twenty-third two or three other tubes were examined, and again no life was detected; whilst in the series opened on the 2nd of January, 1871 (that is to say, twenty-four days from the time the tubes were closed), two or three black vibrios were found in each field.

Being impressed with the idea that this slow and limited development of protoplasmic life might be attributed to the small amount of life existing in the atmosphere at this period of the year,* a second series of experiments was commenced on the 4th of January. The distilled water in the flask being still free from life, a certain quantity of it was put into twelve small tubes, which were placed near putrid meat at a temperature of 21° to 26° C. for two hours, and then sealed. On the 10th of the same month the contents of some of the tubes were examined, when two or three small black vibrios were observed under each field. This result shows that the fluid having been placed near a source of protoplasmic life, germs had introduced themselves in two hours in sufficient quantity for life to become visible in six days instead of twenty-four. Other tubes of this series were opened on the 17th of January, when a slight increase of life was noticed; but no further development appeared to take place after this date, as some examined on the 10th of March did not contain more life than those of the 17th of January.

This very limited amount of life suggested the idea that it might be due to the employment of perfectly pure water, and that the vibrios did not increase from want of the elements necessary for sustaining their life. I therefore commenced a third series of experiments. Before proceeding to describe this series, I would call attention to the fact that the water in the flask had remained perfectly free from life up to this time, a period of close on sixteen weeks.

On the 9th of February 100 fluid grains of albumen from a new-laid egg were introduced, as quickly as possible and with the greatest care, into 10 ounces of pure distilled water contained in the flask in which it had been condensed, and an atmosphere of hydrogen kept over it. On the 16th some of the fluid was taken out by means of the siphon H, and examined, and, no life being present, twelve tubes were filled with the fluid, exposed to the air for eight hours, and closed. On the 21st the contents of some of the tubes were examined, when a few vibrios and microzyma were distinctly seen in each field. On the 27th other tubes were examined, and showed a marked increase in the amount of life. In this series life appeared in five days, and an increase in ten, instead of requiring twenty-four days, as was the case when pure water only was employed.

Albumen therefore facilitated the development of life. Of course the contents of the flask were examined at the same time, but in no instance was life detected. I believe that these three series of experiments tend to prove the fallacy of the theory of spontaneous generation; for, if it were possible, why should not life have appeared in the pure distilled water, or in the albuminous solution, which were kept successively in the flask B, as well as in the fluids which were contained in the tubes, and had been exposed to the atmosphere or near animal matter in a state of decay, and had thus become impregnated with the germs of protoplasmic life? What gives still further interest to these experiments is, that having operated during the severe weather of last winter, when little or no life existed in the atmosphere, I was able to impregnate the fluids with germs without introducing developed life.

The quantity of life produced in the above-recited experiments being comparatively small, I was led to infer that this might be due to the influence of the atmosphere of hydrogen employed to displace the air in the apparatus used for obtaining the water. I therefore, on the 2nd of March, prepared a solution of albumen similar to that before employed, but expelled the air out of the apparatus by pure oxygen; and as the contents of the flask B were free from life on the 8th of March, a series of small tubes were filled and exposed for twenty-six hours to the atmosphere near putrid matter, and then sealed. Several of these tubes were opened on the 11th, and immediately examined, when only a few cells were observed in each field. A second lot was opened on the 14th, and they showed considerable increase of life, there being two or three vibrios under each field. A third quantity was opened on the 25th, when no increase had taken place. This latter result tends to show that, although oxygen appears to favour the development of germs, still it does not appear to favour their reproduction.

As the weather had become much warmer, and a marked increase of life in the atmosphere had taken place, some of the same albumen solution as had been employed in the above experiments was left exposed in similar tubes to its influence, when a large quantity of life was rapidly developed and continued to increase. This result appears to show that the increase of life is not due to reproduction merely, but to the introduction of fresh germs; for, excepting this fresh supply, there appears to be no reason why life should increase more rapidly in the open than in the closed tubes.

In concluding this paper I have great pleasure in recognizing the able and persevering attention with which my assistant, Mr. William Thompson, has carried out these experiments.

* During the intense cold of December and January last I found it took an exposure to the atmosphere of two days at a temperature of 12° C. before life appeared in solution of white of egg in the pure distilled water, whilst as the weather got warmer the time required became less.

GLYCERIZED COTTON FOR DRESSING WOUNDS.

Professor Gubler, at a recent meeting of the Académie de Médecine, exhibited some specimens of wadding prepared by saturating it with a certain quantity of glycerine, which he had found to render it permeable to all medicinal liquids, without causing it to lose any of its suppleness and lightness. He suggested that in this state it might prove a useful substitute for charpie, in the event of a scarcity of that article. Dr. Delaborde has already employed it with advantage. In order to prepare this dressing, it is only necessary to pour a small quantity of glycerine over the square sheet of wadding, and afterwards express it as strongly as possible.—*Journal de Pharmacie et de Chimie.*

TABLE OF REACTIONS OF DIGITALINE AND OTHER SUBSTANCES SIMILAR IN PHYSIOLOGICAL ACTION.

(*From Dragendorff's 'Untersuchungen aus dem Pharmazeutischen in Dorpat.'*)

Name.	Physiological Action.	Sulphuric Acid.	Sulphuric Acid, slightly diluted.	Sulphuric Acid and Bromine.	Proehde's reagent.	Muriatic Acid.	General Remarks.
Digitaline.	Irregularity and retardation of action of the heart; cessation mostly in the systole; no paralysis of extremities.	Green solution.	Green.	Reddish-brown; on addition of water, green.	Dark orange, red and at last greenish-brown.	Yellowish-green, then emerald green.	
Digitaleine.	Same as above.	Reddish solution.	Pale green.	Fine purple-red; on addition of water, green.	Same as above.	Greenish-brown.	
Convaleamarine.	Same as above.	Yellow solution, brownish-red, at last turning violet, starting from side of test tube.	Violet coloration at once on adding a little water to the test with sulphuric acid.	Does not turn red, or, if so, colour owing to bromine water.	Same as with sulphuric acid.	Red solution on warming.	
Helleboreine.	Cessation in the diastole, muscular action and reflex undiminished.	Almost instantly splendid red solution, gradually turning violet.	Remains red if not too much water added.	Colour produced by sulphuric acid becomes turbid by bromine.	Same as with sulphuric acid, but coloration soon fades.	Colourless solution.	
Active principle of Saponaria and Quillaya.	Cessation in the diastole, paralysis of extremities, reflex weak or not perceptible.	Brown solution, turning bluish-violet or red on exposure to air from side of test tube.	Once red or violet remains so, even with two volumes of water.	Turbid or reddish.	Same as sulphuric acid, but after a time violet not so pure.		
Senegine.	Action weaker than above, but similar.	Yellow, afterwards reddish-red, then violet and red.	Colour produced by sulphuric acid remains so, even with one volume of water.	Remains brown.	Brown, slightly violet.		
Smilacine.	Action still more gentle.	Solution brown, afterwards red.	Brown solution with sulphuric acid becomes red on adding water.	Remains brown.	Same as with sulphuric acid.	....	Insoluble in benzine.
Veratrine.	Subcutaneous injection produces tetanus.	Yellow, then brown, lastly permanently red.	A little water produced this red colour more rapidly.	Bromine rapidly produces red colour, as with above.	Red colour less pure than with sulphuric acid.	Turns red on being boiled.	Alkaline reaction.
Delphinine.	Cessation of action of heart in the diastole.	Reddish-brown.	Four volumes of water dirty light red.	Same as digitaline, but fading more rapidly.	Reddish-brown, then brown.	Colourless.	Alkaline reaction.
Antiarine.	Cessation of action of heart and of respiration.	Colourless.	Colourless.	?	?	Colourless.	
Cascarilline?	No action.	Reddish-brown.	....	Reddish-brown solution; sometimes shows violet bands.	Brown.	Colourless.	
Active principle of Dulcamara.	No action.	Yellow, then reddish.	....	....	Yellow, then reddish.	....	Alkaline reaction.
Active principle of Jalap.	No action.	Brown, then violet or red.	....	....	Same as sulphuric acid.		
Active principle of Pimento.	No action.	Brown, then bright red.	....	....	Same as sulphuric acid, but change of colour more quickly.		

DISINFECTION.*

No. I.

A disinfectant is, in the broadest acceptation of the term, anything which counteracts infectious, contagious or effete matter. How a few disinfectants produce their effects is perfectly understood, and presents no kind of mystery; how other disinfectants work is matter of dispute, and regarding the action of a good number of them we have as yet hardly arrived at the stage of controversy.

The material whose effects are to be opposed by disinfectants is held by some authorities to be animal or vegetable germs, and by others to be subtle organic poisons of surpassing power; and possibly enough may be of all these kinds, but must at any rate consist of complex organic matter. In common with all organic matter, the matter of contagion may be destroyed, and therefore rendered inoperative, by exposure to a red heat, in presence of excess of oxygen. Fire, therefore, is a disinfectant whose action is intelligible, and whose absolute efficacy is undoubted. It is one of the most ancient disinfectants, and is, for many purposes, unrivalled, and likely to remain so.

The action of destructive chemical agents, such as hot concentrated sulphuric, nitric or chromic acid, is, in like manner, quite intelligible. Disinfection by such means is perfectly certain, but it would be costly, and there are not many instances where such agents can be employed, and where fire might not be resorted to with greater economy.

We have instanced disinfectants which are effective and impracticable, in order to throw light on those which are practicable and not effective or much in vogue at the present time. Chlorine, which, in the form of bleaching powder, is much employed as a popular disinfectant, will necessarily destroy contagious matter, as it does all organic matter if suitable precautions be taken to ensure the conditions under which it can act thoroughly. But to use chlorine under these conditions is no more practicable than to use boiling concentrated nitric acid, and the manner in which chlorine is actually used, and that which alone is practicable, is not effective.

Suppose, instead of burning the clothes of the plague-stricken patient, we were to reduce them to pulp, bleach the pulp, and make paper of it, should we get plague paper from the plague rags? We cannot guarantee that we should not, but if we pushed the action of the chlorine further, destroying the pulp so that it could not make paper, and until complete chemical disintegration, then we could guarantee that it would not be infectious. If, then, there be doubt whether the paper made from some descriptions of infected rags be infectious, what shall we say of the chances of the decomposition of infectious matter by the popular expedient of just sprinkling clothes with a little bleaching liquor? Fumigations of sick-rooms with chlorine gas are not likely to be effective, for long before the proportion of chlorine in the atmosphere could reach the point at which we could hope for any attack of infectious matter existing in the atmosphere (and certainly very long before we could guarantee any attack of the infectious matter), the smell of chlorine would have become unendurable. In fine, the actual practical employment of chlorine, as a disinfectant, does not rest on a sound chemical basis, and we are not warranted in assuming that any great good is done by it.

Leaving disinfectants which aim at the chemical disintegration of infectious matter, we pass on to others, the *modus operandi* of which is in dispute. Corrosive sublimate, carbolic acid and sulphurous acid,—do they poison the germs, or are they chemically incompatible in relation to the organic poisons? We shall not discuss this question on the present occasion, but it is a fact, ascertained by experience, that these substances, in common with very many others, have some power of suspending the action of infectious matters, Of late years it has been the fashion to single out carbolic acid as pre-eminently serviceable. But Dr. Sansom, who is one of the warmest advocates of the use of carbolic acid, has shown that if we measure its activity by its power of arresting fermentation it is far behind corrosive sublimate; and if by its destructive action on low forms of animal life—on spermatozoa, infusoria and entomostraca, it comes behind corrosive sublimate and most of the commonest acids. In short, there is no reason why carbolic acid should be so singled out, whilst its being notoriously poisonous makes it no fitter for general and popular use than corrosive sublimate.

As we have said, the list of disinfectants is very wide. It includes such substances as common salt, which, according to Dr. Sansom's table, has about one-twentieth the disinfective power of carbolic acid. It appears to us that, whilst possibly all may have their uses in skilled hands, for household and popular use, we must avoid corrosive chemicals, poisonous substances, and bad-smelling things, and select agents which, having none of these properties, can be employed thoroughly and unsparingly. The property of deodorizing is also one which will be valued in a popular disinfectant, and since most of the common bad smells are stinking alkaloids, a great variety of substances, including all the acids, will possess this property.

We shall return to the subject and discuss the uses of the several disinfectants.

THE INDIA-RUBBER OF COMMERCE, WITH REMARKS ON ITS PREPARATION.

BY JAMES COLLINS.

American Varieties.—The Brazils supply the finest rubber known to commerce as "Pará." It is obtained from different species of Seringa—*Siphonia* [*Hevea*]. The trees are very common in the Amazon districts, and Pará is the port of shipment,—hence the name. *Siphonia elastica* (or *Hevea Guayanensis*) has long been known. The rubber is obtained from the trees in the following manner:—A deep transverse cut is made through the bark near the base, then one perpendicular to near the beginning of the branches, and from this other cuts in a diagonal direction are made.

The juice flows out, of the consistency and colour of thick cream, into a basin of clay placed at the base to receive it. This cream contains about 30 per cent. of pure rubber. Clay moulds are then dipped into the crude milk, to which the rubber adheres in a thin film, and is dried over a fire made of the oily fruits of the Urucuri palm. Sulphur is also used to expedite the operation, so that vulcanization is not so new as patents would lead us to believe. The same process of dipping and drying is repeated till a sufficient thickness is attained and the moulds removed. These successive coatings give the rubber the laminated appearance which is so very noticeable in most descriptions of Brazilian rubber. In the case of Ceará rubber, the trees are incised, and the rubber allowed to dry on them, and afterwards picked off, giving the rubber a stringy character. Pará rubber is known under four forms,—1, flat pouches, or biscuit; 2, the well-known bottles: 3, negro head; and 4, "scrap." Of these, the first is the best—the last two consisting of refuse.

British and French Guiana yield but little rubber, although capable of yielding much larger quantities. It is probably obtained from the same tree as the Pará kind, but is not equal to it in quality.

Venezuela, New Granada, Ecuador, Peru, Costa Rica, Nicaragua, Salvador, Honduras, Guatemala and Mexico, all yield india-rubber in greater or less quantities, and all too obtained, there is reason to believe, from one and the same tree. This tree is called by the natives *Ule* or *Ulequahuitl*, known to botanists as *Castilloa elastica*. The varieties of this rubber known in commerce are, "West India," "Carthagena," "Nicaragua," "Honduras," "Guayaquil," "Guatemala." These varieties are here arranged according to their relative value. The rubber is collected by companies of men called *Uleros*, in the following manner:—Having selected trees, long, perpendicular incisions are made down the trunk, and on either side of it short, diagonal ones, and an iron spout is driven in at the basal end of the perpendicular channel, down which the crude milk runs into a pan holding about five gallons placed to receive it. A tree of 4 feet in diameter and about 20 to 30 feet to the first branches, yields about 20 gallons, containing about 40 lb. of pure rubber in solution. At the end of the day this milk is collected and brought to the common workshop, where it is passed through sieves to free it from pieces of bark and other impurities. In Nicaragua, the juice of the *Achuca* plant (*Ipomœa Bona-nox*) is added in the proportion of a pint to a gallon of milk. On mixing these the rubber quickly coagulates. Where this plant is not obtainable, salt water is substituted. To every gallon of milk two gallons of salt water are added. These are placed in a barrel, and allowed to stand for twelve hours. After the rubber has coagulated it is taken out, the water pressed out by the hand, and then subjected to the heaviest available pressure, either by using heavy stones, hydraulic presses or rollers. It is then hung up wet, exposed freely to the air, and loses about two-thirds of its weight. We next turn our attention to Asiatic kinds of rubber.

Malayan Archipelago.—Our chief sources of supply from this portion of the globe are Singapore, Borneo and Java. Singapore is but an *entrepôt* for the produce of neighbouring countries, native sources being long ago exhausted. Singapore (so-called) and Java rubber are obtained from fig-trees. *Ficus elastica* is the chief plant which yields it. This plant is too well known to need any description; its dark green, glossy leaves are seen everywhere, it being a great favourite as a window and greenhouse plant in this country. To obtain the india-rubber the trees are incised, and the rubber allowed to trickle down the trunk. When dry, it is collected in the form of strings, and rolled into balls or pressed into large slabs. "Borneo" rubber is collected from a trailing, vine-like plant, the *Urceola elastica* of botanists, of which there are three varieties recognized by the natives, viz. *Serapit*, *Petabo* and *Menungan*. The juice is treated with salt water, which speedily brings about the coagulation of the rubber, the outside of which being acted upon first, encloses small quantities of salt water in numerous little cells.

India.—Assam rubber is the only kind of rubber which India supplies to the English market. It also is obtained from the *Ficus elastica*, and is collected in the same manner as that of Java and Singapore.

Madagascar.—This variety, which is beginning to figure in our commerce, is obtained from a trailing, vine-like plant, called by the natives *Vaughinia* (*Vahea* sp. of botanists), by incision, and coagulation brought about by treatment with salt water or artificial heat. In the Johanna and Mohilla islands the same plant occurs.

Eastern Africa.—In the Zambesi, Zanzibar and Mozambique districts rubber plants have been found, but, with the exception of the latter, one parcel of which has been sent to England, no quantity of rubber has as yet appeared in commerce.

Southern Africa.—Efforts have been made to utilize the sap of various species of *Euphorbia*, but with no present result.

Western Africa is our chief source of commercial rubber in Africa. From the west coast rubber is obtained from climbing plants, which have jasmine-scented flowers, and stems of from 4 feet to 6 feet in diameter. They are found to be a species of *Landolphia*. The natives cut the stems, and allow the rubber to trickle down their arms, and remove it in the various forms of balls, tongues, etc.

By a careful examination of the whole subject, I have found that there are six modes of preparing rubber. These we may arrange in two groups, thus:—

Group 1.—Coagulation brought about by heat. Examples—(1) Artificial heat, ex. Brazilian, etc.; (2) Natural heat, ex. Ceará and Ficus group.

Group 2.—Coagulation brought about by the addition of various substances; (3) Alum, ex. Brazilian; (4) Certain plants, ex. Nicaragua; (5) Fresh water, ex. Nicaragua and Madagascar; (6) Salt water, ex. Borneo, Madagascar.

Of these methods, that pursued at Pará, namely, by the careful application of artificial heat, especially if aided by the use of sulphur, is undoubtedly the best, and produces the finest rubber. The preparation by natural heat has the disadvantage of requiring a second visit to the tree, whereas, as a rule, the scene of operation has to be constantly changed. Of the second group, viz. a *wet process*, in contradistinction to the first group, a *dry process*, the addition of a solution of alum is in great favour in Brazil, inasmuch as it enables the operation to be conducted in the collectors' own houses, a desideratum of great value on the score of health alone as the exhalations from the decaying vegetable matter on the river banks, which, on account of the inundations, are nothing but mud, are fruitful sources of deadly fevers. The wet process, however, has one very serious disadvantage. The rubber thus treated is never free, unless very old, from water, and dryness is next to purity in constituting value in rubber. In the Guatemala and Guayaquil rubber, a dirty, tarry, resinous matter exudes, which greatly detracts from the value, it being very difficult to get rid of. In the Borneo kind, when a piece is cut through, the water is seen in little cells, and has a very saline taste.

Purity and freedom from false packing is, as already hinted, the *first* and main point to be attended to in order to produce a good, marketable rubber. The adulteration may arise in various ways:—1st. By careless collection, in allowing bark, clay, or other materials, to fall into the milk. It is an excellent plan to pass the milk through sieves in order to separate these impurities. It is important that the *form* in which rubber is made up should not be lost sight of. Large masses *never* will fetch so high a price as small pieces, as in the latter case the facility of adulteration or false packing is reduced to a minimum. By far the best plan is to prepare the rubber in thin, separate sheets, or cakes, and if a mould is used to use wooden ones, a large-sized battledore, such as is used by children, being an excellent mould in every respect. Secondly, care should be taken not to mix the milk of another tree with that of india-rubber. Of course this caution should not deter any one from searching for such milky juices as are likely to be of use to send as samples home. Bad preparation and intentional fraud should be guarded against.

The *quality* and quantity of rubber is much influenced by the time of year at which it is collected, and these facts should be noted. The trees require, after each tapping, a period of rest of about two years. Binding the trees and overtapping injure greatly, and should be strenuously guarded against, but many interesting facts may be noted in connection with this subject, and would prove highly valuable. Total destruction of the tree is barbarous and intolerable, and should be put a stop to by all possible means. Efforts and experiments should be made in the direction of cultivation, and as to how the trees are best propagated, and how long they are before they come to maturity. As there are some, doubtless, who, from residence and other favourable circumstances, would be willing to collect a series of specimens which would enable a definite opinion to be formed of the value of the rubber, and allow some useful hints to be offered, suggestions are therefore made here only as to the *kind* of specimens, leaving it to the collector to add to the list as opportunity offers, and usefulness would suggest.

1. Samples of crude juice, without any preparation whatever, care being taken to place the same immediately in *air-tight* vessels to guard against any spontaneous change taking place. If two such specimens can be sent, to one might be added a small quantity of ammonia, as this checks coagulation. Care should be taken to exclude light.

2. Samples of rubber, prepared in as many different ways as possible, such as those enumerated, care being taken to note the time occupied. and which gives the best result in quality and quantity, a *uniform* quantity being used in each trial.

3. Samples of the whey-like substance which separates from the india-rubber during its coagulation.

4. Samples of prepared rubber in the form or forms proposed to export it in, care being taken that it is as *clean* and *dry* as possible.

5. Note the average yield of each kind of tree, and the relative yield by simple tapping; 2, tapping, aided by binding; and 3, total destruction, the best season to conduct the operation, the effect of tapping on the vitality of the trees, the period of rest required. Of course neither binding nor total destruction should be had recourse to in practice.

Specimens, illustrating such notices, would be exceedingly useful.

Our knowledge of the botanical origin of many of the milky juices needs much enlightenment; and it is highly desirable that complete series of botanical specimens should be obtained. The following is a list of specimens which should be collected in order to be as complete as possible.

1. Dried specimens of a branch, having the leaves, flowers and fruit attached. These may easily be dried between sheets of any porous paper, care being taken to change the paper a few times at first to ensure perfect dryness, and to guard against mouldiness. The specimens should be as characteristic of the tree as possible—leaves on different parts of a tree in some instances vary considerably.

2. Specimens of leaves, flowers and fruits attached, preserved in a jar or bottle, in some spirit, such as brandy, spirits of wine, or acetic acid, and tightly corked and secured to prevent leakage.

3. Specimens of the wood and bark and india-rubber gathered from the *same identical tree.*

4. Where there is more than one kind or variety of tree yielding the same substance, complete specimens of each kind or variety should be sent.

I shall be happy to receive and report on any such series of specimens, and will gladly acknowledge them in any future papers on the subject I may publish.—*S. W. Silver and Co.'s 'Colonial News,' London.*

REARING OF THE COCHINEAL INSECT IN THE CANARY ISLANDS.

In the Canary Islands the rearing of the cochineal insect, for the purpose of export, is carried on to a considerable extent, and forms the bulk of the contribution from these islands towards supplying the necessities of commerce. According to the official returns for 1869 the quantity of cochineal exported thence during that year amounted to 6,316,000 lb., the estimated value being £842,921. Of this quantity, no less than 4,232,600 lb., valued at £554,092, was exported to England. Some idea of the development of this industry may be formed from the fact that the exports, which in 1865 were under 2,400,000 lb., had increased, in 1867, to over 5,000,000 lb., and, in 1869, to 6,316,000 lb., more than half of which was exported from the island Grand Canary. In fact, cochineal rearing is so profitable and is augmenting so fast, that it attracts all the available capital in the island. A consequence of this is, that the necessaries of life, which were formerly produced in these islands in great abundance, are no longer to be obtained in sufficient quantity to meet the wants of the population, except at a greatly increased price. Steps have therefore been taken by the provincial authorities to obtain from the Spanish Government permission to import from Morocco live-stock and other articles of consumption.

A very interesting report on the method of rearing the cochineal insect in the Canary Islands has been furnished by Mr. Consul Grattan, from which we abstract the following particulars:—

The cochineal insect is a species of coccus about the size of a pea; it has a silvery grey appearance, the body being reddish-black and covered with fine white dust. When first brought forth the insect moves about freely, but as it grows it fixes itself to the leaf from which it derives its nourishment. There are several varieties of the prickly pear plant on which the cochineal feeds, but that most generally cultivated for the purpose of breeding is the common hardy *Cactus opuntii.* In a wild state this plant brings forth abundance of fruit, and it formerly supplied one of the principal articles of food to the inhabitants of the Canary Islands. The fruit is found to debilitate the plant when used for the purpose of rearing cochineal, it is therefore carefully removed as fast as it buds. The cactus plant is so hardy as to grow luxuriantly on rocky spots, where there appears to be scarcely soil enough to fill the crevices; but in this state it cannot serve for the rearing of cochineal for more than one or two seasons. In rich soil, and with abundance of manure and water, the same plants will continue to yield excellent crops for from ten to twelve years.

The best soil is that which is found in volcanic countries, where pumice stone and black scoria abound. Where no artificial irrigation can be obtained, a layer of black scoria, called here "picou," covering the ground to the depth of several inches, is found greatly to improve the plant, by retaining the moisture of the soil and protecting it from the heat of the sun, and also by preventing the growth of weeds, thereby keeping the land constantly clean. In those parts of the Canary Islands where the soil has been overrun by lava, and on which the vegetable growth is confined to lichens, mosses and here and there small ferns or weeds, the preparation of the land for the cultivation of the cactus is a long and costly process, the expense of the process varying according to the hardness of the rock, to the abundance of subsoil, and to many other circumstances. Where there is abundance of earth on the surface, and the preparation consists only in levelling the ground for the facility of planting and of irrigation, the cost is much less, but a thorough upturning and airing of the soil is found to be essential to the successful cultivation of the cactus. The cactus plant is propagated by the leaves, which are broken off sharply one at the time, and exposed to the heat of the sun for about three weeks before they are planted; if the leaf is put into the ground fresh and moist as at first gathered, it is almost sure to rot; but when allowed to dry in the sun until slightly bent, it will strike root and bud with facility. During the summer months, leaves so dried will be found to bud in ten days or a fortnight with great profusion, as many as eight or ten new leaves bursting forth at the same time. They are planted in furrows at about a yard apart, either edgeways, as close as possible, or about four inches apart if placed across the furrows. This is done in May or June; in four or five months the new leaves will have grown to their full size, and the plants will then be ready for transplanting. Here the furrows are at least two yards apart, in order to admit of a free passage to the labourers amongst the plants after they have grown to their full size; and each plant is placed half a yard from that on either side of it, to allow sufficient space for its full development, which takes place in February or March. Each leaf buds with about from five to fifteen shoots, according to the nature of the soil and to the quantity of manure and water supplied to it. In handling these plants great care is taken to avoid bruising the main trunk; if by accident the hoe should be struck against it, the only way of saving the plant is to cut out the injured piece, the fresh cut will then probably dry and the plant be none the worse; a bruise, on the contrary, gradually causes the whole trunk to become soft and putrid. A considerable quantity of ordinary manure or of guano is required to bring the plants to perfection.

Having by these means obtained by the end of May or June well-grown cactus plants, consisting of four or five branches, springing from each trunk with a good supply of rich dark-green leaves; when the fleshy spines and prickles have fallen from them, the plantation is ready to receive the insect. The state of the weather during the growth of the "madres," and the temperature at the time of spawning, has a great effect upon the amount of seedlings produced. The mothers are put into small bags made of a material called "renque" (a sort of gauze), about eight or nine inches long, and shaped somewhat like a sausage, in each of which is put about a table-spoonful of "madre," it is then hung over a leaf in the cochineal plantation. The young, as they are born, walk out of the bag on to the cactus, and spread over the surface of the leaf. The quantity of insects spawned in a given time will vary according to the heat of the weather and the age of the "madres": with fresh "madres," and in warm weather, a couple of hours will be enough to cover the leaf sufficiently; with old "madres," and in cool weather, the bags may be left on the leaves as long as thirty hours, or even two days; the leaf, on removing the bags, should be moderately and evenly covered with insects. If the insect is allowed to spawn too freely on each leaf the crop will be damaged in quality, and if the bags are removed too soon the crops will be deficient in quantity. The obtaining of a fair average number of insects on each leaf is therefore one of the most important points to be looked to in the cultivation of cochineal, and one which requires experience and constant supervision on the part of the grower.

Another way of conveying the spawn to the leaves is the following: the "madres" are spread on shallow trays about 4 or 5 inches long and 2½ inches wide; some entirely made of wood, others a framework of wood with a bottom of thin canvas, nailed on so as to prevent the escape of the young. The "madres" being laid thinly over the surface, so as to lie closely side by side, but not one over the other; pieces of rag, about half a yard long by five inches wide, are then spread over the whole surface of the tray; in a short time these become covered on the under side with the young insects, and being removed are conveyed to the plantation in baskets; they are one by one pinned on to the leaves, on which the young insects soon fix themselves; fresh rags are then laid over the "madres" to be again covered with the young. It is found that white rags are best, black and dark colours are *disliked* by the insect. The same difficulty as to the number of insects conveyed to each leaf, exists in this method of planting as well as in the former, with a new element of difficulty, viz., that the production of the young varies with the amount of light admitted into the room. To ensure the greatest quantity of spawn in the shortest time, it is therefore necessary to have a skylight to the room, and it is not improbable that the preference for white rags is owing to their admitting more light to the insect. After pinning the rags to the leaves they are left for a longer or shorter time, according to the state of the weather: in fine and warm weather twenty-four hours suffice, but when the weather is cold and damp they are not removed for three, four, or more days. In the winter season the rags used formerly to be left upon the plants until the time for gathering the crops, in order to protect the young insects from the inclemency of the weather, but experience has shown that this object is better obtained by other means. It may be as well to mention here, that for a winter crop the insects are allowed to spawn far more copiously on each leaf than in summer, as the cold, rain and winds of that season destroy a great many.

When the "madres" have exhausted their powers, which occurs sooner or later, according to the temperature to which they are exposed, and which is known by the young being born black instead of white, they are collected from the bags or trays in which they have been spawning, and put into an oven for drying. The young insect takes more or less time in coming to maturity, according to the weather. Those planted in June are often ready to be gathered in seventy days, or even earlier, whereas those planted in October and November are not ripe till late in February or early in March. Those planted in the latter season, which are intended exclusively to serve as "madres," are allowed to ripen thoroughly before they are gathered, and are not taken off the plant until there are some young to be seen crawling over the leaves. On the other hand, the cochineal planted in March or April for "madres" spawns with such astonishing rapidity in June or July, under the influence of the heat of those months, that, as soon as the first leaf in a plantation which has taken three or four days to cover with insects, is seen to have young upon it, the whole is gathered, for even those that require some hours before arriving at maturity will ripen in warm weather.

The cochineal planted in June and July being the great crop of the year, prepared principally for drying at once into silver cochineal, should be gathered before it commences to spawn. Thus during August and September the grower watches for the first symptoms of spawning, and as soon as they appear, not a moment is lost in proceeding to immediate gathering, for the weather being then quite as warm and bright as in June, the same rapidity in ripening is observable, and the loss of weight is serious if the spawning is allowed to proceed for even a few hours. The proper manner of gathering varies according to the object to which the plants are devoted; but, as a general rule, the leaves on which the bags are placed are sharply cut off with a knife, close to the branches, and the cochineal swept off them into closely woven broad baskets. After the leaves are all cut off and swept they are dropped into the ridges, *where they are left;* another set of gatherers carefully scrape off the insects which have passed into the branches or trunk of the plant; to leave even one or two insects on these branches is fatal to the health of the plant, as they spawn, most probably in hidden spots, and shortly afterwards the strength of the branches, which is required to produce new leaves for the ensuing year, is absorbed by the surreptitious growth of insects, and this is fatal to the future crop. To prevent any young insects remaining on the plants after gathering, the branches are swept several times every two or three days. By this means such as may escape the first or second sweeping, having both grown and changed their position, will be removed on the third or fourth application of the broom. A small insect grows in a few weeks into a "madre," and will propagate several hundreds of young which will eventually much weaken the plant. The leaves cut off at the gathering of the crop, are now chopped up into small pieces and dug into the ground to lighten it, and by their fermentation they warm the roots of the plant, and act as excellent manure; guano is also applied freely. It is found that as much as 15 quintals of guano per 1½ acres can be applied with benefit to the cochineal; a grower at Grand Canary used as much as 25 quintals on one occasion, and was rewarded by a return of from 11 to 12 quintals of cochineal, or nearly double the average crop.

To prevent so much guano injuring the plants, artificial watering is freely resorted to if necessary; a good soaking being given to the ground every three weeks. The cactus cannot bear much water when not strengthened with manure, neither can it bear much manure unless it is copiously watered.

When a plantation is reserved for the production of a winter crop, the leaves are covered with cochineal in the months of October or November; the young cochineal planted at this season ripens, and is ready for gathering at the latter end of February or of March. Another plantation of cacti is reserved for receiving the seed at this season; but as the plants cannot be forced to bud during the winter, the seed must be planted in March upon last year's leaves, which have the disadvantage of being tough for the insect, and this renders a winter crop more precarious than one obtained in summer. However, the sale of "madres" in June brings a quicker return than the dry crop of August or September. The wind and rain during the winter months frequently destroy half the crops, and in summer a hot south wind ("levante") will often kill many of the insects. In order to prevent the losses thus occasioned, light covering of cotton gauze is spread over the whole plantation upon stakes and wires, at a height of about 7 feet. Mats have been used for the purpose, amd also calico, but these materials are found to injure the insects during the winter by keeping off the sunshine, and in summer by preventing the free circulation of air. The baskets are emptied as soon as possible,—the insects that lie at the bottom being injured by the weight,—and the cochineal spread out on trays, or even on a sheet on the ground, not deeper than from two to three inches, otherwise the grain will assume a reddish tinge, which considerably diminishes its value. The cochineal gathered during the day is treated in this way, and towards evening is put into an oven heated to about 150° F.; there it is left for four or five hours, the temperature being carefully kept up; afterwards the oven is allowed to cool gradually until the morning, when the insects are still moist. Exposure to the sun for a few days in summer will complete the drying, and it is found that there is less loss of weight when the cochineal is dried in this manner than would occur if subjected to greater heat, or if left a longer time in the oven in order to dry it at once; even in winter many growers prefer to let their cochineal dry slowly in the air rather than by the heat of the oven, the loss of time being of less importance than the loss of weight. Some growers do not use the oven; a tablespoonful of wood ashes is spread over a pound or two of cochineal, it kills it in a couple of hours; the dust and ashes are then shaken off from the grain in a sieve, and the cochineal is dried in the sun. Others prepare the cochineal by putting it into sacks in moderate quantities; two men grasp the sacks at each end, and shake the grain briskly backwards and forwards; this process gives the cochineal a brilliant polish, and though less weight is finally obtained from a given quantity of green cochineal, the price it commands in the London market compensates for the loss of weight. But the best processes for preparing this polished cochineal are known only to a few, who keep the secret jealously; the oven is, therefore, still almost universally used for drying.

After the grain is thoroughly dried, it is well sifted in order to free it from a white powder which to the last clings to it; numbers of prickles which have fallen from the leaves have also to be removed. Excellent machines have been invented for this purpose both in England and America. The cochineal being thus dried and cleaned, it is packed for exportation into bags containing about 150 lbs. each, which are carefully sewn up. This is done by the trader who buys it of the cultivator, the latter rarely exporting the grain on his own account. The results obtained by different growers of cochineal vary so much, in consequence of the peculiar circumstances to which the crops are exposed in different localities, that it is impossible to fix upon the actual value of an average yield per acre; but it is universally admitted by the land owners in the Canary Islands, that no other branch of agriculture is as remunerative. The average temperature in the southern part of the Canary Islands is about 80° to 85° F., and it rarely falls at night below 56° or 60°. At Laguna and at Orotora, and other places in Teneriffe, where cochineal is cultivated at a height of nearly 2000 feet above the level of the sea, the climate is temperate,—the thermometer rising to 72° or 78° in the summer, and falling at times during winter nights to 45°. In all these places the cactus thrives, and cochineal can consequently be reared successfully.

The average price at which the "madres" can be obtained varies much at different times, falling as low as 9*d.*, and frequently rising to 2*s.* 6*d.* and even 3*s.* per pound.

The management of the insect gives employment to a large number of women; it may almost exclusively be conducted by them. The larger proprietors employ most of their hands during the whole year, so as to command a full number when the labour of the season comes on. The wages of the women in the valley of Orotora is 6*d.* per day, or 3*s.* 6*d.* per week for the best workers. Day labourers receive at the rate of 6*s.* 3*d.* per week for digging and planting, etc. etc. The successful culture of the cochineal requires experience and patient attention on the part of the grower; he will receive his reward by obtaining a return of from 25 to 30 per cent. upon the capital employed.

COMPOSITION OF CUBEBS.

BY E. A. SCHMIDT.

The analysis of fresh cubebs gave the following result:—

	Per cent.	
Water	4·75	
Essential oil	14·22	
Brown colouring matter	6·94	=23·84 soluble in water.
Gum	8·19	
Starch	1·78	
Albumen	2·71	
Extractive matter and salts	4·22	
Oxalate of lime	0·40	
Cubebine	2·48	
Acid resin (cubebic acid)	0·96	
Indifferent resin	2·56	
Green fatty oil	1·18	
Greenish-yellow soft fat	0·51	
Vegetal skeleton	43·07	
Loss	6·03	
	100·00	

The essential oil is colourless or pale green, tasting and smelling intensely of cubebs; it consists of two oils, the one being lighter, of sp. gr. 0·915, boiling-point 220° C., the other being less than one-half, has a sp. gr. of 0·937, and boiling-point 250° C. They both contain 88·26 C and 11·74 H, corresponding to $C_{30}H_{24}$.

It is neutral, soluble in 17 parts of absolute alcohol, it fulminates with iodine, is decomposed by sulphuric acid, and gives with hydrochloric acid vapour a solid and a liquid compound. The oil of fresh cubebs does not contain any stearoptene, like that made from old cubebs.

Cubebine forms fine white needles, by itself it is tasteless, but it imparts a bitter taste to an alcoholic solution; it is insoluble in cold, and slightly soluble in hot water, soluble in 30 parts of ether, and in 75 parts of alcohol; also in chloroform, bisulphide of carbon, acetic acid, and in fatty and essential oils; it melts at 125°–126° C., boils at 190° C., but does not volatilize. It is neutral; concentrated sulphuric acid colours it red, nitric acid brown.—*Archiv der Pharm.* cxli. 1.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 30, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE APPLICATION OF THE PHARMACY ACT.

Though we have lately heard much about pharmaceutical monopoly, and the limitation of the right to sell drugs has been spoken of as though it were a ground for reproach, cases are constantly being reported in the daily papers which show that the interests of the public would be more secure if that limitation were more rigidly enforced than it is. Only last week we reported the case of the grocer at Weeley selling laudanum in place of syrup of poppies; and this week we have another case, in which laudanum was given by mistake for tincture of rhubarb.

A provincial paper, in speaking of this case, asks who is the Local Secretary of the Pharmaceutical Society at the place where this occurred; and the writer goes on to say that he should take care not only of the interests of chemists and druggists, but should also see that grocers and others do not sell poisons; and we take the opportunity of mentioning the opinion thus expressed, because we have reason to believe it is one not uncommonly entertained.

A little reflection, however, will suffice to show that such an opinion involves a serious misconception of the duties a Local Secretary of the Society may be expected to perform. It would, in fact, convert those officers into a kind of special police, and, in many instances, might interfere seriously with their own business. In regard to this point it cannot be too strongly urged that under the Pharmacy Act 1868 any one has the power of proceeding against those who deal illegally in poisons, and it would seem that the persons who should do this are those who may be injured. We are constantly receiving letters from members of the trade complaining of the sale of drugs by grocers and other unqualified persons as a practice that is unfair and prejudicial to themselves, and we would recommend to all such a careful study of the Act and its provisions, for we feel sure they would thereby come to see how easily they could protect themselves by its aid.

While speaking of the Pharmacy Act, it may not be amiss to refer again to the very general ignorance prevailing as to the requirements of the Act in the sale of poisons. This is conspicuous with magistrates and coroners. In one of the inquest cases reported this week a druggist was "severely censured" by the coroner for selling laudanum without registering the sale, and told "it was a fortunate thing for him that the evidence went to prove the deceased had not died from taking laudanum, otherwise the verdict would have been a very unpleasant one as far as Mr. Field was concerned," because, as the Coroner affirmed, "it was contrary to law for any chemist to sell poison without registration." It is inexcusable that those whose business it is to administer the law should commit such flagrant errors, and thereby, perhaps, inflict unmerited injury on persons who are in no way open to blame, but who have, as in this case, acted strictly in accordance with the Act.

THE COMING SESSION.

Before the next number of the Journal appears, the holiday season that precedes and follows the meeting of the Pharmaceutical Conference will have come to an end, and the usual routine business of the Society will have been recommenced by the evening meeting, which takes place next Wednesday. On that occasion our readers are aware there will be another of those inaugural addresses which have been for the past three years not only a source of much gratification, but also, we are bold enough to say, a means of exercising a most potent beneficial influence on those who had the good fortune to hear them. This year the series of addresses delivered by Brady, Deane and Schacht will be worthily continued by a pharmaceutist who has always been a staunch supporter of the Society, and has done much to promote the interests of his craft in Scotland. Not only for these reasons, and on account of his mature experience, but also because he is a thorough representative of Scottish character, we urge upon every one who can manage it not to miss the opportunity of hearing John Mackay.

COD-LIVER OIL JELLY.

Preparations of cod-liver oil appear of late to have attracted an unenviable notoriety. If the "palatable" cod-liver oil lately introduced be not more pleasant than the discussion which took place in this Journal in reference to it, we fear that preparation would find little favour. And now a similar difficulty has arisen in reference to the cod-liver oil jelly, which many of our readers will remember was exhibited at the Liverpool Meeting of the Conference. We believe that both, or, at any rate, one of these preparations has enjoyed the advantages of that kind of semi-editorial advertisement by the medical journals which they have lately adopted in common with their comic contemporaries. Some time ago a pharmaceutical correspondent drew our attention to this fact, and raised some doubts as to appropriateness of the recommendations awarded to these specimens of "elegant pharmacy." A medical journal, the *Practitioner*, stated that the amount of cod-liver oil contained in this cod-liver oil jelly was not much more than half what it was represented to be. In a subsequent number of that journal, attention was called to a statement of facts respecting the circumstances connected with a former analysis of cod-liver oil jelly, and also to the results of a further analysis as follows:—

"Our analyst, after making the first examinations, privately communicated their general result to Dr. Attfield, who had certified that a sample of the jelly analysed by him contained 75 per cent. of oil, Mr. Agnew at the same time certifying that all samples supplied to the agents should contain the same proportion of oil. Dr. Attfield, having completely verified our analyst's statement as to the serious deficiency in oil exhibited by various samples actually sold by several respectable London agents of the maker, immediately communicated the fact to Mr. Agnew, and remonstrated with him. The latter gentleman, without waiting for the appearance of our condemnatory report, put forward the following somewhat misleading statement in the weekly medical journals (dated May 19, 1871):—'Dr. Attfield has drawn my attention to a deficiency in the percentage of oil in recent parcels of my "cod-liver oil jelly:" in justice to the Professor, I beg to say that the deficiency has arisen through a miscalculation on my part, and that the error has been corrected.*

"It will be observed (1) that there is no mention of the fact that the error was originally discovered by an outsider (ourselves); (2) that the mistake is spoken of only as occurring in 'recent parcels,' whereas our analyst had detected the same deficiency in parcels of various dates, and also in the small samples of the jelly which were originally sent round to members of the profession; (3) that Mr. Agnew had himself published a formula (sent round with the small specimen samples), according to which the proportion of oil that should have been present was 83 volumes per cent., thus making the deficiency detected by us still more serious. We are thus reduced to the following awkward dilemma: either Mr. Agnew supplied a sample of the jelly to Dr. Attfield, for analysis, which did not at all represent the jelly actually in the market, or the latter gentleman made a mistake in his original analysis of from 15 to 20 per cent. Be that as it may, it is quite evident from the above detailed facts that such general certificates as those which were published by the maker of the jelly are absolutely valueless as a protection to the public, and that analytical chemists would do well altogether to refuse to give such testimonials.

"In consequence of the above declaration of the maker, we have thought it our duty to analyse samples of cod-liver oil furnished to the London agents, from the factory, several weeks after the date of that document. We regret to say that we still find a deficiency of 15 to 16 per cent., as the analytical details given below will sufficiently show. We leave the profession, the manufacturers of drugs, and the analytical chemists of this country to their own reflections and conclusions on the matter. We make no comment whatever on the motives of any persons concerned; but we must distinctly point out that but for the interference of the *Practitioner* a very serious and misleading manufacturing error might have been continued for an indefinite period."

* We think it only just to ourselves to state that the paragraph referred to was sent to us, and that we declined to publish it otherwise than as an advertisement.—Ed. Pharm. Journ.

To these remarks were appended the following report of the results of analyses of two samples of the preparation purchased of wholesale dealers in London:—

Number.	Cod-liver Oil. Per cent. by volume in volume.	Cod-liver Oil. Per cent. by weight in weight.	Sugar. Per cent. by weight.	Specific gravity.
I.	58·73	50·29	31·22	1081·4
II.	61·84	52·93	29·69	1080·8

"The jelly, if made according to declaration, should just about float in water; whereas the above readily sinks down in it, and floats only in a syrup containing ℥j of sugar to ℥iv of water."

The August number of the *Practitioner* contains a letter in which Mr. Agnew endeavours to defend himself by suggesting that the foregoing results were arrived at, not by analysis, but by calculation from the specific gravity. This is repudiated by the Editor of the *Practitioner*.

MORE ABOUT CONDURANGO.

There appears now to be but small probability that the great expectations once entertained that condurango would prove to be a remedy for cancer will be realized. The *British Medical Journal*, in a recent number, remarks:—

"All that we hear of the results of the trials given to the condurango bark furnished by our Government to the Middlesex and St. Bartholomew's hospitals, through the College of Physicians, confirms the fear that any hope which might have been entertained, of a confirmation of the statement of its utility as a remedy in cancer, must be entirely dismissed. Physiologically, it appears to be practically inert, and its therapeutic effects in the treatment of cancer to be *nil*. It furnishes a slightly bitter extract of feeble characters. A detailed therapeutical report will be made by Mr. Hulke, and a careful examination of its physiological action by Dr. Brunton, but this mainly in deference rather to the official sources from which the small supply has been furnished, and to set at rest the excitement caused by the somewhat scandalous claims which have been set up in its favour."

To judge by the following extract, the editor of the Chicago *Pharmacist*, too, has arrived at a somewhat similar conclusion, though the style of composition in which his opinion is announced slightly varies from that of the English journal, and the language is rather more racy of the soil than we are accustomed to meet with in our American contemporary:—

"It can hardly fail to cause the heart of the American pharmacist to bound for joy to know that Dr. Bliss, from blissful Washington, has announced the blissful intelligence that a cargo of cundurango has arrived in New York, which will be furnished to the profession at the highest possible prices. 'See, the conquering hero comes!' The very name cundurango has a high and mighty conquering sound—sweetly blended of high Spanish, Guinea Nigger, Fiji, and Whang Doodle. Dr. Bliss has taken steps to Helmboldize the drug at once. We will soon see it marching on across the Continent, side by side with the other heroic names which, by the magic of paint and cheap blacking, blazoned on every bridge, fence, and crag, from the Atlantic to the Pacific, have been stencilled upon the great American heart."

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Boiled Oils and Varnishes.

BY CHARLES W. VINCENT, ESQ.

(*Concluded from page 255.*)

The jacket and pan should be capable of standing a working pressure of 40 lb. per inch. The top of the pan is closed by a dome riveted to it, and forming part of it. This dome is provided with a man-hole, and in the centre is furnished with a stuffing-box, through which pass two shafts, one encircling the other, and each bearing a fan, which fans, by gearing outside the pan, are made to rotate in opposite directions, intersecting each other in so doing, and, as may be conceived, producing a most thorough admixture of any solid and fluid substances submitted to their dashing and cutting action. At one side of the top of the dome is a kind of cupola, from the top of which issues a three-inch pipe, which is carried down to the ash-pit below the boiler furnace. When at work, care is taken that every joint is tight, hence any vapours arising in the interior of the pan have no chance of escaping into the air till they have passed the burning coals. One of the greatest dangers and also disagreeable nuisances being thus obviated, oil-boiling can be, and is carried on without objection on the part of either the insurance companies or the public at large, even in the heart of densely-populated districts. I myself boiled oil and made varnish in Milford Lane, Strand, for three years, without increasing the insurance of the *Illustrated London News*, though I used steam from their boilers for the purpose.

At the lower part of the pan, the inch-pipe from a powerful air force-pump penetrates through the jacket to the interior of the pan.

The workman's first care is to see that all his taps and valves are in good, efficient order, and turned the right way, after which the mode of manipulation is the following:—

The linseed-oil is first shot into a large tank, holding one batch for boiling (about two tons is the usual quantity), and allowed to settle for four or five hours, according to the time taken for boiling the previous batch, matters being so arranged that as soon as one batch is pumped up into the pan another is shot into the tank, so that the oil may have as long a time for freeing itself from mechanical impurities as can be spared for that purpose. The waste steam from the pan passes through a coil of inch and a half iron pipe placed in this tank, so that the oil is also being warmed, this much facilitating the separation of particles of dust, mucilage, etc., and also saving time when the actual boiling commences. The time having arrived when the pan is ready, the oil has acquired a temperature of about 95° F. before it is pumped up (in the works I am describing the arrangement of pumps used took about seven minutes to elevate two tons of oil twenty feet), full pressure of steam is then turned on the pan, and the fan started. At first there is little or no disagreeable smell to be perceived. If the man-hole of the pan be open, an observer can watch the oil churning round with very little frothing, although the blades of the two fans, rotating in opposite directions, cause such a perfect commingling of the oil and the air that is in the upper part of the pan, that, looking in upon the whole fluid mass, it seems as if the bulk were greatly increased, as it goes on swelling and chafing, with a hollow rumbling noise, at the rough treatment it is receiving. A few minutes later, a faint, sickly odour is to be perceived, something like the smell of the raw oil, but intensified as to its woody constituents. The oil is now nearly hot enough for the air to be turned on. This may be done as soon as the steam reaches a pressure of 35 lbs. to the square inch on the pan. Directly this is done, the character and the appearance of the oil changes; the bulk appears to be still more increased, a foaming, seething, whirling vortex presents itself, the colour suddenly changes from the dark brown it previously exhibited to a mass of pale yellow bubbles, and the strong pungent odour universally accompanying the boiling of oil makes itself known and felt by the discharge from eyes and nose, if the curious observer does not take the hint that it is time the man-hole was closed, and the cauldron left to complete its witchery in darkness and solitude, if not in silence. But before it is left to itself, it may be well to observe that, before the air was turned on, a taper would burn in any part of the space above the oil where it was safe from being extinguished by splashes. After the air has been blown through the oil for a short time, if both the flue and air-pumps be stopped, so that a perfectly quiescent atmosphere remains above the oil, it is found to be perfectly incapable of supporting combustion. A few inches inside the man-hole, I have found that a brown paper torch, dipped in turpentine, has been immediately extinguished.

If a dark boiled-oil is desired, the driers should be put in as soon as the oil is thoroughly heated throughout its bulk, which is commonly about half an hour after the steam has an indicated pressure of 35 lbs. They are ground to a fine powder, mixed with oil, and are introduced through a funnel, with a stop-cock intervening between it and the pan, in a thin stream, so as to secure as perfect a distribution of them as possible throughout the oil. The quantity of driers used amounts only to about three quarters of a pound to each hundred-weight of oil, so that the necessity is obvious of great pains being taken to secure and maintain as complete a diffusion through the liquid as can be attained, and thus coincide with the theory of this method of oil-boiling, which requires that each particle of oil should be in contact or proximity to a particle of the drier used and oxygen at one and the same time.

Subsequent to the introduction of the driers, no attention is required to the process save to see that the air-pump and fan are kept constantly at work, and that the pressure of steam on the pan does not sink at all below 30 lbs., 35 lbs. being that which ought to be adhered to. The right quantity of air to be introduced for the oxidation of a given quantity of oil has not been ascertained. In practice, it is found that some oils require, and will consume a larger amount than others; the custom is to throw in as much as the oil will take without frothing up and priming into the condenser. The cooling effect of the air thus introduced is much less than might be supposed, in point of fact, the pressure to which it is subjected in overcoming the weight of the oil, lifting the heavy valves, and the friction tubes it passes through, considerably raises its temperature before it enters the pan; it is generally found to be raised some 20 to 30 degrees above the temperature it previously had by the time it reaches the oil. Indeed, the tubes through which it passes not unfrequently become hotter than the bare hand would be able to hold in a firm grip. In four hours' time the oil is generally fit for removing from the pan to a tank, where it can remain a sufficient time for the major part of the driers to settle out from it. When bright, it is then either pumped or run off into other tanks for warehousing, or may be allowed to remain where it is for the future use, if there are plenty of working tanks.

The mode of emptying the pan is by allowing the oil to rush out through a two-inch tap in the centre of the bottom of the pan into pipes which are connected by running-joints, and lead it in any desired direction. Sometimes, a little difficulty occurs in dropping the oil, through the orifice of the tap leading into the pan becoming stopped up by an accumulation of driers, or by pieces of the old skins of oil which may have fallen from the sides of the pan. This may be entirely obviated by causing the air to enter the pan through this tap, and putting the second tap beyond the air inlet as an outlet for the oil. The pressure of the air-pump will then suffice to remove any ordinary obstruction; but if a stoppage, nevertheless, should occur, nothing remains but to probe the tap with a long, thin rod from the top of the pan. Until this simple expedient of letting in the air through the oil outlet was adopted, this terrible nuisance was of almost daily occurrence.

The vapour which comes off from hot oil into which air has been blown is so intensely acrid and pungent that human nature seems to be incapable of ever getting used to it. For my own part, I would much prefer entering a freshly-opened bleaching-powder chamber to an oil-pan, even after the oil has been run off, and the pan cooled down. There was no task in the works more thoroughly abhorred than that ten minutes to half an hour, occasionally longer, during which, with the man-hole open, the workman was raking and poking between the radii of the fans to clear and find the outlet. With this now happily occasional exception, and for the few minutes during which the hot oil is being transferred from the pan to the tanks, this method of oil-boiling produces no disagreeable smell in the vicinity, the fumes being carried away with the surplus air pumped through the oil, and perfectly consumed, so far as noxious odour is concerned, in the furnace of the boiler. Members of this Society have frequently the opportunity of witnessing the efficacy of the operation of this process during some of the lectures delivered here, the air of this hall being kept free from troublesome fumes by a similar arrangement. From this paper the chemical questions involved must be, for the most part, excluded, as it would be scarcely possible for me to enter far into the subject without betraying confidence, the driers used, and their *modus operandi* being essentially connected. I may state, however, that the air does not play the part which many have assigned to it, and does in reality effect nothing towards making the oil a drying one. I have boiled linseed-oil with air alone, but without driers, for three days consecutively, keeping up a high temperature the whole time, and the resultant boiled-oil has taken precisely the same time to dry as the raw oil from which it was prepared. The body, however, had so much increased that the consistency was more that of a varnish than an oil.

If oil be subjected to heat alone for the same space of time, without any air except such as comes in contact with its surface, there is no such increase in consistence as in the former case; the oil simply becomes more greasy, has less difficulty in penetrating capillary tubes (as, for instance, those of paper, plaster, etc.) than it previously had, and has decidedly less drying powers. The oil which has been boiled with air is less greasy, and has a greater consistence. To sum up the process in a few words, I think we show we have the means at hand of meeting all the requisites which were stated to be necessary. The close apparatus in which the work is performed secures the manufacturer alike from annoying his neighbours and injuring his own men. The air and heat secure a sufficient amount of body. The driers produce any required shade of colour, the time of drying, *i. e.* about six hours in summer and eight hours in winter, according with the old standard of drying power. Oil can be made to dry in much less time, but this is not considered to be desirable. The mechanical appliances reduce the time of the operation to about one-fourth of that which in former years was thought essential. In the ordinary working day, starting with cold oil and a cold boiler, two batches, of two tons each, can be boiled without causing undue driving of men or machinery.

Before leaving this part of the subject it may be as well to note, that for boiled-oil which has to be exported, long experience has shown that it is advisable in all cases to add to each barrel or drum of boiled-oil a small proportion of raw oil. After a one or two months' voyage the oil becomes brighter than it was when first shipped, and the risk of becoming what is called "fatty," and not free enough in working, is thereby avoided. For a three months' voyage, one gallon of raw linseed may be added to each four gallons of boiled-oil with most beneficial results, particularly if the boiled-oil be anything under one month old.

Varnishes.

As you all know, the main uses to which varnishes are applied are, to protect the material over which it is spread from atmospheric influences, accidental rough usage, etc.; to bring out and display more fully the varying texture of different woods; and, finally, to give a fine gloss or appearance of polish to the surfaces to which it is applied. As commonly constituted, an oil varnish (and with these alone I propose to deal) consists of some hard gum dissolved in linseed oil. This is the substance of the varnish, the two being re-dissolved in turpentine to afford the means of spreading them out in thin layers. As far as regards the ultimate value of the varnish, the turpentine is merely so much waste material. It may, if it be of inferior quality, injure the varnish with which it is mixed, but, however good it may be, it can do nothing to benefit or improve a varnish which itself is in reality nothing but the mixture in various proportions of some one or more hard gums in linseed oil.

For the convenience of better understanding the *rationale* of the mode of procedure, it will be well if we commence our observations at the end instead of beginning of the process.

Turpentine, being applied for the purpose of thinning down the body of the varnish, and that body being, when cold, almost solid, has to be added whilst the mixture of gum and oil is still hot. The heat causing an increased evaporation, and consequently a loss of turpentine, the temperature is allowed to get as low as can be, consistently with a perfect and complete admixture of the spirit with the matter being secured. This is, to some extent, contrary to old-fashioned notions, but the varnishes resulting from mixing in the turpentine at a high temperature and at a low one being identical, the loss of so much evaporated material is not now taken as an essential part of the process. We have also one less risk of fire, since the whole varnish is now removed far from any fire, and out into the open air when practicable, before the turpentine is added. The quantity of turpentine required under these circumstances is much less than that stated in the various published recipes for varnish making. Enough is commonly added to bring the whole mixture to a consistence a little stiffer than linseed-oil. The loss by evaporation, whilst clearing and ageing in tanks, previous to its being sent out, gives it the amount of body which you are accustomed to see it have. The next thing to consider is the body of the varnish. Time would not permit me to give a complete description of the various gums which are or may be used; I can do no better than refer you to Mr. Neil's paper for information on this part of the subject. There is one gum, however, which has come very largely into use since his time, and that is the "kauri," New Zealand gum. It is rather dull in appearance, but it is tolerably hard, and melts at so low a temperature that the dust and chips made by cleaning the outside of large pieces can be utilized by a skilful man, without the gum being coloured by the carbonization of the woody matter in it. The varnish made from the better qualities of kauri have a very good gloss. When dry, they are pale in colour; dry quickly, and are not so liable to crack when exposed to the sun as better varnishes. After a few months' exposure to wet, however, the whole of the gloss disappears, and, though the protecting surface remains, it becomes, through its abrasion, a harbour for the dust and dirt, and is thus rendered far from ornamental to the place of its attachment.

The temperature at which the mixture of gum and oil intended to be used melts is now recognized as forming a basis for the temperature to which the oil is to be heated previous to the introduction of the melted gum, the whole running, when the two are fairly incorporated, being also kept much under the degree of heat which was formerly considered necessary. In fact, it is in this respect that the present mode of varnish-making chiefly differs from the modes formerly employed, the greatest care being now taken to keep the temperature throughout the process as low as is consistent with perfect admixture of the several ingredients.

The next point to which I shall direct your attention is the apparatus used for the modern process of varnish-making. In the first place, iron vessels generally take the place of copper ones for all common varnishes, the bottom of the gum pots alone remaining copper, as heretofore. The lower temperature employed is found not to affect the metal, and the introduction of impurities from that source is no longer feared.

In the next place, instead of heavy copper stirrers, light thin plates at the end of the rods are used to cut the gum, etc., the greater velocity with which they can be manipulated securing more perfect mixing than of old.

In the third place, a tramway is laid down from the furnace in which the mixed gum and oil is heated, which usually runs from the shed into the open air. If, therefore, from any accident the mixture takes fire, it can be at once removed to a place of safety, where it can be put out at more leisure.

The boiling-pot, which holds about 100 gallons, has a closely-fitting conical cover, which, if it can be put on, at once extinguishes the flame if it be not too far ahead. The last improvement has only recently been introduced, and is not yet generally adopted. Two galvanized iron shafts are erected side by side; one corresponds with the gum pot, the other with the boiling-pot; the upper end of these shafts alike communicates with the main furnace shaft. The lower ends are fitted with caps, which are so balanced by counterpoises that they can be slid up or down their respective columns. To these caps heads are attached at right angles, which can be brought over, and which fit closely on to the gum pot and boiling-pot respectively, and, when in that position, have free communication with the chimney-shaft. The front of each hood is cut away and fitted with a diaphragm, slit in such a manner that the contents of the pots can be stirred, and is removable when it is desired to see into them.

The advantages of this arrangement are obvious without further description; in place of the workmen being annoyed by the dense and pungent vapours which escape from the heated gum and oil, the whole are removed, and nothing whatever comes into the air of the shed except at the time when a pot of the gum is being tilted into the boiling-pot, or when the whole has to be removed into the air. The reduction of smell, as regards the neighbourhood, is so great, that in the comparatively rare intervals when a disagreeable vapour does come off, the air of the yard mixes with it sufficiently to neutralize the effect exterior to the works. This last improvement is due to Mr. Bewicke, of Hackney Wick, who, in consequence of a disastrous fire at his works having been caused in a great measure by the men being so suffocated with the fumes from the boiling-pot that they were unable, when it took fire, to extinguish it in time, has been impelled to seek for such more perfect appliances as would bring the whole system more under control than had previously been the case. I think you will agree that the plan deserves to succeed, and from the experience it has already had, I believe it will do so. Old varnish makers, standing at the furnaces when they are in full operation, seem at first almost at a loss to know what stage of the process they are at, from the want of their accustomed choking miasma.

Discussion.

The Chairman, in inviting discussion on the subject, said, if any members of the trade were present, who could furnish the meeting with any of the information which it would seem was rather kept secret, it would, no doubt, be of great advantage.

Mr. Tinne said he had hoped some practical man would have made some remarks on the subject, which he thought would be of great value. It was one very interesting to him, as he had seen abroad, especially in Holland, the beautiful character of what was there called porcelain painting, and he believed its great merit arose from some particular purity in the preparation of their boiled-oil and varnishes. He had been specially anxious, in the painting of his own house, to apply that same beautiful white porcelain painting which he had seen in Holland, but as yet he had not seen anything of the kind in this country. Allusion had been made to this improved process having originated in Germany, and no doubt Mr. Vincent was aware that the same thing existed in Germany as he had alluded to in Holland, and which might be noticed even on the Dutch ships which came to this country. He should much like to see the same kind of thing introduced here, for, unfortunately, what was called porcelain painting generally turned very yellow in a short time. He could only ascribe this to either ignorance on the part of the workmen, or impurity of the materials employed; and he hoped, therefore, that some improvement would soon be made.

Mr. Nicholson said, with reference to what had just been remarked about oil not being produced in this country capable of keeping the colour of the paints used in its original brightness, it was well known in the trade that there was an oil almost colourless, which was used largely by decorators for the finer class of work. It was an oil which had not been heated in any way, but simply oxygenated, and it had a powerful drying tendency, almost equal to that of boiled-oil; and if Mr. Tinne would confer with any decorator of note, he would tell him that that oil was in constant use. He had been much struck with the low temperature referred to by the lecturer in the boiling of oil, which he thought was about 260 degrees, and that the oil then showed no fatty tendency. It was, however, well known in the trade that oil might be boiled up to 600 degrees without showing any such tendency; in fact, that was the ordinary heat to which it was subjected in the process of trial before used for varnish-making. An oil would hardly show its impurities at a less temperature, certainly not under 500 degrees; at all events that was the opinion of the trade. With regard to varnish-making, the method described seemed to him somewhat of a primitive nature, for there was a process in common use whereby the whole of the vapour arising from the oil-pot and from the gum-pot was wholly absorbed and condensed into liquid, not passing into the chimney at all.

Mr. Vincent said he had great pleasure in agreeing with what had been said by Mr. Tinne with regard to the character of Dutch and German paintings; and it was really the fact that the oils which were boiled abroad had that characteristic which had been spoken of. They were, as a rule, paler than oils boiled in England, and, having no driers dissolved in them, they did not deteriorate the colours with which they were mixed, and thus the maximum of brightness was attained. He supposed the last speaker had referred to what was generally called "French oil varnish," which was a thing which had been known in the trade for the last thirty or forty years for the purpose of mixing with pale colours, and for producing very lightly coloured delicate paints. What he aimed at was this. There were a large number of persons in the trade who were not aware of the great advantages of using these pale oils, or otherwise there would not be so much oil boiled of such a dark colour. There was a sample on the table darker even than that which he had shown on the screen, and that was boiled especially to the order of a large consumer, who would have oil of that colour and character, and who used about a ton and a half per week at this time of the year. If there was not a demand for these dark-coloured oils they would not be produced. Mr. Nicholson's other remarks were in accordance with what he had already stated, that there were a great many processes in use which were not commonly known. He himself could only describe what passed under his own observation, the varnish and oil trade being, as he had remarked, a secret one. Mr. Nicholson had not stated the particulars of the process he had mentioned for removing the vapours arising from the gum and oil-boiling apparatus, and even the one he had himself described had only become known to him within the last few weeks, and he had had a good deal of experience. It was simply because of these processes being kept secret that people who would be very ready to adopt improvements, and so avoid being troublesome to their neighbours, and at the same time be able to produce a better article, were not able to do so; and every one had to discover for himself what other persons perhaps had long been practising. The Society of Arts had been instrumental in throwing light upon some of these dark doings many years ago; and if his paper, imperfect as it was, had the effect of drawing attention to the subject, and inducing those who had more knowledge and experience in the matter to come forward and make known the results of their experiments, all the purposes he had in view would be answered.

Mr. Nicholson said he should have much pleasure in showing Mr. Vincent over his manufactory if he had any disposition to see it.

The Chairman then proposed a vote of thanks to Mr. Vincent, which was carried unanimously, and the meeting separated.

Parliamentary and Law Proceedings.

The Serious Charge against a Chemist at Rotherham.

On Monday last, Mr. William Collinson, chemist and druggist, Masboro' Bridge, was brought up on remand at the Rotherham Police Court, charged with having caused the death of Eliza Utley. The evidence given on this occasion was principally a recapitulation of that given before the coroner, and printed last week in this Journal.

Mr. Whitfield, who represented the prisoner, argued that although under all the circumstances of this case, supposing that all that had been stated by the witnesses and the dying girl herself was believed implicitly, technically and legally it might amount to the crime of murder, he would venture to say that there was not a jury to be found in this country which would, under the circumstances of the case, find the accused guilty of murder. The coroner paid very great attention to the evidence adduced in the case, and there was no more evidence adduced before the bench than there was adduced before the coroner, and he (the coroner) found it his duty to tell the jury that, according to his judgment and experience, it would be competent for them to find a verdict of murder, but he would not recommend them to do so. Mr. Whitfield contended that the medical evidence made out nothing whatever against the prisoner, and that it was against the rules of evidence that a declaration made by a person in the absence of the accused should be admitted as evidence. He said that the statement was made at the eleventh hour under the extreme pressure of circumstances, the deceased having to account to her parents for the state she was in, and was not to be depended on. Deceased stated that she had been to Mr. Collinson, and Mr. Collinson said that was perfectly true, not for the purpose she had alleged, but for the ordinary one of relieving her from a pressure of water. The charge of murder was totally out of the question both as a matter of fact and as a matter of practice. The coroner knew that, and said that the charge against him was that of manslaughter, and he (Mr. Whitfield) thought that the Bench would come to the same decision.

The charge and the usual caution were then formally read over to the prisoner, who in answer said, "I only wish to say that I am entirely innocent of the charge."

The Chairman said, after a few minutes' consultation, that the Bench considered they had nothing to do with what the jury at the assizes would do. It was their duty to commit him on a charge of murder to the assizes.

There was much sensation in court at the close of the Chairman's remarks.

Mr. Whitfield then applied for bail.

The Chairman said the Bench had already consulted on that point, and had come to the conclusion that on such a serious charge bail could not be granted.

Censure of a Chemist by a Coroner.

An inquest was held on Thursday, September 21, at the Wheatsheaf Inn, West Orchard, Coventry, before T. Dewes, Esq., coroner, on the body of a woman, apparently about sixty-four years of age, whose name was not known. From the evidence it appeared that the deceased had been staying at a lodging-house kept by James Doogan. She had not complained of ill-health, but looked rather delicate, and had a cancer in her cheek. On Wednesday night she went to bed as usual, and on Thursday morning was found dead in bed with her clothes on. A half-ounce bottle of laudanum was found in the pocket of the dress worn by the deceased. The bottle was quite full, and bore the label* of Mr. Field, chemist and druggist, Coventry.

Mr. Edgar Overton and Mr. Shorter, surgeons, having made a *post-mortem* examination, gave evidence to the effect that the deceased died from serous apoplexy, produced by disease of the liver and left lung and the cancer, and the jury returned a verdict accordingly.

The coroner sent for Mr. Field, who appeared and admitted that the laudanum had been supplied from one of his shops. In answer to the coroner, Mr. Field said he did not think the bottle held more than enough laudanum to poison two persons. He also admitted that he had not registered the sale of the laudanum.

The coroner severely censured Mr. Field, and told him that it was a fortunate thing for him that the evidence went to prove that the deceased had not died from taking laudanum, otherwise the verdict would have been a very unpleasant one as far as Mr. Field was concerned. The coroner said that it was contrary to law for any chemist to sell poison without registering it.—*Coventry Newspaper.*

Female Apothecaries.

We have been favoured with the following paragraph from a local newspaper: "On Tuesday, an elderly woman, named Barker, residing at Norfolk Villa, Milton, went to the shop of a Mrs. Lashmar, and asked for threepence' worth of tincture of rhubarb, which she partook of

* We learn upon inquiry that the bottle was also labelled with the word poison, according to the requirements of the Pharmacy Act, and that the woman was cautioned in reference to taking it.

in the shop, and was supplied with a second dose which she said was for her son. Upon arriving home the same was administered to her son. Shortly after partaking of the supposed rhubarb, they both became very drowsy, and the symptoms becoming suspicious the neighbours at once communicated with police constable Pemberton, and Mr. Firman, surgeon, of Harmer Street, was quickly in attendance. It appears that instead of the unfortunate recipients of the apothecary's skill partaking of syrup of rhubarb, they had had administered unto them each three-quarters of an ounce of virulent poison—laudanum. Wet towels were applied to their heads, and after vomiting a great deal they were restored to consciousness, and are now progressing favourably."

Reviews.

Domestic Botany: an Exposition of the Structure and Classification of Plants; and of their Uses for Food, Clothing, Medicine, and Manufacturing Purposes. By John Smith, A.L.S., Ex-curator of the Royal Botanic Gardens, Kew. London: L. Reeve and Co. 1871.

We regret to have to speak depreciatingly of a work by one who has done so much useful work as the author of this book. We must, however, enter our protest against the publication of a scientific work so full of inaccuracies and absolute errors as is the first part of this volume. It is stated in the preface that the proof-sheets have been revised by two very competent gentlemen. This statement, however, can hardly apply to the part of the work of which we are now speaking. We object to the coining of such words as "rhizomat," "frutlet," and "thyclad," which answer no useful purpose, and can only bewilder the reader. We object still more to the use of such forms as "phyllodæ" and "involucræ" instead of "phyllodia" and "involucra" (in the plural). But yet more objectionable is the introduction to the botanical student of inadequate or absolutely incorrect definitions. We find, for instance, a "cyme" described without any allusion to the special centrifugal character of that mode of inflorescence, which may be found in any ordinary text-book. The greatest offence, however, is the definition of the pistil of a plant as comprising the style and stigma only, to the exclusion of the ovary, which any first year's medical student might have corrected. And yet this occurs three times!—at p. 39, "on the removal of the calyx, corolla, and stamens, the pistil will be seen seated on a round knob, or more or less elevated column called the ovary or germen;" at p. 47, "the pistil or pistils, there being often more than one in a flower, is seated on the ovary;" and at p. 57, "an ovary, with its pistil, is termed a carpel!"

When we pass from the first to the second part of the work, "The Families of Plants systematically arranged, with a description of their characters, properties, uses, etc.," we find the author much more in his element. There is collected here a very large amount of information, arranged in a convenient form, with respect to the various plants comprised in each Natural Order of flowering and flowerless plants that are useful for food or clothing, or for any of the various purposes incident to civilization. Thus, under the Order Leguminosæ, upwards of eighty species are enumerated, each of which is of some economical importance, and their properties and uses described. This portion of the work is so complete, and so valuable as a book of reference as to the various useful products derived from the vegetable kingdom, that it is the more to be regretted that the early part is so inaccurate, and so hastily put together. The volume is illustrated by a number of coloured drawings, which add greatly to its attractiveness.

Handbook of British Fungi, with full Descriptions of all the Species, and Illustrations of the Genera. By M. C. Cooke, M.A. 2 vols. London: Macmillan and Co. 1871.

With the spread of the study of natural science, not only does it become inevitable that the whole range of the vegetable kingdom is beyond the powers of any single man, however industrious, but specialists are obliged to devote themselves to particular departments, even of phænogamic or of cryptogamic botany. The number of described species of British fungi alone is considerably larger than that of our flowering plants; and since the most recent handbook in existence, the Rev. M. J. Berkeley's, is now thirty-five years old, the great advances made since that time in the knowledge of this class of plants has rendered a new one absolutely necessary to the mycologist. We are, therefore, very grateful to Mr. Cooke that he has added to his labours in cryptogamic and microscopic botany, so well known to readers of this Journal, the publication of the volumes before us. Although the author has been assisted by all the other leading English mycologists,—Mr. Berkeley, Mr. Currey, Mr. Broome, Mr. Worthington Smith, and others,—the labour of writing fresh, accurate, and yet terse descriptions of 364 genera and upwards of 2800 species, must have been very great. With regard to the manner in which the work has been performed, we have nothing but commendation to award. The descriptions are clear, neither too short nor too long, and contain just the information one wants about each species. Mr. Cooke has not attempted any originality in classification, following that of such standard authorities as Fries and the Rev. M. J. Berkeley. In his subdivision of the huge and difficult genus *Agaricus* he has adopted the arrangement of Mr. Worthington Smith, who has paid so much attention to the higher fungi, and whose analytical key of the subgenera is also reprinted. If we were to make the least criticism, it would be that some phrases are occasionally used with a certain vagueness; thus we are sometimes left in doubt whether by "agaric" is meant a member of the Order *Agaricini* or of the genus *Agaricus*. There is a coloured frontispiece, and a small woodcut to illustrate each genus, admirably drawn by Mr. W. G. Smith. The very low price at which the book is published is another item which makes it indispensable to the library of all botanists, and especially of all lovers of fungi.

VACANCIES AND APPOINTMENTS IN CONNECTION WITH PHARMACY.

The Editor will be glad to receive early notice of any vacancies of pharmaceutical offices connected with public institutions, and likewise of appointments that are made,—in order that they may be published regularly in the Journal.

APPOINTMENT.

Mr. John S. Cape, Associate of the Pharmaceutical Society, has been appointed by the Admiralty in charge of Medical Stores at the Royal Naval Hospital, Hong Kong.

The following journals have been received:—The 'British Medical Journal,' Sept. 23; the 'Medical Times and Gazette,' Sept. 23; the 'Lancet,' Sept. 23; the 'Medical Press and Circular,' Sept. 27; 'Nature,' Sept. 21; the 'Chemical News,' Sept. 23; 'English Mechanic,' Sept. 22; 'Gardeners' Chronicle,' Sept. 23; the 'Grocer,' Sept. 23; the 'Journal of the Society of Arts,' Sept. 23; the 'Chicago Pharmacist' for September; the 'Yorkshire Post and Leeds Intelligence,' Sept. 20; 'Rotherham and Masbro' Advertiser,' Sept. 25.

Notes and Queries.

**** In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[280.]—DISPENSING.—For potass. hydr., I should think, without a doubt, potassii iodidi is intended, the dose being only 1·25 grains in excess of the maximum dose of the P. B., the caustic potash being never given internally, except in the form of liquor potassii.—S. NEWBURY, *Medical Hall, Dorking.*

OINTMENT CONTAINING MUCH WATER.—The following recipe was recently handed to me to be filled:—

℞ Pyroligneous Acid,
Sulphur, each 4 oz.
Calomel, 60 grs.
Red Precipitate, 40 grs.
Spt. Turpentine, 1½ oz.
Lard, 4 oz. M.

I first intimately mixed the calomel and precipitate, then by degrees the sulphur, the turpentine, and finally a small portion of the lard. I now added a little, say two fluid-drachms of the acid, but entirely failed to get a mixture. As the acid is largely composed of water, the object was to dispose of the latter so that it might not interfere with the mixture. This was done by adding to the salve in the mortar a little wheat flour, with perfect success, after which lard, flour and acid were added alternately until the ointment was finished, leaving out of it as much lard as flour had been substituted. Four hours afterward, the ointment not having been called for yet, and the weather being very warm, it was found that some of the lard had melted, and was floating on the top, but readily mixed with the ointment again on making use of a spatula, but no part of the acid at any time separated from it.—JOHN H. EHLERS *in the American Journal of Pharmacy.*

THE CHEMISTRY OF TAKING OUT IRON-MOULDS.—Although the routine method of doing this is familiar to every chemist, the chemical reactions involved are by no means generally understood, and therefore a brief account of them may not be unacceptable.

My attention was first called to the subject while testing the comparative efficiency of three familiar solvents of ferric oxide, viz. hydrochloric acid, oxalic acid and quadroxalate of potassium—the sal acetos.

I was surprised to find that the latter, which I had regarded as most eligible merely for its convenience in application, was superior also in solvent power. When hydrated peroxide of iron is treated with a strong hot solution of sal acetos, in the proportion of two equivalents of the latter to one of the former, carbon dioxide is copiously evolved, the oxide is dissolved, and at the same time chiefly, if not wholly, reduced to the ferrous state.

The resulting solution is yellowish-green in colour, yields a well-marked precipitate with potassium ferridcyanide, and appears to contain ferrous oxalate and neutral potassium oxalate. The following is the equation:—

$$Fe_2O_3H_2O + 2KHC_2O_4H_2C_2O_42H_2O$$
$$= 2FeC_2O_4 + K_2C_2O_4 + 2CO_2 + 8H_2O.$$

The same result followed when the oxide was acted upon by a strong solution of oxalic acid at a boiling heat, but less quickly, moreover the resulting solution was of a deep yellowish-brown colour, and contained more ferric salt.

Three equivalents of oxalic acid to one of oxide were employed, as in the following equation:—

$$Fe_2O_3H_2O + 3H_2C_2O_42H_2O$$
$$= 2FeC_2O_4 + 2CO_2 + 10H_2O.$$

Knowing that a mixture of sal acetos and cream of tartar is sometimes sold as salt of lemons, I next tested the solvent power of this combination.

Taking as my guide the proportions employed in making the ferrum tartaratum of the Pharmacopœia, I compared the action on ferric oxide, of boiling solutions of acid tartrate of potassium, sal acetos and of a mixture of the two.

Only a small portion of the oxide was taken up by the acid tartrate either alone or combined, and the equivalent quantity of ferric oxide was dissolved more rapidly by the sal acetos alone.

Experiments performed upon black oxide of manganese showed that it, like ferric hydrate, was dissolved by hot solutions of oxalic acid and sal acetos, but reprecipitated as flesh-coloured or buff manganous oxalate, carbon dioxide being given off; the following equations show the reactions:—

$$MnO_2 + 2KHC_2O_4,H_2C_2O_42H_2O$$
$$= MnC_2O_4 + 2KHC_2O_4 + 2CO_2 + 6H_2O.$$

$$MnO_2 + 2H_2C_2O_42H_2O = MnC_2O_4 + 2CO_2 + 6H_2O.$$

Similar experiments with mercuric oxide failed to give any satisfactory result.

The practical inference is that the compound known as sal acetos is by far the best agent for removing either iron-moulds or the disfiguring brown stains produced by Condy's fluids.—J. F. BROWN.

[285.]—SYRUPUS CROCI.—"*A. D.*" wishes to know if any reader has tried the American receipt for Syr. Croci, given page 707 (J. W. Kennedy), and if so, what has been the result?

[286.]—DISPENSING.—I should like to hear the opinion of some of your readers about the dispensing of the enclosed prescription, and what appearance it should present.—GEORGE ELLIS.

℞ Spt. Ammon. Co. ʒss
Liq. Ammon. Acet. ʒij
Quinæ Sulph. gr. x
Liq. Morph. ʒj
Spt. Ether. Nit. ʒiss
Acid. Citric. ʒj
Potass. Bicarb. ʒiss
Mist. Camph. ℥iij
Inf. Gentian. ad ℥vj.
M. ft. mist.
℥j tertia vel 4tis horis.

[287.]—HOTCHKISS' OIL OF PEPPERMINT.—Some years ago I used to buy H. G. Hotchkiss' ol. m. pip. in original bottles, which would perfectly dissolve in s. v. r. 56 o. p. I cannot now procure the same article. That I have lately purchased produces a very milky liquid. This I presume is the result of adulteration with a fixed oil. Can any one tell me how I can procure the genuine article? I shall be glad to learn the experience of some of my brethren in this respect, and how the turbid liquid can be clarified, for ordinary filtration through paper is useless.—PHILOS.

[288.]—VEGETABLE PARCHMENT.—"*Ferrum*" would be much obliged for full particulars for the manufacture of vegetable parchment.

[289.]—SILVERING SOLUTION.—"*Ferrum*" also asks for a recipe for a good silvering solution that will not tarnish.

Correspondence.

**** No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Our Evening Meetings.

Sir,—The opening of a new Session brings before us the return of the monthly evening meetings, together with their ups and downs, success and failure, animation and dulness.

These meetings have always seemed to be *the* weak point in the annual *résumé* presented to us by our worthy Presidents at the close of each official year. From the time of Jacob Bell to the present day, lamentation has followed lamentation, expressed or implied, with unwavering regularity, until the incubus appears to be regarded as an evil to be endured, rather than a difficulty to be overcome.

With the hope of eliciting expressions and practical suggestions from other friends, which may possibly lead to some decided improvement, I venture to bring before your readers opinions which I have long entertained upon the subject.

Two fundamental objections to the present mode of arranging these meetings present themselves to my mind, viz. the time at which they are held, and the subjects chosen for the evening's engagement; vital points, striking at the very root of their existence, and yet I humbly submit radically wrong.

The time at which they are held.—Upon this point I speak as one living beyond the shadow of 17, Bloomsbury Square, but yet not beyond a reasonable walking or riding distance, as inclination may prompt; also old-fashioned enough to consider midnight strolls home undesirable. At present the orthodox time of commencing these meetings is half-past eight, but at the risk of being considered deeply heretical in my views, I venture seriously to question the policy of this established rule.

The argument used in support of the above time is, that an earlier hour would prevent many assistants attending who now avail themselves of the privilege. I must confess I do not precisely understand the ground upon which this theory rests. It certainly cannot be that early closing is so generally adopted in our business that our assistants are, as a rule, at liberty at that hour,—would that it were so,—but unless some such ground exists, I see no reason whatever for the argument. Either those who at present attend, do so in consequence of having that particular evening allotted them in the usual course of holidays, and which they choose thus profitably to occupy; or otherwise their masters allow them the privilege of attending independently of any such holiday. In the former case the evening is the assistant's own, and the difference of an hour would be of little consequence if he really appreciated the meeting; in the latter, I cannot but think that a master who would generously allow his assistant to leave home at half-past seven or eight (I am speaking of those residing at some distance), would as willingly do so at half-past six or seven, if necessary.

But further, we must bear in mind there is the return journey to be accomplished, which again occupies time. Can we expect these young men to be so wrapped up in the delights of pharmacy that no friendly greeting or quiet chat, or perchance some choice specimens, illustrative of the subject discoursed upon, will be allowed to detain them at the conclusion of the meeting? But should they succumb to any such temptation, by what hour may they be expected to arrive at Clapham, Brixton, Holloway or elsewhere? Omnibuses travel but slowly, cabs cost money.

Before leaving this part of my subject, I would add a word on behalf of the masters. Speaking from experience, and I doubt exceedingly whether I am alone therein, the present hour entirely precludes my attending these meetings, much as I sometimes desire to do so, for the simple reason that domestic arrangements would be upset in consequence of the absence of the head of the household. The hour of departure is of no importance, the hour of return is just the reverse.

On these grounds, bearing in mind the utter failure of past years, I would venture to suggest that at least a year's trial should be given to the following alteration. "That the chair be taken at half-past seven and vacated at nine."

The second point to which I desire to draw attention is,—

The subjects chosen for the evening's engagement.—Upon this head I shall be very brief, leaving it to the superior judgment of those more experienced in catering for those supposed to possess some small amount of scientific knowledge; but I must confess a weakness for desiring to see a little extension of the circle of our lecturers, beyond the confines of the Pharmaceutical Calendar. In so saying, I would not for a moment be understood to speak disparagingly of those gentlemen who are so well known to us all, and who take so active and praiseworthy a part in endeavouring to put life into these meetings, but at the same time I should greatly like to see the announcement of lectures or course of lectures by some of the "Stars of Science," upon subjects of general interest to members, but yet somewhat above the preparation of a concentrated iron mixture or blue pill,—things good in their way, but not sufficiently attractive to induce men to leave their homes or take an hour's walk to hear, when they will have the whole thing before them in the space of a few lines in the following week's Journal. Dr. Carpenter's lecture on "The Microscope and its Revelations" was a step in the right direction, and many, I venture to say, would gladly have availed themselves of the opportunity of hearing them, had it not been for the inconvenience of the hour.

But I must conclude, the importance of the subject being my excuse for having occupied so much of your space. Let the suggestions be at least considered; get out of the old time-worn groove; launch forth into fresh fields, and, I am bold to say, our evening meetings may yet be a success.

Edwin B. Vizer.

63, *Lupus Street, Belgravia South,*
September 26th, 1871.

Impurities in Chloral Hydrate.

Sir,—In a discussion on chloral hydrate at the meeting of the Pharmaceutical Association at Edinburgh, attention was drawn to certain impurities, which greatly invalidate the application of the remedy, and hopes were expressed that the matter might be inquired into. I had lately occasion to inspect large quantities of such impure preparation, partly made by foreign manufacturers, but partly also by an English firm. The impurity is exactly the same in both cases,—most likely a result of the manufacturing process, and ought to be capable of being remedied. The impure hydrate gives off dense, strongly acid fumes as soon as the bottle is opened; these fumes affect the eyes and the skin most severely, to such extent, that on manipulating with about a cwt. the epidermis of the operator's hands was completely destroyed.

I purpose sending to the evening exhibition next week a sample of chloral hydrate in this state, and also another which I have succeeded in depriving of the objectionable character above mentioned. The question naturally arises, whether the formation of the foreign compound cannot be avoided. It is not hydrochloric acid, as has been suggested, but an organic chlorine compound (perhaps chlorpicrine) formed together with chloral, and not resulting from a decomposition of the latter. I first was under the impression the fumes were due to a small quantity of chloral, not hydrated, the strong penetrating smell of which is somewhat similar, but solution in water does not take away the strong smell. In a short time I hope to be able to state definitely the nature of this impurity.

Fred. Versmann, Ph.D.

150, *Fenchurch Street, E.C., Sept. 26th*, 1871.

Pharmaceutical Nomenclature.

Sir,—The brother demon to the printer's devil is his compositor. *The Times* told us the other day that "one of the most prominent members of the present Government was kicked out of the camp of advanced liberalism." Imagine the wrath of liberals and the chuckle of illiberals all over the country on reading this statement, and the disgust of both sections on finding that their emotions had been excited through a wretched compositor using a *k* for a *p*; the gentleman had been picked out, not kicked—the compositor deserved the kicking. Then a poetic idea associated with "full blown roses" has been hopelessly destroyed by the words being printed "full blown noses." But such mistakes (there are many on record) are tolerably obvious. Not so one which occurred in my letter on Pharmaceutical Nomenclature which appeared in your last Journal. I am there made to raise the bogey I endeavour to overthrow, by the compositor having put only the first of three consecutive and associated sentences within inverted commas. I am made both to assert and to controvert a position illustrated by 1 and 1 making 3. Your readers will please extend the area embraced by the quotation marks in line 18 of my letter so that they shall not only include the annexed sentence "A nomenclature is only a system for the conveyance of facts" but also the two sentences which follow. JOHN ATTFIELD.

Sir,—When Professor Attfield gave me his list of proposed nomenclature, I instantly, and without a moment's reflexion, read off the column he suggested in correct contracted latin. By "correct" I mean such latin as would be accepted by the Medical Profession in their prescriptions. I therefore, in common with many others, thought the advocated nomenclature good, and likely to be useful. Whether it be an exposition of the latest chemical theories, or *is* common sense adapted to chemical facts, are points over which the Professor may make himself happy. The autumn work of a journalist is heavy, and I have no time between now and November to fight over shadows. JOSEPH INCE.

THE COUNCIL OF THE NORTH BRITISH BRANCH OF THE PHARMACEUTICAL SOCIETY.

Sir,—Mr. Baildon, in to-day's Journal, points out what appears to him to be a discrepancy in one of Mr. Fairlie's letters, but to my mind he has only shown his want of comprehension of the point at issue. As I understand the letter referred to, Mr. Fairlie implied that while in matters social good feelings had been shown and reciprocated externally—possibly having in his mind's eye the late reception of the Pharmaceutical Conference, and other meetings of a social nature, at which members of the trade belonging to the two cities met together—in matters pharmaceutical the Edinburgh brethren had shown an amount of injustice, or at least want of consideration towards other chemists throughout Scotland. My own experience, gathered from observation in both cities, corroborates this; and what I believe Mr. Fairlie wishes is that these external exhibitions of good will should take root in the pharmaceutical world, as well as in the social, in order that some lasting benefit might accrue both to the Society and the trade at large.

I think Mr. Mackay is at fault in accepting Mr. Fairlie's attack on the Council as a slur upon himself or his actions; and as for the supposed implication that the Council have benefited by the grants received from the parent society, it is entirely a gratuitous supposition.

It is well known here that the Committee of the Glasgow Association have refrained from asking a grant of money to help on their education schemes, because, as has been frequently reiterated by the members of the "Council of the North British Branch" in Glasgow, "That it was no use, Edinburgh gets so much money from London that the Council there would not listen to them." The result is, that Glasgow has been forced, to a certain extent, to be pharmaceutically asleep, while Edinburgh is receiving encouragement to prosper with their pharmaceutical education.

I hope that the present discussion will make matters take a turn for the better to all parties, particularly that Scotland may have her due from the London Council, as a distinct and separate body from the English pharmacists, and that Scottish chemists may have something to look to when they become members of the Pharmaceutical Society.

Glasgow, Sept. 23rd, 1871. PH. C.

Sir,—I can fully sympathize with Mr. Fairlie in the position he has found himself in this question, and admire the spirit with which he has struck at the root of the matter against such influence as it is known the members of this Council can command. The several gentlemen who have replied to him have taken a delight in parading before the readers of the Journal the fact that he has only recently become a member of the Pharmaceutical Society, but this, in my opinion, says the more for his fortitude; and I hope he will return the taunt in the manner the great Pitt did when taunted by Walpole on account of his youth, showing that though he has the misfortune to be a young member of the Society he has not the greater misfortune of having some crotchety and old-fashioned notions in his head which nothing evidently will eradicate.

Mr. Fairlie deserves the thanks of the "Outsiders" for having opened up a subject which may ere long, I hope, open up the doors of the Pharmaceutical Society to all desirous of entering it; so long as this self-elected Council is allowed to manage the affairs of the Society in Scotland as they choose, so long will the most active men, connected with the drug trade, remain passive on-lookers of what they can only term a "myth."

AN ON-LOOKER.

Edinburgh, September 25th, 1871.

ACTION OF HEAT ON PROTOPLASMIC LIFE.

Sir,—Holidaying accounts for my not seeing your issue of 2nd inst. till to-day, when the paper on "The Action of Heat on Protoplasmic Life" caught my earnest attention, because that was a subject of interesting discussion in my quarters here a few days ago, and in entire ignorance of the valuable experiments of Mr. Crace-Calvert.

At said discussion I brought forward a fact which you may think worthy of notice, as when attention is directed to the particular case abundant and important corroboration may be adduced.

The case I adduced was, that during the late civil wars in the United States my sister had charge of, in Mississippi, an hospital for the sick and wounded, and that one of the most dreadful things she had to deal with was the destruction of the germs of vermin in the clothes of the soldiers brought under her supervision and treatment. Ten hours' consecutive boiling in water failed to destroy these germs. Incubation seemed only to have been quickened, for in the act of drying, or shortly thereafter, vermin swarmed from the hems of the boiled clothes, and nothing short of a scorching heat applied over the hems, by means of a smoothing iron, destroyed the vitality of the germs.

Millport, Sept. 22nd, 1871. A. W. P. S.

THE DRUG TRADE IN CANADA.

Sir,—I shall feel obliged if any of your readers, either from residence in Canada or from knowledge of the country through other sources, can give me reliable information as to the state of the drug trade there.

I wish to ascertain exactly what is the usual rate of remuneration for assistants in drug stores or as dispensers to medical practitioners; whether or not the certificates of our Pharmaceutical Society are recognized; what success might reasonably be expected by a gentleman going into business on his own account; and also, whether or not the Canadian Pharmacopœia differs much from our own?

The *amor patriæ* is very strong in me; but as I know by experience that the condition of chemists in England, in a small way of business, is very wretched, I am desirous of finding in another land an adequate return for outlay of capital and persevering industry.

September 11th, 1871. JATEORRHIZA.

Schools of Pharmacy.—We have received a letter from Mr. Cooper, of York, suggesting that notices of the schools of pharmacy in the United Kingdom should be published in the PHARMACEUTICAL JOURNAL in a way similar to that in which the medical papers publish notices of the medical schools. We shall be glad to carry out this suggestion if those connected with provincial schools will favour us with information respecting them.

"*Truth.*"—The character is "Leaves alternate or opposite;" the latter word has been accidentally omitted.

"*Ignis Fatuus.*"—(1.) The fourth edition, published in 1851. (2.) No. (3.) The extracts may be taken from any part of the Gallic War.

E. T. F.—The works mentioned may be obtained through any respectable bookseller.

Lloyd Rayner.—The publication of your letter would raise questions which we do not think it is the province of this Journal to discuss. The report of the proceedings at the police court was taken, as stated, from the *Daily News*, and our remarks were based upon the statement made by your own solicitor.

"*Chemicus.*"—Your letters have been handed to the officers of the Conference, from whom you will probably hear at the termination of the vacation. A list of the works recommended by the Board of Examiners may be had by applying to the Secretary, 17, Bloomsbury Square.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. J. Edwards, J. Mackay, T. Cooper, S. W. R. Nevin, C. Umney, A. Shillcock, J. R. Summers, A. Field, W. H. Beaumont, J. B. B., E. H. S., "Truth," "A Minor Associate," "Scrutator," "East Wind," "Analno."

OIL OF ANDROMEDA LESCHENAULTII.*

. . . Early in 1867 Mr. M'Ivor requested me to examine an essential oil which he had obtained from a very common hill plant, the *Andromeda Leschenaultii*. I did so, and was enabled to identify the oil as methyl-salicylic acid, and almost identical with the Canadian oil of wintergreen.

Oil of wintergreen is an object of some slight commerce, being used in perfumery, and occasionally in medicine as an anti-spasmodic. The oil from this Indian source contains less of the peculiar hydrocarbon oil, which forms a natural and considerable admixture with the Canadian oil, and therefore is somewhat superior in quality to the latter. The commercial demand for the oil is not, however, considerable enough to make its occurrence in India of much direct importance.

It occurred to me in 1869 that methyl-salicylic acid would, however, under suitable treatment, furnish carbolic acid according to a decomposition described by Gerhardt. After a few experiments I was successful in preparing considerable quantities of pure carbolic acid.

The method of manufacture is as follows:—

The oil is heated with a dilute solution of a caustic alkali, by which means it is saponified and dissolved, methylic alcohol of great purity being liberated. The solution of the oil is then decomposed by any mineral acid, when beautiful crystals of salicylic acid are formed. These are gathered, squeezed, and dried. They are then mixed with common quicklime, or sand, and distilled in an iron retort; carbolic acid of great purity and crystallizing with the greatest readiness, passes into the receiver.

This acid is equal to the purest kind obtained from coal tar, and employed in medicine. I exhibited a specimen of it at the Neilgherry Exhibition in 1869. It, of course, possesses all the qualities which have rendered this substance almost indispensable in modern medical and surgical practice.

I had hoped, from the inexhaustible abundance with which the plant grows on the Neilgherries, that the carbolic acid from this source could be prepared at less cost than that imported. I have not yet had an opportunity of working on a large scale with an itinerant still, as would be necessary for its cheapest production; but from some calculations I have lately made, I am led to think it can scarcely be prepared for less than the price of that procured from coal-tar. The purest kinds from the latter source cost four shillings a pound; I estimate the cost of that from this indigenous source at from rupees 2. 8 to rupees 3. 8 (5 to 7 shillings) per pound *in this country*.

The carbolic acid from the same source has certain advantages over the coal-tar acid, consequent on its extreme purity. It is less deliquescent, and cannot possibly be open to the suspicion of contamination with certain other products of coal-tar which possess injurious qualities. This occasional suspicion, indeed, has led to the introduction of the costly thymol in France, as a substitute, in delicate cases, for carbolic acid.

In conclusion, I am led to the belief that it would not be advisable to prepare carbolic acid from this singular source, when the comparative cost shows that the gain must be very small or non-existent. But it appears to me well worthy of record, that should circumstances render the supply of the English product difficult or uncertain, as in the case of war, or the English price increase, a practically inexhaustible source exists in this country from which this indispensable substance, in its purest state, can be obtained at a slight enhancement of the present price.

* Extract from letter from J. Broughton, Esq., Government Quinologist, to the Secretary to Government Revenue Department, Fort St. George, dated Ootacamund, 9th January, 1871.

CERTAIN PROPERTIES OF THE TUTU PLANT (CORIARIA RUSCIFOLIA).*

BY H. G. HUGHES, M.P.S., HOKITIKA.

During the past year I have devoted my leisure to the investigation of the properties of the tutu plant, and communicated my results from time to time to Dr. Hector and Mr. Skey, who kindly assisted me with their criticisms. The following paper embodies a brief account of my experiments, which circumstances have unfortunately prevented my completing as I wished to have done.

About three-quarters of a pound of the fresh ground shoots were treated with successive quantities of distilled water slightly acidulated. After filtering and adding the acetate of lead in excess, it was submitted to the action of sulphuretted hydrogen, again filtered and evaporated to the consistency of an extract. This extract was well washed with successive quantities of alcohol, filtered, evaporated and ammonia added, when a precipitate resembling kermes mineral was separated (resinous matter). It was still further concentrated, distilled water added and again filtered from precipitate; evaporation continued, again treated with alcohol, filtered and evaporated to a syrupy consistence. On cooling, a few crystals formed with difficulty. This thick solution possessed very active properties, and a quantity of it, certainly not more than one-twelfth of a grain (I was scarcely aware of having tasted it), in five minutes' time produced a most disagreeably irritating sensation in the throat, extending to the stomach, with pain across the region of the stomach and accompanied by nausea. In a quarter of an hour's time vomiting came on, which continued more or less for two hours. Very unpleasant sensations continued for two hours more, when, after great flushing of the face, with all but intolerable heat, the effects passed away. Of course, not anything was taken to counteract the poison. On the addition of a little ether to the thick solution, a quantity of acicular crystals immediately made their appearance, but became redissolved as the ether slowly volatilized. The whole was afterwards shaken up with ether, the ethereal solution separated. Upon spontaneous evaporation, three or four drops of a fine yellow-coloured fragrant oil were left as residue. The fragrancy increased upon the application of a gentle heat. Upon evaporating the thick alcoholic solution, crystals of supposed alkaloid formed. These were redissolved and recrystallized until their solution in alcohol was perfectly colourless. During the final evaporation of an alcoholic solution, an accident

* Read before the Wellington Philosophical Society, November, 12, 1870.

occurred, and they were lost, having been burnt. The residue was black and charred (carbonaceous).

The experiment was made with the view of isolating an alkaloid. A resin was separated (the powder before mentioned); it was combustible, burning with a clear flame; also, a bright yellowish-coloured fragrant oil. This fragrant oil was also obtained by distilling the expressed juice of the fresh and succulent young shoots. It comes over with the water, rendering it very fragrant. A solution of sodium chloride added to this fragrant water (it being previously shaken up with a little potash) immediately curdles it.

About three ounces of leaves were exhausted by percolation with precipitate and benzine successively. The benzine solution contained nothing of importance. The alcoholic solution was treated in the same manner as that of the young shoots; it contained the fragrant oil, it was also poisonous, but when lime was substituted for the acetate of lead, no alkaloid was found, and altogether it was a most unsatisfactory experiment. I thought the principles were lost.

Three-quarters of a pound of the bark was next examined. It was in a bad condition, and had been taken off a part of the trunk of a tree near the ground; it had been submerged during a flood of the Hokitika river. This was treated in the same manner as the young shoots, with the exception that lime was used, but yielded nothing besides a trace of the fragrant oil and some resinous matter.

Some of the seeds of the fruit (three-quarters of an ounce), all that could be obtained, the season being so far advanced, were macerated in alcohol and evaporated. To this alcoholic extract a little powdered lime was added and mixed. It was then well washed with spt. vin., ether and chloroform in succession. Neither of the latter two yielded anything upon spontaneous evaporation. The alcoholic solution evaporated; the residue was treated with acid sulph. dil., filtered, and pot. carb. added in excess caused a flocculent precipitate. The solution separated, the precipitate was treated with alcohol and filtered. As the solution became more concentrated, a heavy olive-coloured oily fluid separated. Some shoots of the tree gathered 3rd December, 1869, yielded this oily fluid. It is of a most poisonous nature, half a drop administered to a terrier exciting most severe symptoms (vomiting and convulsions). After further concentration, ether was added, when a yellowish precipitate formed, the oily fluid separating of a clear olive-green colour. As the ether volatilized, the precipitate was redissolved by the alcohol; the oily fluid remained. Chloroform added caused a pure snow-white precipitate, which floated, the oil still remaining unaffected. It was then separated from the precipitate, dissolved in alcohol and filtered. Upon evaporating spontaneously, it deposited feathery crystals of a dingy colour (impure or contaminated with the oily fluid). Before all the alcohol had evaporated, chloroform always gave a pure snow-white precipitate. The crystals were extremely deliquescent. I thought this oily-looking fluid was a liquid alkaloid similar to conia. It was soluble in alcohol, but insoluble in both ether and chloroform. The alcoholic solution of this oily substance and white alkaloid possessed very energetic properties,—an all but inappreciable quantity bringing on, almost immediately, a very distressing suffocating sensation, and an unpleasant feeling of roughness and insensibility of the palate. Not any of the fragrant oil was found.

Respecting the opinion that the oily-looking fluid is a liquid alkaloid, and at least holds in solution a salt (supposed alkaloid), the following may tend a little to uphold it.

It is very remarkable that this oily fluid is perfectly insoluble both in ether and chloroform, and soluble in alcohol and a mixture of alcohol and water; and whatever the poisonous principle or principles may be, that slacked lime made into a thin cream with water instantly destroys it or them, with or accompanied by the evolution of ammoniacal vapour. The fragrant oil is soluble in ether and chloroform, and I imagine it to possess emetic properties only, as will be seen when treating of the antidote.

Moreover, a portion of alcoholic extract was mixed with distilled water introduced into a pint retort and heated in an oil-bath. The extract was fragrant, and as a consequence, the fragrancy of the essential oil passed over with the first quantity of water as was intended and was removed. When the extract thickened, a good heat being applied (350° to 400° F.), I found snow-white acicular crystals sublimed in a ring all round the neck of the retort, two inches from the stopper. Watching how they formed, I saw drops of oily fluid of an olive-green colour (the same oil apparently as that before mentioned), settling very curiously (as drops, I suppose owing to the repulsion of the glass from the high temperature employed, and the low degree of volatility of this oil), on the neck of the retort, which being very hot, these drops, as they slowly volatilized, left snow-white acicular crystals, and similarly to those before mentioned, extremely deliquescent, and very soluble in alcohol. Some were preserved, mounted and examined with the microscope, and I thought they were oblique rectangular prisms. As far as I was able to judge, these were exactly similar to those before described as having been lost. I imagine that the charring of the first ones, and the extreme deliquescence of these, altogether set aside the opinion of their being ammonium chloride, which was suggested to me by Mr. Skey. The crystals taken from the neck of the retort gave precipitates with the iodide of mercury and tannic acid respectively. An unused portion of the extract experimented upon, was treated with slacked lime (it was the first time that slacked lime was used), when strong ammoniacal vapour was discharged, and the extract became a solid mass. Suspecting the alkaloid, or whatever it was, to be destroyed, just as anticipated, although great and unusual care was used towards isolating the various principles, yet not a trace of anything was found, as was the case with the other portion subjected to distillation with water. It was from the consideration of this strange reaction that it occurred to me that lime would be of avail in cases of poisoning.

From another quantity of the shoots of the tree, crystals were obtained of a very mixed character, which gave precipitates with iodide of mercury, also the bichloride of mercury. These had a very peculiar taste, saline and bitter and very biting, and were poisonous, half a grain causing slight nausea and exciting symptoms similar to the oil, but milder.

In all my experiments, the ether, alcohol, chloroform, etc., used, were the commercial articles.

(To be continued.)

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Plumbi Acetas.—Oxide of lead is dissolved in acetic acid, used in slight excess, and the salt made to crystallize by evaporating the solution. Sugar of lead occurs in crystalline masses, having a sweetish astringent taste and an acetous odour; it is soluble in spirit and in water. [§ The solution slightly reddens litmus, gives a yellow precipitate (PbI_2) with iodide of potassium, and is precipitated white ($PbSO_4$) by sulphuric acid, acetic acid being set free.] It is hardly liable to any impurity.

Plumbi Carbonas.—Though of small importance pharmaceutically, carbonate of lead occupies, as a pigment, a very prominent position. It is made largely by a process which is but little varied in different countries. The principle upon which it depends is found in the fact that a mixture or compound of oxide and acetate of lead is converted by carbonic acid gas into a mixture of carbonate and neutral acetate of lead. Practically, metallic lead is exposed to the simultaneous action of acetic acid vapour, atmospheric oxygen and carbonic acid, with the assistance of a slightly elevated temperature. The carbonic acid is supplied very commonly by the fermentive decomposition of tan and stable manure; or sometimes by the combustion of coke or charcoal. It may fairly be supposed that the acetic acid and oxygen coat the metal superficially with a basic or oxyacetate, which, as soon as formed, is transformed by the carbonic acid into carbonate, and that this kind of action continues till the whole of the lead is converted.

White-lead is adulterated with chalk, sulphate of barium and other substances.

[§ Tests.—Soluble with effervescence in diluted acetic acid without leaving any residue. The acetic solution, when treated with excess of sulphuretted hydrogen, boiled and filtered, gives no precipitate with oxalate of ammonia.]

White-lead is a hydrate-carbonate, but varies in composition; it is often $2PbCO_3, Pb(HO)_2$.

Plumbi Iodidum, PbI_2.—Solutions of nitrate of lead and iodide of potassium are mixed together, and the bright yellow precipitate collected, washed and dried.

$$Pb(NO_3)_2 + 2KI = PbI_2 + 2KNO_3.$$

Although the Pharmacopœia directs the salts to be dissolved in water by the aid of heat, the solutions should be allowed to cool before mixing or the precipitate will sometimes be too distinctly crystalline. Iodide of lead may readily be crystallized from boiling water in scales which have the lustre and appearance of gold.

Plumbi Nitras, $Pb(NO_3)_2$.—An anhydrous salt, crystallizing in regular octahedra, which are usually opaque, and prepared by dissolving lead,—

$$3Pb + 8HNO_3 = 3Pb(NO_3)_2 + 4H_2O + 2NO,$$

or its carbonate or oxide in dilute nitric acid.

$$PbO + 2HNO_3 = Pb(NO_3)_2 + H_2O.$$

The solution gives the usual reactions of lead compounds and of nitrates.

DETERMINATION AND CHARACTERISTICS OF CITRIC ACID.

BY H. KÄMMERER.

Soluble citrates mixed with acetate of baryta, either hot or cold, produce a white amorphous precipitate, being $3\,BaO, 2\,C_{12}H_5O_{11}, 3\,Ho, + 14$ aq.

If, after precipitation, an excess of acetate of baryta be added, and the mixture heated in a water-bath, the precipitate becomes heavy and granular, it loses one-half of its water of crystallization, and has now the composition $3\,BaO, 2\,C_{12}H_5O_{11}, 3\,Ho + 7$ aq.

The presence of other organic acids does not interfere; the granular salt is absolutely insoluble in water, and citric acid may thus be easily determined. If the solutions are very dilute they must be concentrated by evaporation, after additions of acetate of baryta, or the precipitate will consist of crystalline needles containing only 5 aq.—*Zeitschr. für Analyt. Chemie*, viii. p. 298.

Inspection of Weights and Measures.—Under the Act 5 & 6 William IV. all persons are liable to have their weights and measures inspected who are proprietors of any "shop, store, warehouse, stall, yard or place whatsoever, wherein goods are exposed or kept for sale, or weighed for conveyance or carriage." A Bill for amending and consolidating the laws relating to weights and measures was prepared by the Standard Weights and Measures Department, and submitted to the consideration of the Government last session; the Bill, however, was not limited to consolidation with unquestioned amendments, but proposed the permissive introduction of the metric system, and was left among the "good intentions" of the Session. The Warden of the Standards observes that it deserves consideration whether the class of persons liable to inspection of their weights and measures should continue to be defined in the above terms; these are now construed as not including wholesale dealers, and it might be a matter of just complaint on the part of retail dealers that, while they are themselves subject to the visits of inspectors of weights and measures, the wholesale dealers from whom they must buy their goods are not subject to such inspection. The absence of authoritative instructions to the inspectors specifying more exactly the trades subject to inspection has led to many traders not having been subjected to it. For example, chemists and druggists, pawnbrokers, etc., using troy weights, have hardly ever had their weights inspected. An attempt has been made by the department to ascertain, with the aid of the census returns of 1861, the number and description of traders, manufacturers, etc., using weights and measures who are not liable to inspection under the existing law. A list has been made out from which it would appear that out of a total population of 29,000,000 in the United Kingdom in 1861, 1,333,679 persons were engaged in trades subject to inspection of their weights and measures, and 3,627,988 persons were engaged in trades and manufactures requiring the use of weights and measures who are not liable to inspection. Among the persons not liable to inspection are cotton, woollen, linen and silk manufacturers, tailors, blacksmiths, carpenters, farmers, dressmakers, coopers, cigar and tobacco manufacturers, candlemakers, copper manufacturers, engine and machine makers, flannel manufacturers, felt manufacturers, opticians, outfitters and clothes dealers, picture-frame makers, plated-ware manufacturers, saddlers, typefounders.—*Times*.

The Lemon-tree Disease.—Her Majesty's Consul at Messina reports that the disease of the lemon-tree continues its ravages, and nothing has yet been discovered to arrest its progress. Last year the oranges, but more particularly the lemons, were badly tainted, and a large proportion being unfit for shipment, were converted into juice or essence.

THE EXHIBITION AT THE EVENING MEETING.

In accordance with the intimation of the Council of the Pharmaceutical Society as to the exhibition of any articles of novelty, or otherwise, of special interest to pharmacists on the occasion of the Inaugural Meeting of the session, a space was set apart in the Society's museum for this purpose. Some of the articles exhibited were exceedingly interesting.

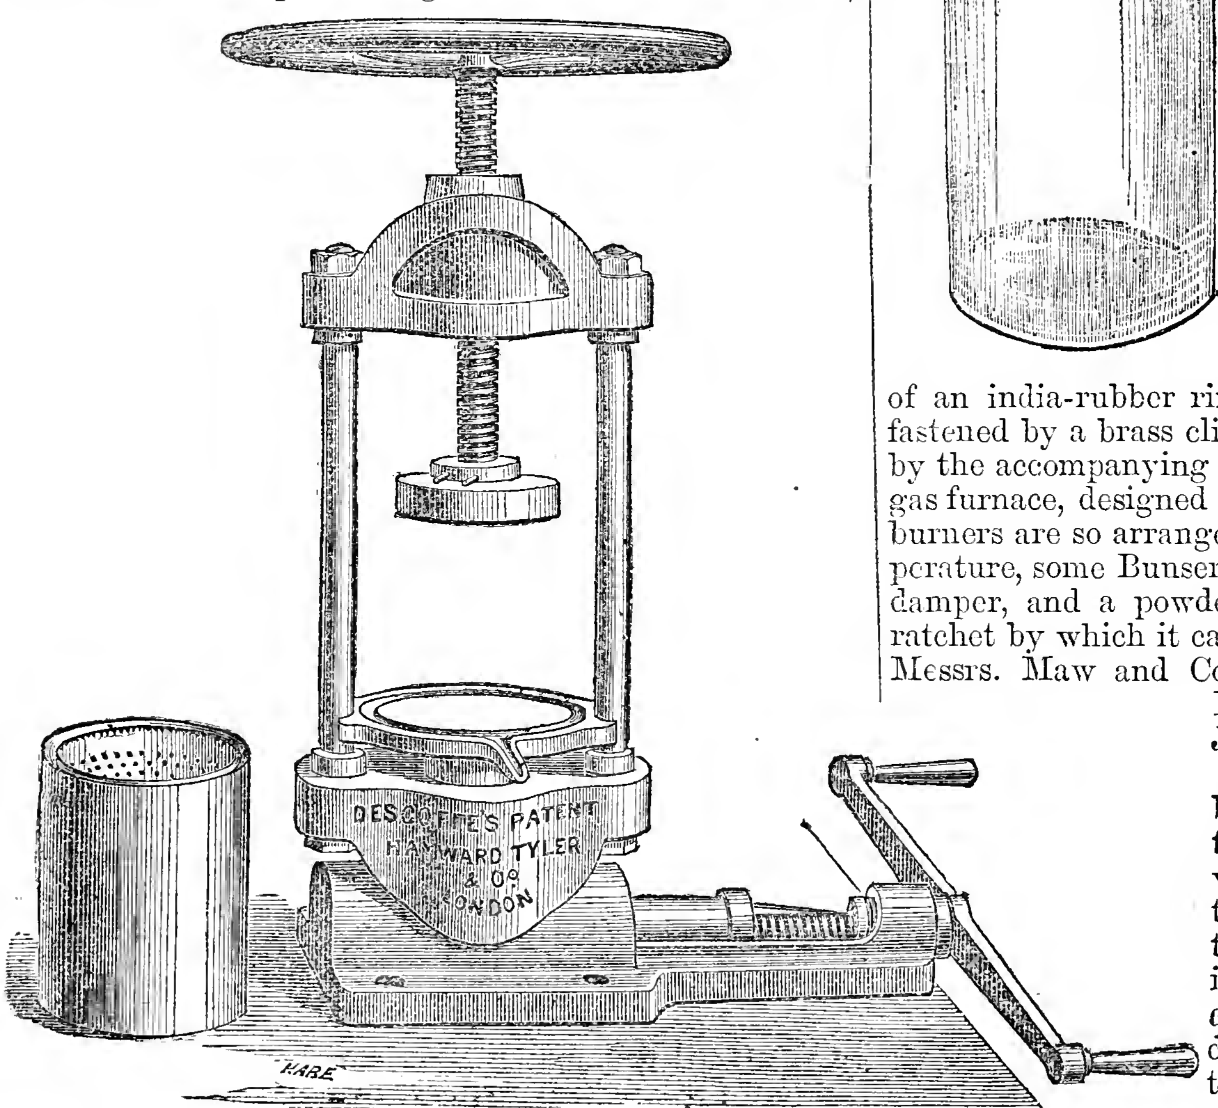
A principal feature was the exhibition of the donations presented to the museum since the last meeting of the previous session, a list of which will be found at p. 287. Prominent among these were the collection of Chinese materia medica, of more critical value than such collections usually are, since it includes the identical specimens described in Dr. Porter Smith's work recently noticed in this Journal; a few specimens of Indian drugs, principally officinal in the Indian Pharmacopœia; and the specimens of oil and carbolic acid from *Andromeda Leschenaultii*, prepared by Mr. Broughton. There was also a specimen of the much-lauded and much-abused condurango.

A specimen of the impure fuming chloral hydrate referred to by Dr. Versmann in his communication to this Journal last week, was exhibited by that gentleman; also specimens of the purified salt in crystals.

Mr. Williams sent for exhibition one of Fletcher's blowpipe lamps, manufactured by Messrs. Horne and Thornthwaite. In this the flame is delivered from a horizontal pipe, round which is coiled a small iron tube, ending at the mouth of the gaspipe. Through this air is blown, which is heated in its passage by two small Bunsen jets beneath.

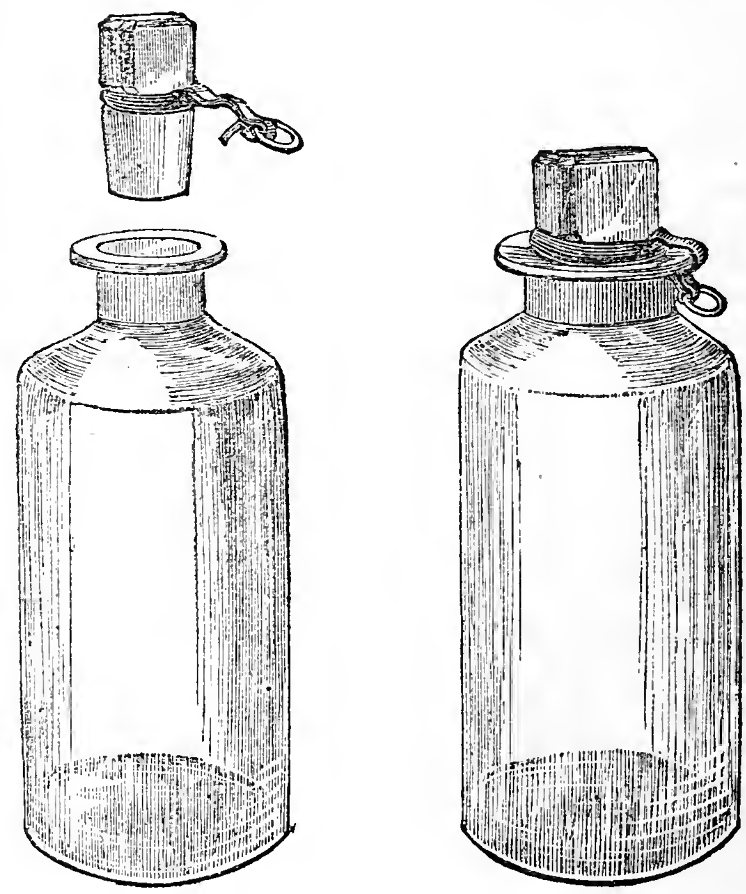
A Compound Hydraulic Press, suited to small laboratories, for extracting tinctures, etc. and for all purposes where hydraulic pressure is required (Desgoffe's patent), was exhibited by Messrs. Hayward Tyler and Co.

The press is provided with a circular table, round which is a groove conducting to a small spout in front. On this table is placed a galvanized iron double box,



8 in. diameter by 10 in. deep (shown standing by the side of the press), the inner casing being perforated with holes. The movable mullet of the press, worked by a powerful screw and hand-wheel, fits accurately into this box, and travels nearly its whole depth. When the box has been charged, the pressure is first applied with the screw. If moderate pressure only is required this will be sufficient; but if great force is to be used the hydraulic press is put into action. This consists of a ram 4 in. in diameter, which raises the table against the mullet. Below the 4 in. ram, and entering the same chamber in which it works, is a second ram, about $1\frac{3}{4}$ in. diameter, forced inwards by a screw and hand lever. As this enters the chamber it will be seen that, on the principle of the hydraulic press, it displaces the water, and forces out the press-ram. A pressure of six tons is stated to be easily obtained, due to the difference in the diameters, multiplied by the power of the screw. The advantages claimed are, that there are no valves to get out of order, and that the power is applied continuously.

Messrs. Maw, Son and Thompson exhibited several articles. Pindar's pill machinery attracted considerable notice. It consists of a "piping press," into which the pill mass is placed and forced by screw pressure through holes in the bottom in long pipes, and a rotary machine consisting of two grooved cylinders, through which the "pipes" are passed and fall into a tray below in a pilular form. The registered stopper-guard consists



of an india-rubber ring passing round the stopper, and fastened by a brass clip to the lip of the bottle, as shown by the accompanying engraving. Other objects were a gas furnace, designed by Mr. T. B. Groves, in which the burners are so arranged as to give a great range of temperature, some Bunsen burners fitted with trivets, a label damper, and a powder-folding apparatus fitted with a ratchet by which it can be adapted to any size required. Messrs. Maw and Co. also exhibited one of Young's Poison Cabinets, described in this Journal, Vol. I., p. 876.

Messrs. Frazer and Green exhibited a bottle-guard designed by them. It consists of wire-work which fits over the bottle, so that in the event of its bursting while bottling waters, the glass is retained inside the wire casing. They also exhibited some poison bottles, the distinguishing features in which are the colour and the word "poison" printed beneath the label.

Messrs. Kay Brothers, of Stockport, exhibited a new oil-bottle invented by Mr. Sagar, the advantage claimed for which is that it is so constructed that every drop of oil runs back into the bottle, and thus avoids the waste, mess and dirt which attend the old bottle on the shelf.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 7, 1871.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

FUTURE PHARMACEUTICAL EDUCATION.

ALTHOUGH the Inaugural Address that is to be found in another part of the Journal was mainly devoted to a retrospective view of certain prominent features in the past life of our Society, one point was briefly referred to, which needs no power of second sight to be recognized as one of great importance in regard to the future, and demanding immediate consideration. We refer to the educational action of this Society. From the first, education has been the fulcrum upon which the Pharmaceutical Society has sought to exercise its influence in raising the character of the trade; and it is certain that the maintenance of a high educational standard is the only basis for advancement in the position of the pharmaceutist. That success has attended the efforts of the Society, we believe it would be unnecessary to insist upon, but much still remains to be done in this direction; and though hitherto, while the Society was a mere voluntary association, there was nothing inappropriate in its exercise of educational functions, the very success it has achieved has been of such a nature as to render those functions increasingly anomalous and their further continuance impossible.

The recognition of the Society as the examining body by which pharmaceutical competence was to be tested and certified, though that legislative act was to a great extent only prospective in its bearing, was none the less to be regarded as a notice that at some future time there must be an end to that school of pharmacy which has hitherto been the particular pride and glory of the Society. Consequently the members of the examining body have been gradually taking higher position among the Society's officers, and in that respect taking precedence of the professorial body. While this state of transition still prevails, it is imperative on all who have the interests of British pharmacy at heart to consider well what steps may be taken for securing to their successors that efficient means of instruction which will doubtless become even more indispensable than it is at present.

Closely connected with the question as to the future of the chief school of pharmacy, is the wider and perhaps even more important subject of provincial education, and we propose placing before our readers next week a paper on this subject, which we hope will excite an expression of opinions and criticism by many who have thought on the subject, and are able to point out the peculiarity of local circumstances that would have to be dealt with.

THE LONDON INSTITUTION.

WE have previously noticed the efforts being made by the Managers of the London Institution to make its resources useful in promoting scientific knowledge, and we are glad to learn from the announcement of Lecture arrangements for the coming season in the last number of the Journal of the London Institution, that these efforts are still to be continued. A course of lectures, on Elementary Physiology, will be delivered by Professor HUXLEY, another course of eight lectures on Elementary Chemistry will be delivered by Professor ODLING, and other courses of six lectures on Elementary Music and Elementary Botany will be delivered by Professor ELLA and Professor BENTLEY. Mr. P. L. SIMMONDS is also to give two lectures on the Raw Materials of our Manufactures, and, during the Christmas holidays, Mr. BROUGH will give a course of lectures on the Philosophy of Magic. Another interesting feature of the projected arrangements is the evening class for practical instruction in chemistry, under the direction of Professor ARMSTRONG. This is to commence early in November. The course will consist of twenty-five lessons, from six to half-past eight, and to many who cannot otherwise acquire a knowledge of chemistry, it will be an opportunity they would do well not to neglect.

OIL OF ANDROMEDA LESCHENAULTII.

AMONG the most interesting of the specimens presented to the Museum of the Pharmaceutical Society, and exhibited at the opening meeting, were those of the oil and carbolic acid, prepared by J. BROUGHTON, Esq., the Indian Government Quinologist, from the *Andromeda Leschenaultii*. The oil is almost identical with that obtained from the American species of Andromeda (*Gaultheria procumbens*), and we are inclined to be more hopeful than Mr. BROUGHTON, that if the oil could be produced at a sufficiently cheap rate it would meet with a sale. Certain it is that oil of wintergreen has been in great request by certain manufacturers of late. The extract from Mr. BROUGHTON's report,* kindly placed at our disposal by Dr. FORBES WATSON, will be of interest to our readers.

* Printed at p. 281.

POISON BY POST.

During the recent investigation into a charge of poisoning at Brighton, uncontradicted evidence was brought forward that some person or persons had forwarded anonymously packages of poisoned food by the ordinary means of conveyance, and that in one or two instances the recipients were sufficiently incautious to allow them to be eaten. It might have been hoped that these instances were exceptional, but Professor Attfield, in a letter to the *Times*, mentions two others which have come under his notice. We republish the letter because the warning contained in it is evidently necessary, but we demur to the inference drawn by him, for we think that where there is sufficient malice or mischief present to prompt to such an action, the difference of a few pence in the postage would hardly stay the hand. The suggestion that because the cases mentioned by Professor Attfield came under his notice during the existence of the late sample post regulations, therefore the caution becomes so specially necessary upon the introduction of a new parcels post, appears to have a slight tinge of the *post hoc propter hoc* style of argument.

"Just before the public was deprived of that short-lived boon, the old parcel post, a lady received by its means a few ounces of tea. Thinking the tea was sent for purposes of advertisement, and that a letter would follow, she, no doubt injudiciously, allowed the sample to be used at table. Every person who joined in that meal was more or less seriously ill, the tea, as proved by analysis, being dexterously impregnated with poison. The name of the latter, and the process by which evidently it had been introduced need not be disclosed, for I think it undesirable to add to the knowledge which the malicious only too easily gain from newspapers.

"The above circumstance I should have published at the time it occurred, but hoped it was a solitary case, and that another would not arise, but a similar one under the sample post has since come to my knowledge, and recently a still more serious affair of poisoned parcels of food has agitated the minds of all the inhabitants of a large southern town. It becomes my duty, therefore, on the re-introduction by the postal authorities of what is in effect a new parcels post to caution heads of families against using articles of food that may reach them through a channel in which all responsibility as to quality, purity, or harmlessness is lost.

"This letter need not occasion alarm or annoyance to any one. The householder is forearmed if forewarned. The dealer in food who proposes to advertise by help of the new postal tariff will see that, as the local guarantee of shop and person cannot travel with his samples, indiscriminate distribution of the latter is of questionable advantage. To the Post Office itself any profit on the carriage of a few specimens of such things as tea and cocoa is too small to be worthy of notice."

We learn from the *Times* that the Committee of Delegates representing the various districts abutting on the Thames, which, at the suggestion of the Privy Council, was organized a short time since for the purpose of instituting a systematic inspection of all vessels entering the Thames, and to arrange other joint action in view of the apprehended visitation of cholera, is now threatened with disruption, in consequence of the representatives of the East London parishes having very generally declined to make any contribution unless the assessment is based on the rateable value of the whole metropolis. This course has been approved by their constituents. An opinion has been expressed that the staff of officers is not large enough so to carry out the quarantine regulations of the Custom House as to prevent the importation of epidemic disease; and it is argued that as the expenses would be incurred for the benefit of the whole community, therefore the whole metropolis should bear the cost.

In connection with the East London district, we are pleased to notice that, in advertising for a person to fill the office of Inspector of Nuisances, the Poplar District Board of Works has evinced a recognition of the necessity of special qualifications for the right performance of the duties. It is stipulated that candidates shall possess a competent and practical knowledge of applied chemistry and mechanics, and it is intimated that they will undergo examination as to their qualifications by the medical officers of the Board. The person appointed will be required to devote the whole of his time to the carrying out of the several Acts, and in return the Board offer a salary of £150 a year. Applications are to be made before the 12th instant, and further information may be obtained on application to the Clerk of the Board.

The discovery of extensive salt mines at Stassfurt has created a mighty industry, and has naturally led to boring experiments in other parts of Germany, some of which have been rewarded by extraordinary results. Early in 1867 operations were commenced at Sperenberg, about twenty-five miles from Berlin, and after passing through 280 feet of gypsum and anhydride, rock salt was found, in October. A continuous layer of this has been bored through for a thickness of 2962 feet, the total depth reached at the end of last year being 3242 feet. In August, 1870, notwithstanding the war, another mine was sunk at a distance of 2000 feet from the first; and here, again, rock salt was reached at a depth of 369 feet. This Sperenberg salt deposit appears, therefore, to be by far the most extensive known. At Segeberg, in Holstein, rock salt has also been discovered at a depth of 940 feet; a stratum of salt, 24 feet thick, had already been passed through, when the boring tools broke, and it became necessary to start afresh. This was done at half an hour's distance, and salt was found at a depth of 310 feet, remarkable for its purity. From these preliminary trials, made at great distances, it appears evident that Germany may, in a short time, prove to be the country richest in salt, and these discoveries cannot fail to exercise a marked influence upon industry. All the salt mines are at present in the hands of the Government, the salt tax yielding a considerable share of the revenue; and it remains to be seen what effect in this respect the discovery of these enormous natural riches will have.

Transactions of the Pharmaceutical Society.

MEETING OF COUNCIL.

October 4th, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.
MR. EDWARDS, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Carr, Frazer, Groves, Hills, Mackay, Reynolds, Savage, Shaw, Smith, Stoddart, Williams and Woolley.

The minutes of the last meeting were read and confirmed.

The Report of the Finance Committee was presented, showing on the General Fund Account a balance in the Treasurer's hands of £735 1 9

And submitting for payment sundry accounts for rent, salaries, etc., amounting to £951 6 7

On the Benevolent Fund Account a balance of £290 10 1

Resolved—That the Report of the Finance Committee be received and adopted, and payments made.

The Report of the Benevolent Fund Committee having been read, it was

Resolved—That the Report be received and adopted. The Treasurer was requested to pay the several annuities to Christmas next.

A grant of twenty pounds was made to the widow of a deceased member.

The Secretary said that in the year 1865 the Council had paid a sum of money from the Benevolent Fund for the entrance of an orphan boy named Bentley into the British Orphan Asylum. The boy had now left the school, and the case was mentioned in the hope that some members of the Council might know or hear of some opening in which he might earn his livelihood.

An application was made for help by a widow in distressed circumstances, but as her husband was not registered at the time of his death, the Council much regretted that they were unable to give relief.

The Report of the Provincial Education Committee having been read, it was

Resolved—That a Register of Pharmaceutical Chemists and Chemists and Druggists be prepared and published according to towns and counties, and that the towns be arranged alphabetically, with the amount of population in each case.

Some discussion arose as to the compliance by the Nottingham Chemists' Association with the terms of the grant, and sufficient explanation was given by Mr. Atherton.

A grant of £10 was made to the Leeds Chemists' Association.

Resolved—That the Report be received and adopted.

The Report of the Parliamentary Committee having been read, it was

Resolved—That the Report be received and adopted.

Some cases of infraction of the Pharmacy Act were fully considered and further inquiry directed to be made.

Resolved—That the following having passed their respective Examinations, be elected Associates of the Society:—

MINOR.

Wilson, Thomas .... Blackheath.
Woods, Joseph Henry.......... Warrington.

MODIFIED.

Bullock, Frederick .... Manchester.

A Member who had paid his subscription for the current year, and the nominal fine of one shilling, was restored to membership.

Resolved—That the following Registered Chemists and Druggists be elected Members of the Society:—

Claridge, John Frederick ...... Warwick.
Hargreaves, William Henry .... Over Darwen.
